
16,746. Bedsteads, W. A. Beal, Halifax.

16,747. Billiard Tables and Pockets, J. W. Lane, Hounslow.

16,748. Flushing Water-closets, H. I. Sanders and W. Matthews, London.

16,749. Chucks, F. F. Simpson and J. T. Skidmore, Birmingham.

16 750. Water-tube Boilers, G. Richmond.—(*A. Worthington, United States*)

16,751. Folding India-rubber Eraser, W. A. Rees, London.

16,752. Tires, W. Howard, J. F. Sadler, and W. H. Dallimore, London.

16,753. Converting Rotary Motions, A. L. Gravier London.

16,754. Water Heaters, J. G. Smeaton and J. W. Bennett, London.
16,755. Cartridges, F. Brittain, E. L. O'Brien, and the Electrical Installation Co., London.
16,756. Furnaces, F. W. Golby.—(*J. Swiecianowski, Russia.*)
16,757. Tip for Billiard Cues, F. and C. Palfrey, London.
16,758. Utilising Bosh Cinders, &c., W. Roberts, London.
16,759. Treatment of Raw Sugar, C. M. Lafontaine, London.
16,760. Appliance for Beer Engines, S. J. Webster, London.
16,761. Horse Boot, W. Jenkinson, J. W. Squier, and G. E. Jenkinson, London.
16,762. Clay Baths, W. Cliff, London.
16,763. Ironing Stand, T. H. Schooling, London.
16,764. Sash Fasteners, J. Harris, London.
16,765. Sheep-shearing Machines, &c., M. Ford, London.
16,766. Crank shaft Arms of Looms, &c., J. Seed, London.
16,767. Actuating the Healds of Looms, L. Fish, London.
16,768. Saucers and Plates, J. Mohs and E. Zarek, London.
16,769. Thawing Frozen Food, E. M. Nelson, London.
16,770. Tires, S. McCormack, London.
16,771. Boxes, E. Prat, London.
16,772. Mitre Clamps, F. W. Hedgeland, London.
16,773. Apparatus for Aerating Liquids, J. L. Mendl, London.
16,774. Voltaic Batteries, D. G. Fitz-Gerald, London.
16,775. Electrolytic Cells, &c., D. G. Fitz-Gerald, London.
16,776. Tires, J. H. A. and E. T. Woods and W. T. Henley's Telegraph Works Company, London.
16,777. Cork Extractors, R. B. Gilchrist, London.
16,778. Motions for Shuttle-boxes, G. A. Falke, London.
16,779. Mounting or Supporting Labels, E. H. Hardy, London.
16,780. Sewing Machines, H. G. Ashley, London.
16,781. Manufacture of Material similar to Mosaic, R. Haddan.—(*J. Beaudequin, France.*)
16,782. Securing Corks, R. Haddan.—(*L. Murat, France.*)
16,783. Petroleum Lamps or Stoves, J. Hirschhorn, London.
16,784. Chimneys for Petroleum Lamps, J. Hirschhorn, London.
16,785. Making Cellulose Products, G. Jacober and A. Rabourdin, London.
16,786. Shoes, M. Freund, London.

*4th September*, 1894

16,787. Leading Lights for Narrow Channels, E. du Boulay, Isle of Wight.
16,788. Marking Drawing Material, C. W. Bailey, Liverpool.
16,789. Lighting Billiard Tables, W. Carter, Accrington.
16,790. Automatic Hand Camera, A. McLucas, Llanelly.
16,791. Umbrellas and Parasols, W. S. Cole, Bristol.
16,792. Musical Device for Hoop Sticks, W. H. Whitburn.—(*D. Whitburn, New Zealand.*)
16,793. Machine for Sawing Bands, J. Gazzard, Bristol.
16,794. Metallic Hampers, R. Leigh and H. Leigh, Bolton.
16,795. Collapsible Mud Guard, A. W. Penn, Gateshead-on-Tyne.
16,796. Easels, B. H. Heslop, Stockton-on-Tees.
16,797. Cord Fasteners for Parcels, F. E. Hollyer, Brentford.
16,798. Spinning Spindles, B. A. Dobson and G. Skinner, Manchester.
16,799. Adjusting Cycle Saddles, G. P. Mills and F. Easom, Birmingham.
16,800. Dress Clips for Lady Cyclists, A. B. Crowe, Banbury.
16,801. Railway Carriages, J. W. Dougal, Glasgow.
16,802. Fan for Spreading News of Public Interest, A. Lorber, Glasgow.
16,803. Water-proofing Boots, H. Hanson, Huddersfield.
16,804. A Sliding Cylinder, C. Harrison and J. H. Pearson, Peterborough.
16,805. Stud, Collar, and Tie Clips, W. J. Kerslake, Dublin.
16,806. Towing Bollard for Fishing Vessels, J. Norminton, Grimsby.
16,807. Railway Carriage Windows, T. Batty, Bradford.
16,808. Making Coverings for the Feet, T. Gare, Manchester.
16,809. Portable Weighing Machines, J. Holt, Manchester.
16,810. Waste-preventing Cisterns, W. Wheeler, Birmingham.
16,811. Frames for Photographic Pictures, H. Geh, Liverpool.
16,812. French Windows, &c., R. H. W. Rump, Glasgow.
16,813. Show Stand for Shopkeepers, T. R. Waite and H. C. Winham, Norwich.
16,814. Pencil Protector and Manifold Writer, A. Johnston, Glasgow.
16,815. Plates for Fencing Standards, J. Boyd, Glasgow.
16,816. Foundation Cylinders, W. Muirhead, jun., Glasgow.
16,817. Indicating the Weight of Gold, W. Whitehill, London.
16,818. Steering Ships by Hydraulic Power, A. Lafargue, London.
16,819. Front Fork for Velocipedes, E. Lycett, Birmingham.
16,820. Extracting Moisture from Steam, W. Adams, London.
16,821. Girdle, T. Le Beau, London.
16,822. Attaching Bands to Hats, F. W. Franklin, P. E. Taylor, and B. Franklin, Birmingham.
16,823. Expansion Valves of Engines, G. and P. Thornley, London.
16,824. Making Pin Tickets, C. A. Allison.—(*Thomas Manufacturing Company, United States.*)
16,825. Car Brake, R. T. Murray and C. M. Allen, London.
16,826. Automatic Pivot for Shelves, &c., J. Hens, London.
16,827. Advertisements, T. McGrah, London.
16,828. Tires, P. Davies, London.
16,829. Wick Tubes for Paraffin Lamps, J. Hall, London.
16,830. Motor, J. Roxburgh, London.
16,831. Combined Bedstead and Cot, R. Keyte, London.
16,832. Dental Suction Plates, J. Spyer, London.
16,833. Undershirts for Infants, L. Rubens, London.
16,834. Stone Crushers, P. W. Gates and C. L. Carman, London.
16,835. Stoppers for Barrels, H. H. Lake.—(*S. Schlangen and I. Neumann, United States.*)
16,836. Ships, L. M. Lincoln, London.
16,837. Feed-water Heaters, &c., H. G. Keasbey, London.
16,838. Feed-water Heaters, &c., H. G. Keasbey, London.
16,839. Boilers, H. G. Keasbey, London.
16,840. Paper Roll Holder, W. H. Clarke, London.
16,841. Book-rest, E. G. Passmore, London.
16,842. Substitutes for Skittle Balls, H. Oppenheimer, London.
16,843. Stoves, O. Keidel, London.
16,844. Photographic Shutters, W. Oehmke and C. P. Goerz, London.
16,845. Portable Book Rack, W. B. Drabble, London.
16,846. Treatment of Frozen Carcases, J. Atherton, London.
16,847. Tire Protectors, R. P. Majer, H. Mayler, and E. A. Allen, Liverpool.
16,848. Holding Devices for Laces, J. D. Lownsborough, Liverpool.
16,849. Organs, R. Hope-Jones, Liverpool.
16,850. Pill-making Machines, W. P. Thompson.—(*A. Colton, United States.*)
16,851. Underground Electric Railways, W. P. Thompson.—(*O. A. Enholm, United States.*)
16,852. Crushing Stone, W. P. Thompson.—(*Gates Ironworks, United States.*)
16,853. Crushing Stone, W. P. Thompson.—(*Gates Ironworks, United States.*)
16,854. Dynamo-electric Machines, S. H. Blake, London.
16,855. Inhalers, H. H. Lake.—(*F. Forné, France.*)
16,856. Apparatus for Lace Machines, J. Maiden, London.
16,857. Perforating Tapes for Telegraphy, P. B. Delany, London.
16,858. Ornamental Designs on Wood, C. Guattari, London.
16,859. Electrical Distribution, T. C. Coykendall, London.
16,860. Apparatus for Deadening the Shock of Collisions between Railway Vehicles, S. Freeman, London.
16,861. Fire-arms, T. R. R. Ashton and E. J. Kelly, London.
16,862. Magazines for Fire-arms, T. R. R. Ashton and E. J. Kelly, London.
16,863. Measuring Tap for Liquids, C. F. Archer, London.
16,864. Bottle, &c., W. Adams and F. R. Syms, London.
16,865. Pneumatic Tires, W. C. L. Holland, London.

*5th September*, 1894.

16,866. Machines for Knitting, G. F. Sturgess, Leicester.
16,867. Pneumatic Boxing Gloves, H. A. Evans, Birmingham.
16,868. Fixing Labels to Umbrellas, W. Corah, jun., Birmingham.
16,869. Spring Candlestick Socket, W. J. Jones, Glamorganshire.
16,870. Propeller for Torpedoes, J. M. Ross, New Deer.
16,871. Cutting Weft Pile Fabrics, J. Wilkinson, Manchester.
16,872. Transparent Flowers, W. Brierley.—(*F. E. Berta, Germany.*)
16,873. Watch Keys, D. Greenhalgh and W. Stockdale, Halifax.
16,874. Steamer, J. H. Leach, Darwen.
16,875. Forming Rolls of Clay, W. West and O. Y. Rhodes, Leeds.
16,876. Cycles, A. E. Hills, Birmingham.
16,877. Pneumatic Tires, E. H. Seddon, Manchester.
16,878. Way Bars for Phonographs, W. Lacey and A. Lomax, Blackpool.
16,879. Forming Bends or Curves in Tubes, W. Muir, Glasgow.
16,880. Securing Tires to Rims, J. W. O. Walker, W. Stelfox, and A. MacDonald, Glasgow.
16,881. Fastening Envelopes, F. C. Lynde, Manchester.
16,882. Form of Hand Protectors, H. J. Phillips, Ebbw Vale.
16,883. Roving Fibrous Material, C. Brigg, Bradford.
16,884. Chronographic Apparatus, F. J. Smith, Oxford.
16,885. Artificial Flying Birds, J. Harris, Dublin.
16,886. Protection of Lead Piping, J. A. Paskin and W. Ackroyd, Halifax.
16,887. Ships' Telegraphic Apparatus, H. Oliver, Liverpool.
16,888. Chairs for Young Children, T. H. Randolph, London.
16,889. Closing Shot Holes in Ships, E. H. Story, Manchester.
16,890. Textile Printing Machines, J. Wood, Manchester.
16,891. Horse Collars, A. F. McLellan and J. Fairie, Glasgow.
16,892. Cycles, R. Stephen, Glasgow.
16,893. Hair Curling Device, S. C. Russel, Glasgow.
16,894. Hems of Tray Cloths and Covers, J. Ellis, Glasgow.
16,895. Bearing Rein, A. Chopping and E. Pullen, Brighton.
16,896. Bottle Stands, J. E. Bingham, Sheffield.
16,897. Colliery Tub Attaching Gear, T. Archer, Newcastle-on-Tyne.
16,898. Apparatus for Measuring Quantities, H. S. Hele-Shaw, Liverpool.
16,899. Field or Kitchen Cooking Stove, A. C. Strains, Leith.
16,900. Billiard and Bagatelle Cues, R. Wilcox, London.
16,901. Combined Dinner Dish and Plate, H. Harverson, London.
16,902. Liquid Aeration Apparatus, J. T. Clarke, Harrow.
16,903. Elastic Wire Mat, R. Fischer and N. Buehler, London.
16,904. Carding Engines, E. L. Cockrell, R. Thew, and J. E. Stiebel, Manchester.
16,905. Automatic Delivery Machines, W. Oschwald, London.
16,906. Churns, J. Somerville, Glasgow.
16,907. Spikes, Bolts, and Nails, R. Frame, Glasgow.
16,908. Golf Practising Appliance, J. Turnbull, sen., Glasgow.
16,909. Cricket Bats, G. Halsey and W. S. Metcalfe, Enfield.
16,910. Equalising Furnace Draught, R. Gosling and B., H., and F. Hooker, London.
16,911. Combined Pipe and Tobacco Case, H. G. Parkes, London.
16,912. Electrical Insulating Compounds, G. E. Heyl, London.
16,913. Manufacture of Insulating Tapes, G. E. Heyl, London.
16,914. Filtering Apparatus, P. E. Hodgkin, London.
16,915. Folding Cardboard Box, A. Menzel, London.
16,916. Manipulating Electric Light, H. Taylor, London.
16,917. Window Sash Fasteners, G. C. Bullock, London.
16,918. Access Boxes for Electric Conductors, A. Fox, London.
16,919. Plug for Cisterns, F. Coates, Hastings.
16,920. Soap Holders, C. E. Challis, London.
16,921. Cycle Saddles, J. A. and H. A. Lamplugh, London.
16,922. Supporting Curtains, J. Harrington and F. Parker, London.
16,923. Regenerative Air Carboniser, J. F. Coutts, Woolwich.
16,924. Drain-pipe Testing Apparatus, H. E. Burnet, London.
16,925. Gas Lighting, H. Friedlander.—(*C. M. Lungren, United States.*)
16,926. Fasteners for Ladies' Hats, J. Brown, Belfast.
16,927. Gigantic Wheels for Recreation Purposes, J. W. Graydon, London.
16,928. Shoe Bow Grip, J. and H. Dartnall, London.
16,929. Attachment for Umbrellas, H. de Coursey Hamilton, London.
16,930. Elevating and Storing Sea-water, G. W. Blanks, London.
16,931. Door Stop, J. Marshall, London.
16,932. Interment and Disinfection of Corpses, G. Seegers, London.
16,933. Nailing Soles, P. A. Newton.—(*The Keats Maschinen Gesellschaft, Germany.*)
16,934. Coaling Ocean-going Vessels, B. C. T. Boyesen, London.
16,935. Attracting Fishes to the Bait, T. Raaschou, London.
16,936. Dress Preservers, D. R. Harvey, London.
16,937. Hydrocycle, H. Colledge, London.
16,938. Sterilising Water by Ebullition, E. Herscher, Liverpool.
16,939. Recording Electric Currents, H. Aron, Liverpool.
16,940. Attaching Aprons to Garments, F. F. Smith, London.
16,941. Ventilation of Rooms, &c., H. Sandwith, London.
16,942. Metallic Decorative Films, W. H. Coe, London.
16,943. Portable Ladder Platform, T. Langlois, jun., London.
16,944. Miners' Lamps, W. Green and H. Green, London.

*6th September*, 1894.

16,945. Lubricators for Steam Pistons, G. Bentley, Oldham.
16,946. Hair Curlers, H. H. Pearce, Birmingham.
16,947. Machines for Cutting Coal, W. Patterson, Gateshead.
16,948. Provision Knife, C. H. Nassau, Sheffield.
16,949. Curling and Crimping Hair, C. Hide, Worthing.
16,950. Circular Knitting Machines, W. Brown, Leicester.
16,951. Pistons, T. Davies and S. Davies, Liverpool.
16,952. Furnace Fire-bars, T. and S. Davies, Liverpool.
16,953. Inlet and Outlet Valves, J. H. Langlands, Dundee.
16,954. Bakers' and Confectioners' Oven, R. Wray, Bradford.
16,955. Machines for Damping Labels, A. M. Turner, Glasgow.
16,956. Warp Let-off Beams, E. Hollingworth and F. W. Gelder, Halifax.
16,957. Divisible Key Ring, D. Grayl and H. Brookes, Handsworth.
16,958. Pipe Connection, H. Robson and G. J. Calder, London.
16,959. Wheelbarrows, C. E. Edwards and E. Harris, Birmingham.
16,960. Station Indicator, F. H. Angles and J. Ward, Halifax.
16,961. Stock and Dies, W. Ward and T. H. Coles, Bristol.
16,962. Writing, Drawing, or Painting Ring, T. Reeves, Warwickshire.
16,963. Stocks and Dies, W. Ward and T. H. Coles, Bristol.
16,964. Compressed Air Cycle Tires, A. J. Bailey, Birmingham.
16,965. Kiln for Drying Oats, &c., J. Walworth, Bradford.
16,966. Machinery for Potters, E. J. Bradley, Newcastle-on-Tyne.
16,967. Cast Iron Bath and Towel Rail, H. S. Woodward, Falkirk.
16,968. Cultivators, J. Bamford, Birmingham.
16,969. Boots, E. S. Whitby, London.
16,970. Piano Attachment, A. Edwards, Woodford Green.
16,971. Loading Railway Trucks with Coke, A. Jobson, London.
16,972. Window-blind Appliances, A. Gough, London.
16,973. Making Non-conducting Material, J. C. Sewell, London.
16,974. Machinery for Rounding Square Wood, H. Greg, London.

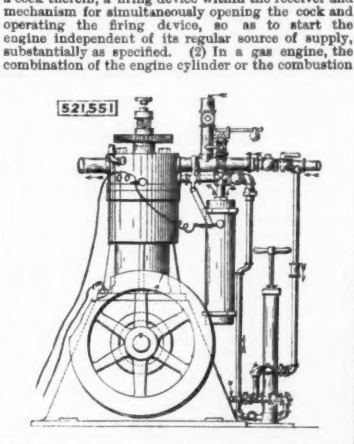
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**521,551.** Apparatus for Starting Gas Engines, *J. W. Raymond, San Francisco, Cal.—Filed April 10th*, 1893.

*Claim.*—(1) In a gas engine, the combination of the engine cylinder or combustion chamber thereof, the supplementary chamber or receiver charged with explosive gas or vapour under pressure, a connecting passage between the cylinder and the receiver, having a cock therein, a firing device within the receiver and mechanism for simultaneously opening the cock and operating the firing device, so as to start the engine independent of its regular source of supply, substantially as specified. (2) In a gas engine, the combination of the engine cylinder or the combustion chamber thereof, a supplementary chamber or receiver charged with explosive gas or vapour under pressure, a connecting passage between the cylinder and the receiver having a discharge cock therein, a compressing pump or other source of supply having a pipe leading to the receiver, and another pipe leading to the engine cylinder, said pump being operated so as to fill the receiver and prepare it between the intervals of starting the engine, a firing device within the receiver and leverage mechanism connected to the discharge cock and to the firing device, so as to operate them both simultaneously, substantially as described.

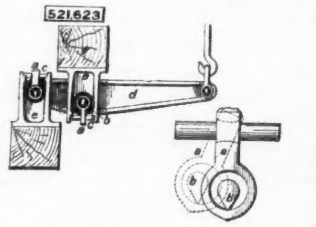
521,551



**521,623.** Weighing Scale, *H. Paddock, St. Johnsbury, Vermont.—Filed October 26th*, 1892.

*Claim.*—(1) In combination with a scale lever, loops having eyes in which the pivots of the lever rest, said loops having openings through them, and rigid horizontals rods *c* passing through said openings and directly supporting said loops, whereby said loops are capable of adjustment on said rods, and means for supporting the rods *c*, substantially as described. (2) In combination with a scale lever, having suitable knife edge pivots, loops *a*, having eyes in which the knife edge pivots rest, said loops having openings near their upper ends, horizontal rods passing through said openings, said openings tapering from both sides of the loops toward the centre, whereby the loops bear upon the rods only at one point, and are permitted sliding and swinging movement thereon, substantially as described. (3) In a railroad scale, in combination with the timbers *f*, the supporting standards *e*, the rods *c*, rigidly supported on said standards, the lever *d*, with pivots *b*, the loops *a*, having eyes in which the pivots rest, and having openings at their opposite ends through which the rods *c* pass, said openings being formed to give the loops a limited sliding movement on said rods, substantially as described.

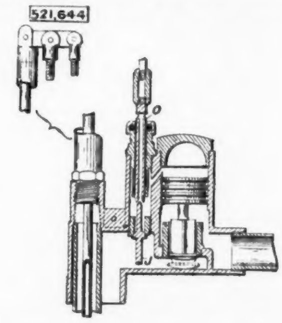
521,623



**521,644.** Automatic Controlling Device for Boiler Feeders, *J. Desmond, Detroit, Mich.—Filed August 26th*, 1893.

*Claim.*—(1) The combination of a steam supply valve, normally closed, a piston for opening said valve, an auxiliary valve for controlling a port supplying steam to the main valve piston, and a thermostat controlled by the height of the water for actuating said auxiliary valve, substantially as described. (2) The combination of the valve casing, the main steam valve therein, the cylinder above said valve, the piston therein, an auxiliary valve for controlling a supply port to said cylinder, the actuating mechanism for said auxiliary valve comprising a thermostatic device controlled by the height of the water, the hollow stem actuated thereby, having the vent O, and conical bearing *b*, on the stem of the valve J, controlling said vent, substantially as described.

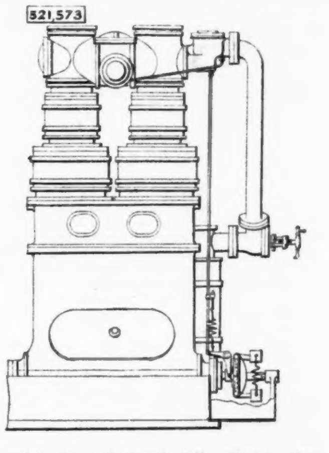
521,644



**521,573.** Expansion-gear for Engines, *M. H. Robinson, Thames Ditton, England.—Filed March 5th*, 1894.

*Claim.*—(1) The combination of a steam—or other fluid—engine cylinder, steam chest—pipe supplying steam thereto, throttle valve and governor acting thereon, hollow piston-rod of piston working in cylinder extending into the steam chest—sleeve in steam chest surrounding the end of the hollow piston-rod—oblique ports in sleeve and in piston rod—a cylinder open at one end to steam chest and at the other to steam supply pipe—a piston working therein and connections from the piston to the sleeve, whereby an inward movement of the piston turns the sleeve in a direction to make the cut-off earlier, and a movement in the opposite direction to make it later, and means for causing any inward movement to take place slowly while the outward movement is left free to take place quickly.

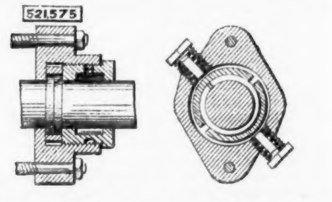
521,573



**521,575.** Rod or Valve Packing Box, *D. Spencer, Shenandoah, Va.—Filed July 22nd*, 1893.

*Claim.*—(1) The combination with a gland or casing, of compressible packing rings, curved jaws engaging opposite sides of the packing rings, adjustable guide-tubes passed from the outside through threaded perforations in the walls of the gland or casing and accessible from the outside thereof, and tension springs coiled within said guide-tubes and bearing at their inner ends against the jaws, substantially as specified. (2) The combination with a gland or casing, of compressible packing rings, approximately semicircular jaws arranged in contact with the outer surfaces of said rings and provided with radially-disposed stems, adjustable guide-tubes threaded in perforations in the walls of the gland or casing, and tension springs arranged within the guide-tubes and embracing said stems, substantially as specified. (3) The combination with a gland or casing, of packing rings arranged therein, a clamping device arranged in operative relation with said rings, and an annular bushing threaded into the outer end of the bore of the gland or casing, provided with an inwardly extending rim or flange to engage said clamping device and packing rings, and having an inner oil chamber communicating by radial perforations with an exterior oil channel, substantially as specified.

521,575



## ANTWERP INTERNATIONAL EXHIBITION.

### THE MARITIME SECTION.—II.

British shipbuilders and shipping companies are so frequently found at international maritime displays, putting themselves in evidence to such an extent as to belittle, if not completely eclipse, the representation made by continental or foreign firms, that an added and very special interest attaches to the maritime section of the Antwerp show through the very full representation and the close juxtaposition of exhibits both by continental and British firms. From this point of view, indeed, the section is not without its element of surprise for those who are ever ready to regard with scepticism or superior indifference the contentions frequently made as to the growth and seriousness of continental competition in shipbuilding. Throughout the section it is made abundantly evident that continental builders are accomplishing a large share of the building required by shipping firms in their own countries, and that even in regard to important work which we have hitherto been rather prone to consider highly specialised and "preserved," there is a distinct and growing competency, if not competition. That this is so in the matter of large powerful ocean mail passenger steamers will have been gathered from our article in our issue for July 6th, where references are made to the splendid exhibits of steamships recently built or now building in Germany, shown at the stands of the North German Lloyds, the Vulcan Shipbuilding Company of Stettin, and the Hamburg American Company. But it is also true as regards fast paddle steamers and the machinery by which they are propelled; a fact strikingly illustrated at the stand of the Société Anonyme John Cockerill in the main buildings, containing the models, plans, and spare shafting of their successful Channel steamer Marie Henriette, and also at their stand in the machinery-in-motion section, where a full-sized set of marine twin-screw engines are seen at work. The latter is one of a set of twin-engines of 1600 indicated horse-power, destined for a cargo boat of 3500 tons now on the stocks at the Société's shipyard at Hoboken, a little way out of Antwerp. The engines are at work driving a length of thrust shafting and a heavy four-bladed propeller. The steamer these engines are destined for forms one of a fleet of ten steamers owned by the Société, and employed in importing ore and exporting manufactures turned out from their great works at Seraing. This fleet, it will be easily understood, enables the company to gain direct experience in marine engine working, and to base designs on the experience thus acquired. Besides the models and plans of the Marie Henriette shown at the stand in the maritime section, there are about a dozen other models of the vessels built at the company's shipyard. These include the p.s. Comte de Flandre, shown as representative of the type of mail steamers of 1868, the sister ships, Prince Albert, Ville de Douvre, and La Flandre, which typify the mail boat of 1888.

The model of the Marie Henriette, of course, exemplifies the mail-boat of the present day; and, in addition to the full models of her shown at the Société's two stands, beautifully finished deck and other plans are ranged round the tables on which the models are placed. As between builders and owners the satisfaction in the Marie Henriette seems to be mutual; and at the present time there is being laid down in the Hoboken yard an additional paddle steamer for the same important Channel service. The new vessel is to be some 40ft. shorter than the Marie Henriette, the reason for this being chiefly concerned with the question of facility of working and movement in approaching and leaving piers.

Belgium's deep interest in the Congo, and the work of colonisation which has been carried on there for years, has necessitated the construction, trans-shipment, and re-erection of many light-draught river paddle steamers, launches, canoes, &c. Most of these have been built by the Cockerill Company, and the conditions as to draught and portability, involving many somewhat nice problems, have been well met by the manager at Hoboken, Mr. Geo. Rickard, M.I.N.A., and his subordinates. A collection of models representing this class of work, also actual steel boats being carried by natives in portable sections, are shown in the Congo Pavilion in the outside grounds.

In the matter of continental competition in building large sailing ships and heavy deadweight carrying steamers, the stand of Messrs. Tecklenborg, shipbuilders, of Bremerhaven, deserves prominent mention. A varied and attractive collection of models is here shown, all of them representing vessels built during the past three and a-half years. The dimension and tonnage of some of these will be evidence enough of the important character of the work carried on by this continental shipbuilding firm. The series includes the s.s. August Korff, built this year, of 5400 tons, and 354ft. long, and the s.s. Placilla, built in 1892, of 4420 tons, and 310ft. long. Besides these there are several others of slightly less tonnage, also models of sailing ships and of various kinds of river paddle steamers. Messrs. Tecklenborg, it will be of interest to state, have lately received an order for a five-masted steel sailing vessel, which, when completed nine months hence, will be the largest sailing vessel ever constructed, being considerably larger than the ill-fated Marie Rickmers, built three years ago by Messrs. Russell and Co., of Port Glasgow, and lost on her first voyage. The new vessel will certainly be the largest sailing ship afloat, her dead-weight carrying capacity being designed at 6150 tons, and register tonnage about 4280 tons. The register tonnage of the Marie Rickmers was 3813 tons, while that of the largest sailing ship now afloat—La France, belonging to the fleet of Messrs. A. D. Bordes and Son, of Bordeaux, and built by Messrs. D. and W. Henderson, Partick—is only 3784 tons. The new vessel, which will be 365ft. in length, is to the order of Messrs. F. Lacisz and Co., of Hamburg.

Mention of the name of Messrs. Bordes suggests some reference to another fact, interesting as showing the growing continental competition in shipbuilding. This enterprising firm, whose ships have hitherto mostly been built on the Clyde, have ordered no fewer than five large four-masted ships, each of 4000 tons deadweight capacity, from French builders. Three are to be built at the Ateliers de la Loire, and two at La Seine by the Forges et Chantiers de la Meditérranee.

The celebrated French firm of Schneider et Cie., Le Creusot, at their interesting stand in the French section, make, in addition to a fine display of artillery, war material, guns, test-plates, &c., an attractive show of photographs, and small working models of marine engines turned out from their works. Photographs are shown of the triple-expansion engines of 13,500 indicated horse-power for the first-class cruiser Charles Martel, and of 8300 indicated horse-power for the cruiser Chanzy. Beautifully constructed small-scale models of torpedo boats, with all internal details in section, also models of torpedo boat engines, and engines for the first-class protected cruiser Alger, of 8000 indicated horse-power, are items exhibited by this firm, of deep interest to all in any way connected with naval design and construction.

Wall and floor space at one side of the Hamburg-American Company's pavilion is occupied with exhibits by the Hamburg shipbuilding firm, not unknown in Britain, of Messrs. Blohm and Voss. They show a full model of s.s. Gintra, built by them in 1889, of 2600 tons, 1600 indicated horse-power; also a half-model of the twin screw Wittekind, of 364ft. in length. From this it may be inferred that the capabilities of their works are of no mean kind; a fact to which further testimony is borne by the display of a series of large photographs showing their shipyard, engine shops, quays, and pontoon dock. One set of photographs illustrates the capabilities of the latter, representing it at a time when it was occupied by the s.s. Bayern, of the North German Lloyd fleet, drawn asunder, and under process of being lengthened 50ft. amidships. The Sachsen, another of the North German Lloyd fleet, was similarly treated by Messrs. Blohm and Voss last year, and now we understand a third steamer, the Preussen, is also being lengthened amidships, the added part in her case being 70ft.

Just outside the Hamburg-American pavilion the Flensburger-Schiffsbau Gesselschaft have an elaborate display of beautifully drawn and coloured plans of the vessels of various kinds they have built, several of these being between 320ft. and 350ft. in length. Included in the collection is a set of photographs, showing the firm's off-shore dock—Clark and Stanfield's patent—with a large screw steamer in place upon it.

Near the above is the stand of the Hansa Shipping Company, of Bremen, at which are shown models of some six or seven of the company's fleet; one being that of the Harsburg and Marienburg, built during the present year by the Flensburg firm. Other models are those of the Rothenfels, Lindenfels, and Stolzenfels, the two former built this year and the latter last year, by Sir Raylton Dixon and Co., of Middlesbrough. These are spar-decked screw steamers of 327ft. in length, fitted with triple-expansion engines by Messrs. Thos. Richardson and Company, West Hartlepool.

Various other continental shipbuilding firms and shipping companies are represented by exhibits, of only a few of which mention need be made. The Koninklyke Maatschappy De Schelde, of Holland, shows an exceedingly varied collection of wall models of vessels built by them, including cargo screw steamers, paddle passenger steamers, sailing ships, and torpedo craft. The Nederlandsche Stoomboat Maalschappy, of Rotterdam, shows half models of s.s. Java built in 1885, also of s.s. Van Dieman, built in 1890 for passenger and cargo service between Holland and her colonies. The Société Anonyme pour l' Importation des Huiles de Graissage show models of several of their boats, including a half model in glass case of the s.s. Erivan, built by the Palmer Company, of Jarrow, last year, and capable of carrying an oil cargo of 2850 tons. A feature of this exhibit is that the back of the model coincident with the centre longitudinal plane of the ship, is all filled in with a linear representation of the structural framework, &c., in an instructive way afterwards to be noticed in connection with a still more interesting model of the same class, shown by Sir William Armstrong, Mitchell and Co.

Mention of this eminent firm reminds us of our having deferred notice of the exhibits from the North-east Coast and other British districts, and this we will proceed to overtake. Firstly, however, we must make reference to the manner in which Lloyd's Register Society is represented in the Exhibition. Indirectly, of course, most of the models sent by British builders and shipping companies, and a goodly proportion of those shown by continental firms, are representative of this great society's operations and scope, as the term "100 A1 at Lloyds" is mostly applicable to them. At former exhibitions Lloyd's Register has put itself more directly in evidence as "guide, councillor, and friend" in the matter of ship construction, by organising a large display of models of vessels built under its rules and survey, selected from the archives of the actual builders, and lent by the latter for the purpose; but, in the present instance this powerful institution has confined itself almost entirely to displaying the literature it has compiled and issued during the whole period of its existence. This includes, of course, the rules for the construction and classification of wood, iron, and steel sailing ships and steamers. Volumes of the register, bearing dates from 1834 to 1894, are on view, and the contrast between the thin and modest-looking volume of the early date and the bulky tome of the latter—comprising, indeed, not only one, but several separate parts—is in itself, sufficiently eloquent testimony to the wonderful growth and development of the Register. The Society's successful yacht register, inaugurated in 1878, is also put in evidence in the shape of the annual volume of rules and the list of yachts afloat classed and unclassed. In glass cases at each side of the bookcase containing this library, is an interesting collection of electro-plated models of anchors of both the stock and stockless kinds. Altogether, some thirty-four examples of anchors, chiefly the stockless patterns, are shown, each bearing the name, if not the "stamp of originality," of the patentee. On the wall above and around the cases are framed diagrams showing the methods approved by the Society of constructing watertight bulkheads, as regards side-framing, stiffening, &c., for ships of various breadths and depths.

Noteworthy as a contribution to the literature of shipping and shipbuilding, and highly appropriate in an international collection of maritime exhibits, is the display made by Captain H. Paasch, Lloyd's surveyor for the Belgian ports, of the new edition of his well-known valuable work, "From Keel to Truck," a marine dictionary in English, French, and German. The present is an extension, revision, and to some extent a blending of his work of that name, published nine years ago, and his subsequently published "Marine Encyclopædia." Within a neat glass case, embellished by medals and badges of honour which have been conferred upon Captain Paasch by various high personages and institutions during a comparatively long and eminently useful lifetime, a number of the volumes are displayed, open at different parts in such a way as to give some idea of the varied and exhaustive contents. Ships and shipping concerns, it need scarcely be remarked, are among the oldest interests in the world, and every important nationality in Europe having a seaboard has supplied, from time to time, some of the terms now in common use; but it is not to be supposed that the birth and growth of terms in this connection has by any means ceased. Not only has the introduction of iron and steel totally overthrown numerous terms formerly in use, but new types of vessels are continually being schemed out and constructed, and new details introduced for their more efficient working. This restless progress, of course, involves the creation of new terms or a modification of the old, rendering it necessary to revise a maritime dictionary at comparatively short intervals, if accuracy and comprehensiveness are desired. The large amount of additional matter and the painstaking accuracy observable in the new edition of Captain Paasch's work, are proofs that he is continuously occupied watching the development of the mercantile marine, and making intelligent note of the constant growth and changes going on. It is not often that a busy and able man connected with the maritime profession is found at the same time combining linguistic and literary capacity, while, as Captain Paasch points out in the preface to his new work, a linguist merely, no matter how capable, if wanting in professional qualifications, is extremely apt to fall into serious error in translating technical terms. Captain Paasch's varied experience places him in a unique position in this respect; and not only as linguist and literary expert, but as seaman, naval architect, and marine engineer he has compiled this most valuable work of reference in the three principal languages—a work which appears to stand alone in the essentials of completeness and trustworthiness. Strongly and handsomely bound, the volume consists of 800 pages of letterpress and illustrations—500 of which pages contain general terms in English, French, and German in parallel columns; 206 pages are occupied by illustrations, with the corresponding explanatory letterpress in the three languages; copious indices, also in triple language, occupying altogether about 70 pages, complete the work.

Sir William Armstrong Mitchell and Co., of Elswick-on-Tyne, occupy a large space with numerous highly attractive exhibits. One in particular is an unfailing source of keen, though somewhat melancholy interest, being a splendidly finished model of the ill-fated warship Victoria. The model proper, which is 30ft. in length, only represents half the ship, but by a mirror-arrangement at the back, the other half is completed by reflection, and from a platform erected in front the whole can be conveniently inspected. The surface of the water in which the vessel is represented as floating, is counterfeited by rippled glass, and extended on booms all along the vessel's length is a protective torpedo netting. The whole exhibit closely counterfeits the warship in every detail, as she lay at sea ready for any surprise from an enemy. Another model of special interest is that representing this firm's conception of a modern Atlantic mail and passenger express steamship. She is a twin-screw vessel, 540ft. by 62ft., designed for a speed of 22 knots. There are two funnels, oval in shape, and two pole-masts with fore and aft canvas only. The model shows the vessel to have three principal decks, with a hurricane or promenade deck almost the full length, from front of poop to front of forecastle decks, both of which are of the turtle-back type. Notable characteristics of the design of the hull are the ease and sweetness of the lines, roundness of bilge, large bilge keels being fitted for half the length, and the sweeping-up of the line of keel, not only at the forefoot, where this has long been the practice for purposes of easy steering, but at the heel or after part of the hull as well. The tendency to lop off needless weight and surface at the heel of fast screw steamers—corresponding to the "deadwood" in the structure of old-time wood vessels—is growing more and more into fashion, as witness the sketches given in our previous article of the new North German Lloyd twin-screw steamers being built by the Vulcan Company, of Stettin, and of the new Union twin-screw liner Norman, built by Messrs. Harland and Wolff, given in our issue of 27th ult. Considerations connected with a free "run" to the propellers and of enabling them to work in undisturbed water as much as possible, would seem largely to account for these modifications. It is noteworthy, at least, that although quite modern, continental builders are not slow to adopt the changes, and even seem to lead the way, by making wider departures from conventional practice than home builders. Alongside the Atlantic Express model is a half model of one of the petroleum tank steamers, in the construction of which Sir William Armstrong, Mitchell and Co. have had large experience. This is a highly instructive exhibit, as the back of the model, coincident with the centre longitudinal plane of the vessel, is all sectioned off to represent the actual construction: floors, beams, frames, pillars, bulkheads, &c., everything in fact connected with the interior structure of the vessel being minutely lined and shaded. The holds are hollowed out as in the actual ship, and linear representation made of side frames, hold-side stringers, tank-top plating, and bulkheads, with the modes adopted of stiffening and rendering them oil and water-tight. On the wall near this model is a set of six half models of petroleum vessels built for service in the Caspian, Azof, and Black seas. The whole of the vessels are fitted with special appliances for burning petroleum as fuel, and several of them have been constructed for the carriage of petroleum in bulk, with powerful pumping appliances, so that the entire cargo can be loaded or discharged in a few hours. Other merchant steamer models shown by Armstrong, Mitchell and Co. are s.s. Roland, s.s. Mark, and the twin screw s.s. H.H. Meier, of 11,000 tons displacement, all built for the North German Lloyd Company. Of Government vessels built by the firm, models are shown of the Argentine cruiser 25 De Mayo, built in 1890 from the designs of Mr. Philip Watts. She is 350ft. in length, 43ft. beam, and 16ft. draught; 3180 tons displacement, and 14,052 indicated horse-power. Under forced draught she attains a speed of 22½ knots, and under natural draught 21¼ knots. There is also a model of the Japanese cruiser Yoshino, built last year, 360ft. in length, 46ft. 6in. beam, and 17ft. draught; 4158 tons displacement, 15,750 indicated horse-power, and 23·03 knots speed on trial. Her radius of action at full speed, with natural draught, is 2000 knots, and at 11 knots speed it is 8000 knots. Both these vessels have been illustrated in our pages.

Facing Sir Wm. Armstrong, Mitchell and Company's exhibits is the pavilion occupied by the Palmer Shipbuilding Company, of Jarrow, which makes a magnificent show with a collection of models, paintings, and photographs of its vessels, as well as a collection of limestone and coke, Cleveland and Spanish ironstone, pig iron of different classes, test bars, and sections of rolled beams. Of warships it shows models of the first-class battleship Resolution, of rolling notoriety, the second-class cruiser Pique, and of the recently completed Spanish cruiser Infanta Maria Teresa, built at Bilbao. An attractive item on the stand is a large marine painting showing, afloat, the various types of war vessels built by the company for the British and other Governments. Besides a further variety of cargo and passenger steamers the stand contains a working model of a triple-expansion engine of 1100 indicated horse-power, to a scale of 3in. per foot. This model—which is nevertheless big enough for a good-sized yacht—is exhibited driving a screw propeller 4ft. in diameter, the diameter of shafting being 2¾in.

Messrs. C. S. Swan and Hunter, of Wallsend-on-Tyne, are represented by a collection of full and half models in glass cases, the vessels chosen for illustration in this way being mostly the large deadweight carriers for trans-ocean service, so many of which the firm are now producing. One of these is the Maori, completed in the autumn of last year for the Shaw, Savill, and Albion Company, built and specially insulated for the carrying of frozen meat between New Zealand and England. The deadweight capacity of the Maori is 7000 tons, and speed 12 knots, the engines having been fitted by the Central Marine Engine Works, West Hartlepool. The firm also show photographs of the exterior and interior of several of their other vessels, and views of the large pontoon dock built by them some two or three years ago for the Tyne Pontoon and Dry Dock Company.

Messrs. Hawthorn, Leslie and Co., both by models and large photographs, convey to visitors some idea of the importance of their productions in the way of marine engines and ships. The models shown include the p.s. Roumiantzeff, built for the Russia Steam Navigation and Trading Company, of Odessa; the s.s. Hevelius, built for the Liverpool, Brazil, and River Plate Steam Navigation Company, Messrs. Lamport and Holt, managers; the twin s.s. Petersburg, built for the Russian Volunteer Fleet; and the s.s. Alagoas, built for Lloyd Brazilliers, Rio de Janeiro. Amongst the photos of engines shown is one of the triple-expansion engines of 10,000 indicated horse-power fitted in the s.s. Sarator and Orel, of the Russian Volunteer Fleet; one of the triple twin-screw engines of 9500 indicated horse-power fitted in H.M. protected cruisers Sybille, Æolus, Brilliant, Bonaventure, and Centurion; and one showing the triple twin-screw engines of 7500 indicated horse-power fitted in H.M. protected cruisers Katoomba, Mildura, Wallaroo, and Pallas.

Sir Raylton Dixon and Co., of Middlesbrough, have an attractive stand, at which they show some ten or a dozen well-finished half models in glass cases. The vessels represented are mostly of recent build, some indeed not yet completed. Notable models are those of the s.s. Ceylon, just completed for the Peninsular and Oriental Company, and designed to carry about 6000 tons deadweight, at a speed of over 13 knots; the s.s. Leopoldville, of 3460 tons, built this year for the African Steamship Company's direct-service between Antwerp and the Congo; and the Hotham-Newton, also built this year for petroleum carrying purposes.

Not a few shipbuilding firms, both on the Clyde and elsewhere in Britain, have contented themselves with sending single models, representative of the class of work undertaken by them. Thus we have Messrs. A. and J. Inglis, of Pointhouse, Glasgow, exhibiting a handsome full model of the large s.s. Taroba, built for the British Indian Association, and fitted by the builders with triple-expansion engines; Messrs. The London and Glasgow Shipbuilding Company, of Govan, showing a half-model in glass case of s.s. Foreland and Goodwin, built for the Clyde Shipping Company, and fitted with engines by the company, having boilers worked under Howden's system of forced draught. Messrs. Blackwood and Gordon, Port Glasgow, showing half model of s.s. Austerland of 950 tons, built in 1886 for Messrs. G. Bethell and Co., and Trinder, Anderson and Co. Messrs. Wigham, Richardson and Co., of Wallsend-on-Tyne exhibiting a well finished model of the s.s. New Londoner, completed by them a few months ago for the Tyne Steam Shipping Company, and Messrs. Joseph L. Thomson and Co., of Sunderland, showing the s.s. Coogee, built for Messrs. Huddert Parker and Co., of Melbourne. To Mr. Jas. Laing, of Deptford Yard, Sunderland, the maritime section is indebted for a model representing what is happily designated "Ye Olde Schoole" of passenger ship, being that of the Vimiera of 1037 tons gross and 841 nett, built at the Deptford Yard in 1850. The presence of this model, typical of the wooden sailing passenger vessels of five decades back, forms a striking contrast to the magnificent steamship Campania, whose splendid model is not far off.

Messrs. R. and H. Green, of Blackwall, in a neat stand, show a model and items of detail of the steam lifeboat Duke of Northumberland, the predecessor of the recent and improved boat of this type, the City of Glasgow, bought by funds subscribed in the Scotch commercial capital, and handed over this year to the National Lifeboat Institution.

Messrs. W. B. Thompson and Co., Dundee, show a model of a pleasure steamer, in all respects to outward appearance typical of the ordinary paddle river passenger steamer. A closer scrutiny, however, discovers that besides being a paddle, she is a twin screw steamer as well, the screw being carried at the end of a long length of outside shafting—long, because of the fine "run" of the hull. The idea of the exhibitors has apparently been to combine the steadiness and comfort usually appertaining to the paddle steamer, with the augmentation of speed due to the twin screws. The model is merely a design, but whether or not an actual vessel is likely to be built does not appear.

Channel passenger steamers, it goes without saying, are plentifully represented by models either at the stands of their owners or builders. The keen interest centring in the models of the Dover and Ostend Packets, Leopold II. and Marie Henriette, has already been commented upon. Scarcely less interest attaches to the models of the Channel twin-screw steamers Chelmsford, Berlin, Amsterdam, and Vienna, built and building by Earle's Shipbuilding Company, Hull, for the Harwich and Hook of Holland service of the Great Eastern Railway Company. The Chelmsford was built last year, and the Berlin, which is a sister ship, with the exception that she has a little more length and beam, was completed in the spring of the present year. The remaining two vessels are nearing completion at the hands of Earle's Company. All the four vessels are slightly over 300ft. long by 36ft. beam, and they measure about 1750 tons. They are fitted with two separate sets of triple compound engines of some 5000 indicated horse-power, the speed attained being over 18 knots.

The London, Chatham, and Dover Railway Company are represented by a model of its swift Dover and Calais Channel steamer Empress, built in 1887, as typical of the consorts in this service, the Invicta, the Victoria, and the Calais-Douvres, the latter a recent addition credited with 21½ knots speed.

At its stand, among the ship models, the Darlington Forge Company makes a most effective display of its manufactures in steel and iron forgings, steel castings, &c., by way of electro-plated models, to scale, of actual items turned out within recent times. These include cast steel stern frames, sterns, propeller and shaft brackets, rudder frames, crank webs and pins, also forged steel crank-shafts, thrust and tail-end shafts, connecting rods, &c. The electro-plating of the models gives them a more toy-like than work-a-day appearance; but that the actual productions which they represent were of the first importance from a scientific and industrial point of view is sufficiently borne out by the mere mention of the vessel's names of which they went to form a part. Amongst the most striking of these items we may note Harland's cast steel hanging stern frame, rudder and shaft brackets, as fitted in the s.s. Civic, of the White Star Line. The actual stern frame weighed 17 tons, rudder, 11½ tons, and brackets 12 tons. Another notable item is that of the model—to ½in. scale—of the cast steel stem of H.M.S. Majestic and Magnificent, the actual stem having weighed 27 tons. The cast steel stern-frames and rudder of the same vessels are represented, also cast steel stern-frame and shaft brackets fitted into s.s. Gaul, Goth, and Greek, of the White Star fleet. The cast steel stern-frame and rudder of the s.s. Australia and Himalaya of the P. and O. fleet, are also shown. Other items are a four-throw crank shaft of the "built" description, of 18¾ tons, cast steel crank webs and pin, and forged steel shaft ends, and forged steel crank shafts of H.M.S. Royal Sovereign, and cast steel balanced rudders for H.M.S. Andromache and Apollo.

## HARBOURS AND WATERWAYS.

*Dock and harbour finances.*—The reports of the two large London dock companies for the past half-year are on the whole satisfactory. The foreign shipping entering the docks in London increased by 370,475 tons, as compared with the corresponding period of 1893; and of this the London and St. Katherine's and East and West India Docks secured 170,907 tons as their share. The net revenue earned by the Joint Committee amounted to £266,396, as compared with £247,738 in the corresponding period of the previous year. The articles handled, it seems, have been of a more paying description, and owing to economy and good management the net revenue has improved by £20,000. It is to be gathered from these reports and the chairman's speech, that, although the tendency for vessels to enter the Port of London with part cargoes is on the increase, and the Thames has lost much of the transhipment trade of former years, yet there is no reason to fear that the great volume of business exhibits any very marked change. The Joint Committee is endeavouring to cultivate trade by providing better accommodation for the Australian meat trade, and by erecting refrigerating meat chambers at the Victoria Docks and at Smithfield. The importation of butter from New Zealand is also a growing trade. An arrangement exists between the dock companies in the Thames by which the various branches of trade are kept more or less to those parts of the port where they have in the course of time found their home, and the agreement relating to this, which has recently expired, has been renewed by the Joint Committee with the Millwall and Surrey Commercial Companies.

At Millwall Docks the report for the half-year shows that the improvement which commenced last half-year has continued. The company's warehouses have been well filled, and the tonnage greater than since 1888. The imports of hay, which had been very large during the winter, had fallen off. One-tenth of all the grain imported into the kingdom passes through these docks, and it is expected that the importation will be heavy this year. The relations of the company with its men continue to be satisfactory, but the effects of the coal strike are still continued to be felt.

At Dundee the condition of affairs has not been prosperous, the deficit on the year's working amounting to over £8000. The revenue is less than was estimated at the beginning of the year by £3738, and the expenditure is greater by £5375. In consequence of this deficiency it has been determined to reduce the expenditure all round; where possible works are to be suspended, and a large number of men will be paid off.

At the Bute Docks the net revenue for the half-year is sufficient to pay a dividend to the ordinary shareholders at the rate of 3 per cent. per annum. At Falmouth the gross revenue for the half-year is £2000 in excess of that for the corresponding half-year of 1893, due to an increased number of vessels putting in for repair and using the graving dock. The general import trade continued to develope.

*Thames Conservancy.*—The annual report for the year 1893, which has recently been issued, shows that forty-one sunken vessels were raised by the Conservators' wreck raising plant, of which five were steam vessels, measuring 2777 tons, and thirty-six were barges of a tonnage of 1376. The annual cost of the wreck service is £2469. The total expenditure for the year amounted to £110,372, the principal items being for interest, £3314; mooring service, £9480; dredging, £13,998; harbour service, £8560; repairs of piers and wages of staff, £10,538; management and engineering staff, £15,729. Amongst the special expenses are for the new offices on the Thames Embankment, £7713; Richmond Lock and Weir, £12,000. The cost of maintaining the upper navigation amounted to £19,710. The receipts in this department include £16,665 paid by the London water companies.

*The Clyde.*—The revenue of the Clyde Trustees for the past year has been £3500 in excess of any previous year. From the report presented to the trustees it appears that the tonnage of vessels has increased from 1,448,869 in 1860 to 3,515,267 in 1893, and of goods from 1,192,475 to 4,879,312. The number of tons of goods discharged for each lineal yard of quay space in 1860 was 322·9 and in 1893 434·4. The returns seem to indicate that the larger vessels now in use discharge a greater quantity of cargo for each yard of quay than was formerly the case. At the present time trade is very disorganised owing to the strike of the Scotch coal miners. Coal has been freely imported from England, but many firms have closed their works on account of the high price which has to be paid. In common with other industries the Clyde Trust has been seriously handicapped by the scarcity of fuel; and English coal has had to be procured to keep the dredgers and ferries going. An idea of the total loss to the Scotch mining industry may be gathered from the fact that in less than eight weeks about 9000 tons were brought from England for this purpose alone. The quantity of material dredged during the past year amounts to 2,310,980 cubic yards, which is about half a million tons more than in the previous year. About half of this was taken from the new Cessnock dock, and the remainder from the channel of the river. The channel is being widened about 70ft. at Newshot Island for about half a mile, the dredged material being placed in the old back channel and the low ground adjoining. Three new hopper barges of 1200 tons each have been added to the dredging fleet. The number of passengers carried by the ferry boats belonging to the Trust in the past year was 12,225,645, and 233,167 vehicles, the revenue derived from this source being £32,803.

*Aberdeen.*—The Harbour Trustees, after receiving a report from Mr. Wake, C.E., of Sunderland, have approved of a scheme of improvement submitted to them by their engineer, Mr. Smith, which includes the widening of Trinity and Regent quays for a length of 400ft. in each case; Victoria Dock quay for a length of 700ft.; and the construction of four new sheds, the total estimated cost being £32,580; also a new swing brdige to replace Trinity Bridge. This bridge is to carry a double line of rails, and it is proposed to work it by hydraulic machinery actuated by a gas engine, the estimated cost being £13,411.

*Peterhead.*—During the past year the breakwater has been extended 105ft., and the foundations of a further length of 40ft. prepared. The foundation work has involved a great deal of rock excavation and levelling under water by divers. Convict labour has been employed in removing about 5400 cubic yards of decomposed rock from the quarry during the winter months. The number of men employed during the past year was: freemen, 133; convicts, 229; warders and guards, 28.

*Bridgwater.*—The Corporation have issued a report with reference to the ship canal which has been projected for the improvement of the port, and have advised that an engineer accustomed to works of this description should be called in to advise on the matter. There are two suggestions which have received consideration: (1) To cut a canal 2½ miles long through the lowlands to the Toven, having a depth of 22ft. (2) To straighten the course of the river by cutting through the existing bends.

*Portsmouth.*—Mr. Kinipple has sent in his report as to the proposed improvements of the Camber for the harbour authority. The report gives three alternative schemes, the cost varying in amount from £30,000 to £77,000, the scheme being so designed that the work may be done in sections, starting with an initial outlay of the smaller amount.

*Barry Dock.*—The contract for the new dock has been let to Messrs. Price and Wills, and operations have been already commenced. It is stated that Lord Windsor intends making considerable improvements for the convenience of summer visitors to Barry Island by improving Whitmore Bay, and making a promenade round the island.

*East Coast shipping disasters.*—The ports on the East Coast seem to have been singularly unfortunate recently. At Lynn the harbour authorities, after the lapse of considerable time and the expenditure of about £18,000, have only recently completed the removal of the steamship Wick Bay, which was wrecked in the Lynn channel about five miles below the dock. In the Humber one of the Wilson liners, the Kelso, grounded on a sand bank near the entrance to the docks and broke her back. The sand banks in the Humber have lately been the cause of considerable anxiety to the authorities. The Edinburgh guardship has recently had to be moved to a fresh berth, as in swinging round she touched a newly-formed sand bank, and narrowly escaped what might have been serious injury. It has also been ascertained that a sand bank has been formed across the entrance to the Saint Andrew's Dock, which is visible at low water or spring tides. It is difficult to say to what this shoaling is due, but it probably arises from the small quantity of fresh water which has come down the river during the past few years. The sand banks in the Humber are notorious for their shifting and dangerous character, and there can be no doubt that the channel could be greatly improved by regulating its width by training walls, as has been done in the Ouse. The Conservancy Board obtained parliamentary powers to carry out works of this description a few years ago, on lines approved by the late Sir John Coode, but very little as yet appears to have been done.

In the Ouse the steamer Lennard, with 600 tons of coal with which she had been loaded in Goole Dock, when about a mile below the dock caught her stern on the ground, and the tide flowing up very strongly carried her bow on to the stone training walls, when she listed over 70 deg. This case unfortunately was attended with loss of life, the second engineer and fireman being unable to escape from below, were drowned. Owing to the strong current running in the river, and the position in which the vessel was laid, considerable difficulty was been found in effecting her removal. A short time after this disaster a train of seventy compartment barges, locally known as "Tom Puddings," each containing about 40 tons of coal which had come into Goole Docks for shipment, was sunk. The accident was due to one of the barges sinking from a leak and dragging the others down with it. At Grimsby the s.s. Kent collided with the steam trawler Regina as she was about to enter the fish dock with a cargo of fish. The trawler sunk within a few minutes. At Boston the s. steamer Ethel of Newcastle with a cargo of about 1200 tons of iron ore from Bilbao, in passing round a bend in the river, a short distance below the dock, ran into the training wall, and her stern being carried by the next tide across the river, the channel was completely blocked. As the tide fell the fore-and-aft ends grounded, leaving the vessel unsupported amidships. Consequently the side plates forward of the engine-room bulkhead buckled, and left an opening 2½ft. wide, the break extending across the deck and down each side below the low-water line. The vessel thus became a wreck, stranded across the bed of the river, the water at high tide coming completely over her decks. This accident was due to the pilot bringing the vessel up too late on the tide and not taking proper precautions when passing round the head. The harbour authorities at once took possession of the vessel and put themselves in communication with several firms of salvors and wreck raisers. From one of these an offer was received to remove the vessel out of the channel for £2000, when the cargo was removed. This offer not being accepted, the commissioners instructed their engineer to take the matter in hand. As similar disasters occasionally occur in other rivers, an account of the method adopted for raising this vessel, as given in the local newspaper, may be useful. About 800 tons of the cargo were removed, the remainder being under water at low water; the forepart of the vessel was prevented from breaking off from the afterpart by wire ropes carried to the afterpart over a bridge of timber constructed in the centre. A platform deck was constructed half way up the forehold above the level of low water, and a vertical bulkhead clear of the breach, the whole being caulked and made water-tight. This deck was well strutted to the upper deck and framing of the vessel. Two heavy baulks of timber were laid across the deck of the vessel, and from these chains carried under the bottom and drawn up tight by screw bolts. In the lower part of the hold about 500 empty petroleum barrels were placed. The engine-room was pumped out by means of an ejector and pulsometer supplied with steam from two boilers placed on deck for the purpose. Access was then obtained to the donkey engines and bilge pumps belonging to the vessel, and the water was pumped out of the engine-room and after hold. Wooden wedges were driven into the openings between the plates where they had bulged and weighted sail cloths dropped over the breach to keep as much water out as possible. When these preparations were complete, as the tide rose sufficiently to float the vessel, she was drawn by chains carried to the shore on to a berth which had been dug away for the purpose at the side of the river and out of the channel. By working both day and night tides the whole was accomplished in a week from the time the order was given for removal, at a cost of less than £500, the channel having only been closed during one set of neap tides.

## BELGIAN STATE RAILWAYS.—BRAKE VAN FOR GOODS TRAINS.

The brake van illustrated on page 256 has just been brought out by M. Leon Bika, M. Inst. Mech. Engineers, Chief Engineer, and Inspector General of the Belgian State Railways. It is not intended to be used for passenger traffic, but is meant for merchandise, and more particularly for coal and mineral trains.

A brake van for a train of this description should be heavy, strong, and cheap both in construction and maintenance. As a light wagon has not sufficient adhesion for a heavy mineral train, additional weight is often given by the insertion of flat plates of cast iron between the floors, and if a collision takes place these plates frequently make the disaster worse by forcing their way through the wooden sides. M. Bika also uses cast iron plates, but makes the lower floor of them, thus securing weight and rigidity. Three castings are used, of which two are off the same pattern; the middle one being necessarily longer, as it must project on either side of the others to leave room for the look-out windows. They are cast from a common quality of pig iron, and are simply bolted together. Holes are cast in them to receive the rails which form the frame. These rails are old ones, and are used just as they have been taken up. In the front and back part of the vehicle, a rail of the current length, 20ft., is used, so that it only needs bending, no cutting being required. Iron plates of a common quality, but $\frac{5}{16}$in. thick, are rivetted to these rails and along the bottom to a ridge on the castings, and the rails are also run into the latter with iron cement. The system of employing cast iron plates for the floors of railway wagons has been in use for the last thirty years on the inclined planes at Liége. It not only renders the wagon very stiff, but it simplifies the construction by doing away with the longitudinal and cross girders, the bracing, gusset plates, &c.

M. Bika considers rigidity of even greater importance than weight. A brake van is more costly than an ordinary truck, and it always contains human beings, whose safety should be studied; and yet in many mineral trains the brake van is the weakest part of the train, and most likely to suffer from telescoping if there is a collision, or to be crushed if overturned on an embankment. In M. Bika's system the brake van is less likely to suffer than the rest of the train, whilst if damaged it is not expensive to repair. Even if there should be a collision of sufficient violence to force in either of the end walls of the car, the men, being in the central portion, would probably not be injured by it.

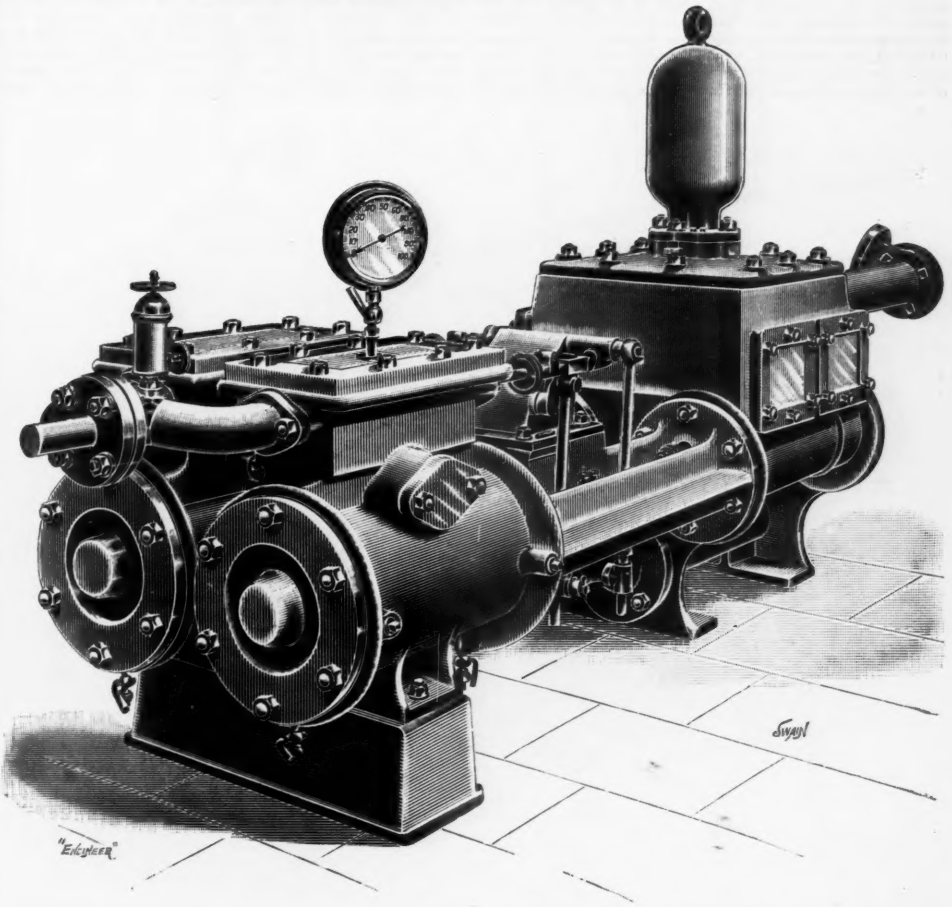
The method of suspension is new in brake vans. The two springs are connected by a balance beam, supported in the middle like the beam of a pair of scales; so that the suspension practically takes place from three points. Besides adopting this method of increasing the stability, the wooden floor of the central compartment, reserved for the brake man, is not connected with the rest of the flooring on either side, but is carried on spiral springs which rest on the cast frame. The interior of the car is lined with match-boarding, an air space being left between the iron and wooden walls. As will be seen on the drawing, there are ventilators in the roof, which communicate with the air-space, whilst inlets have been made through the inner wall near the bottom, so that when the ventilators are open there is always a circulation of air, keeping the inside of the carriage cool, even when the exterior sheet iron is heated by exposure to the sun. When required, the ventilators can be immediately closed, so that there is no need to have them open in the winter.

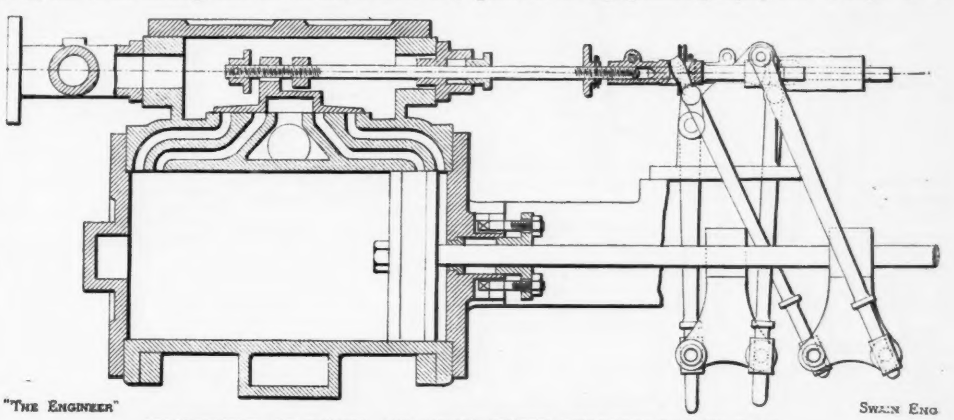
The extreme length of the carriage over the buffers is 21ft. 11in., and the extreme width 9ft. 10in. In the interior, after allowing for the space occupied by the double wall, the central compartment is 8ft. 10in. by 3ft. 8in., and those at either end 6ft. 2in. by 4ft. 10in. The internal height in the middle is 6ft. 5in. The weight is 21 tons. As it is intended to be used for very heavy trains, requiring a powerful brake, the van has intentionally been kept heavy.

In order not to have to introduce new types of wheels, &c., whilst those in use on ordinary brake vans would be too light for one of this weight, the horn plates, springs, axles, wheels, grease boxes, and brake-gear complete, are all those in use on the tenders of the Belgian State Railway. A mistake has been made both in the drawing and in the first van which has been constructed from it, and is now being exhibited at the Antwerp Exhibition. As the doors do not add to the strength of the vehicle to resist crushing, and should be as light as possible, they ought to have been made of wood instead of iron. This will be altered in all others that are made. The part reserved for the men is fitted up very comfortably, and there are many countries besides Belgium where M. Bika's brake van would be most useful.

THE PROSPECT DUPLEX PUMP

MESSRS. COLE, MARCHENT, AND MORLEY, BRADFORD, ENGINEERS





ARRANGEMENT OF VALVES AND VALVE LEVERS, PROSPECT DUPLEX PUMP

## THE PROSPECT DUPLEX PUMP.

In our reports of the machinery exhibited at the Royal Agricultural Show at Cambridge, reference was made to the "Prospect" duplex steam pumps, one of which we illustrate by the accompanying engraving. Both the pumps exhibited had steam cylinders 7in. diameter with 15in. stroke, but one had a 4in. and the other a 6in. pump. Our engraving shows the 6in. pump. The smaller pump is suitable for fire purposes and for high-pressure pumping, and the larger one for irrigation and low service pumping. The makers, Messrs. Cole, Marchent, and Morley, of Bradford, claim for this pump that it is the only general service duplex steam pump in the market which will work expansively, and they send us diagrams taken from a 7in. by 4in. by 15in. pump, which show that they can work expansively, and can vary the expansion in the cylinder, one diagram giving the greatest expansion, and the other a full stroke admission. One diagram was taken at a speed of 160 double strokes per minute, or 400ft. a minute each side. Another diagram, taken at four double strokes per minute, shows that with the same pump the expansion may be adjusted to suit the loads. As regards the water pumped, Messrs. Cole, Marchent, and Morley mention that with a 6in. by 4in. by 6in., and at a piston speed of 220ft. per minute, they have pumped 12,420 gallons in the hour, against a water pressure on the delivery of 4 lb., and a vacuum on the suction of 11in.; the theoretical capacity of the pump was 14,400 gallons, making an efficiency of 86 per cent.

## GLASGOW WEIRS.

THE recent passage through both Houses of Parliament of a Bill enabling the city of Glasgow to construct a weir with movable sluices across the river Clyde at Glasgow Green, calls attention, not only to the work about to be carried out, but also to the attempts which have been made from time to time to grapple with a difficulty which has for more than 100 years confronted the authorities of the commercial capital of Scotland. Apart from the great local interest involved, the history of the weirs of Glasgow carries with it a far more widespread importance in its general aspect as to the engineering difficulties involved in the management of an important tidal river, on whose successful control the welfare of a large industrial city in great measure depends. When it is stated that, in the comparatively brief space of a century, no less than three weirs have been erected across the Clyde within the "ancient royalty" of Glasgow in separate positions and have been removed, and that a fourth weir is about to be commenced, it will be readily understood that no little engineering skill and forethought have been exercised to place the regulation of the Clyde on a sound and satisfactory basis.

*Longitudinal section of River on line B.C.*

SITE OF FOOTBRIDGE AND SLUICES AND SECTION OF RIVER

Turning now to consider the different weirs which form the subject of this notice, the earliest weir across the Clyde would appear to have been built about the year 1772, as the following extract from a memorial for the trustees of the Clyde Navigation sets forth:—

"The weir . . . . . had its origin in the magistrates and Council of Glasgow, as then the only trustees on both the Clyde Navigation and on the bridges at Glasgow over the Clyde, situated above the harbour of the Broomielaw, having, in their capacity of Clyde Trustees, about the year 1772 caused a number of large stones to be thrown into the river around the piers of the Jamaica-street Bridge, now called the 'Glasgow Bridge,' in order to strengthen the piers of that bridge, which had shown certain symptoms of instability, arising chiefly from the deepening that had for some time previously been made of the river and harbour by the Clyde Trustees immediately below or to the west of the bridge."

As far back as 1781 John Golborne, in a report dated September 7th of that year, relative to the improvement of the Clyde, gave it as his opinion to the magistrates of Glasgow "that the fall through the new bridge ought to be taken away, by cutting down the piles and removing the other obstructions in the three largest arches."

Nothing, however, was done, and the next mention of the first weir is to be found in "A Report by John Rennie, Esq., respecting Obstructions in the River Clyde, near the New Bridge," in which the following interesting passage occurs, which the experience of nearly a century has abundantly verified:—"The second material obstruction is the dyke or weir which has been built across the river, just below the new bridge, to preserve its foundations, the bottom of the navigation below the said dam and along the wharf at the Broomielaw being lower, as I am informed, than the foundations of the piers of the bridge. If therefore this dyke or weir was to be taken entirely away, the stability of the bridge would be endangered. I cannot help expressing my surprise that the foundations were not laid deeper in the original construction of the bridge. . . . . . The weir cannot now be taken away, but as I am informed it is in very bad repair, perhaps it may in rebuilding be so lowered as to afford a considerable addition of section to assist in carrying off the floods, and whenever it is rebuilt it ought to be done on a more permanent construction than it is at present."

The above report bears date August 22nd, 1799. Some eight years later, that is to say, in 1807, Rennie again refers to the weir, and advocates the building of a new one "across the river below the new bridge, and 1ft. lower at its top than the present one." The next point of interest in the history of the first weir was the passing of the Act of 1829, Section II. of which authorised the Bridge Trustees in taking down the old bridge to remove the weir. Section VI. of the same Act required the Clyde Trustees to contribute from the river and harbour duties the sum of £6000, in three instalments, for the "great benefit that would result to the Harbour of Glasgow and the navigation of the river Clyde from the removal of the weir below the bridge, opposite to Jamaica-street, and from sinking the foundations of the piers of the proposed new bridge below the level of the harbour at the Broomielaw as now deepened."

SECTION ON LINE OF PROPOSED FOOTBRIDGE

In 1836 Mr. Walker, in his report to the Parliamentary Trustees for improving the navigation of the river Clyde and enlarging the Harbour of Glasgow, stated "power to open the river above the Broomielaw for navigation is proposed to be applied for. To effect this the weir below the new bridge must be lowered, and the depth of the foundations is such that it can be done without danger to that handsome structure—the last work of Telford. The removal of this weir, and the deepening above it that will be the consequence, will form another important addition to the reservoir for tidal water, as every tide will ebb several feet lower than it does at present."

WIER AND LOCK REMOVED 1879-80

Some four years later, viz., in 1840, the Clyde Trustees applied to Parliament for powers to further deepen and improve the river, and the plans deposited with reference to this Bill *inter alia* represented the removal of the Glasgow Bridge or first weir. Prior, however, to the passing of the Act of 1840, questions had depended before the Court of Session between the water companies, the Clyde and Bridge Trustees, and the authorities of Rutherglen, in relation to the then state and condition of, and the legal rights of parties in reference to the weir. Finally, in 1842, the weir was removed to the under side of Old Stockwell-street Bridge. The second, or Stockwell-street Bridge weir, was not, however, destined to last long, for as early as 1844 Mr. Walker, in reporting to the Committee of Management of the Bridge Trustees of Glasgow, advocated the removal of the weir to a point higher up the river, in order to maintain a sufficiency of water for the water company at this part. In 1845 the rebuilding of the Stockwell-street, or Victoria Bridge, as it became designated, was rendered imperative by the disrepair into which it had fallen, and a Bill was introduced into Parliament to obtain the necessary powers, and as the removal of the old bridge rendered it necessary at the same time to remove the weir, powers were also sought to construct the weir still further up the river, and to place it about 140 yards above the Hutchesontown Bridge, which spanned the Clyde at the foot of the Saltmarket, where the Albert Bridge now stands, the Hutchesontown Bridge having been demolished in 1879. Accordingly, the Act 8 and 9 Victoria cap. 133 (1845) was passed, authorising, by Section 12, the removal of the weir from the Victoria to the Hutchesontown Bridge, and the construction of a lock in its vicinity, the cost of the removal and of the new weir and lock being borne by the Clyde Trustees as connected with and for the improvement of the navigation of the river.

In 1851 the third and last weir was built on the east side of Hutchesontown Bridge, being about 120 yards above that structure—the late Mr. James Walker, of London, acting as engineer both for the weir and for the new Victoria Bridge, which occupied the site of and replaced the Hutchesontown Bridge. The third weir, which was provided with a lock for the passage of barges, consisted of regularly-built masonwork, with rows of sheeting piles on the upper and lower sides. The height of its crest was about 2ft. below average high water of spring tides, or 11ft. below the surface of the coping of the South Quay wall. When unaffected by floods, the surface level of the water passing over the weir was 6ft. 4in. above the average low-water level at the underside of the Hutchesontown Bridge, and 7ft. 11in. above the average low water of the lower harbour, the depth of river water passing over the coping of weir being then about 11in. The lock was 74½ft. long and 25ft. wide, with a double pair of gates, having a depth of 8ft. on the upper sill, and 12ft. on the lower, at high water of average springs. The weir was a tumbling one, and was constructed throughout of solid masonry, the Clyde Trustees contributing upwards of £19,000 towards the sinking of the piers of the bridge and the removal and reconstruction of the weir—the weir and lock alone costing about £65,000.

In 1865 Messrs. James Leslie and Andrew Duncan presented their report on "The Proposed Removal of the Weir at the Hutchesontown Bridge," and "the effect which the removal of the weir may have on the navigation of the river both lower and upper, with the change that may ensue in the upper reaches of the river," in which, after dealing very fully with the data available, they say: "Were the weir removed the floods would doubtless not rise to so high a level as they do now, as the water would be more quickly run off, but the sandy and unprotected river banks which are now suffering seriously in many places from the action of the river, and are much in need of protection, would be liable to be still more acted on by the river, when under the condition of a lowered and consequently contracted channel and an increased velocity, and would therefore stand still more in need of protection than now, while the existing protection would in a great measure become inoperative." The third weir was not, however, destined to remain undisturbed: it formed for several years a topic of fierce contention, both parties—the one advocating its removal, the other its retention—straining every nerve to carry their point. Eventually the advocates for demolition gained the day, and in 1879-80 the third and last weir disappeared. Many reasons had led up to this final end. Amongst others it may be stated that the stability of the weir had become year after year more insecure, and the responsibilities which might have followed its failure while under their charge as maintainers of it being fully appreciated by the Clyde Trustees. In order to rid themselves of such responsibilities that body succeeded in getting Parliament to pass Section XXXII. of their Act of 1873, placing the burden and responsibility of the weir's maintenance and removal on the Water Commissioners after July 7th, 1878. Accordingly, on completion of the works in connection with the conduit under the Clyde by the Water Commissioners, the Clyde Trustees, acting as servants of the Commissioners, removed the weir and lock, and their accounts for the period between July 1st, 1879, and June 30th, 1881, show that they expended £527 2s. 7d. in so doing, while in their accounts for the year ending June, 1884, the following item appears:—"Removal of weir—Water Commissioners, £5000; less amount received, £225; total, £4775."

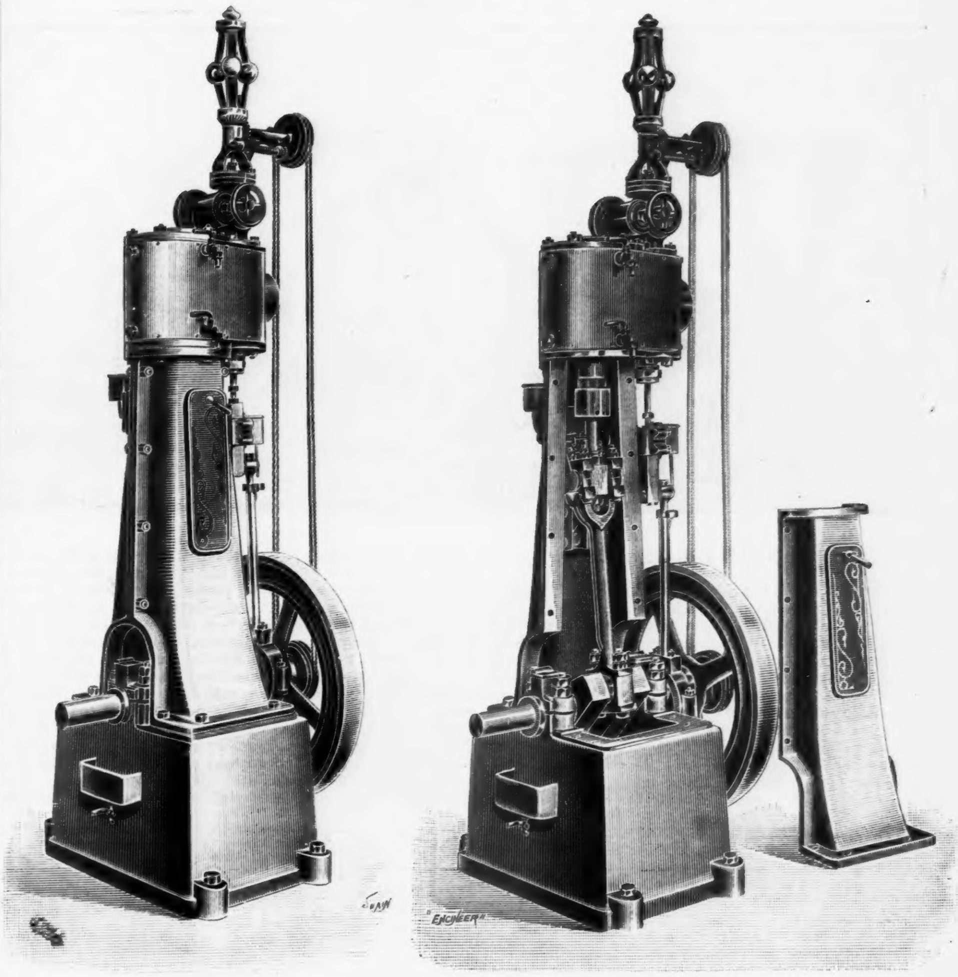
Turning now to consider the effects of the removal of the third weir, no better generalisation can be given than by quoting the words of Mr. James Deas, engineer to the Clyde Trustees, who characterises the demolition as "an unmitigated evil," and goes on to add that as regards the river above the site of the weir, the demolition "has led to the giving way of the banks as far as tidal influence extends, and has already entailed heavy expenditure, probably amounting to £10,000, on the riparian proprietors in the restoration of their banks and the preservation of adjoining property, and has injured the former amenity of the river by carrying up in great volume sewage discharged below the site of the weir, and which the weir formerly prevented ascending. Now immediately after the turn of the tide, the sewage can be traced by its discoloration of the water flowing upwards as far as the tide will carry it, while at low water the bed of the river exposed to view is revealed in all its slimy hideousness. Previous to the removal of the weir there was at all times a stretch several miles in length of slow-flowing river never varying more than a foot or two in level, except when the river was in flood, largely used, especially by the working classes for boating, carried on at all times of the tide throughout the whole day, and in summer evenings crowded with rowing craft. This valuable pastime has been reduced to at least a-half by being made entirely dependent on the tidal ebb and flow."

Whilst in regard to the navigation the same authority states that "the immediate effect of the removal was to bring down hundreds of thousands of tons of material from the bed and banks above the site of the weir, and which the weir kept from moving. During the first four years after the removal of the weir, 1,280,000 cubic yards of deposit required to be dredged out of the harbour and conveyed to Loch Long to retain the former depth of water in the harbour, against 786,000 cubic yards in the previous four years; whilst deep-draughted vessels are kept from half-an-hour to an hour longer waiting on the tide before they can leave, in consequence of the tide, which was formerly impounded by the weir, now flowing unimpeded into the upper reaches of the river. This delay is equivalent to at least a foot of loss of depth all the way to Greenock, vessels being now that time later on the tide of reaching deep water." The rapid erosion of the banks forced on the Improvement Trustees, as owners of property on the river side, an expenditure of no less than £3000 for sheet piling to protect the banks at Oatlands, while both the Suspension Bridge and the Humane Society's house adjoining became endangered by the excessive scour, and had to be upheld by works executed by the Corporation.

In consequence of the rapid destruction of the banks, the Corporation of Glasgow sought and obtained parliamentary powers to lay out a sum of £50,000 in repairing and strengthening the foreshores of the Clyde along the entire extent of the municipal boundaries. A special committee inquired into the whole question, and the late Mr. Carrick, City Architect of Glasgow, spent much time in considering the matter. It is not unlikely, had such a suggestion been practicable, that proposals would have been made at this juncture to replace the weir demolished in 1879-80; but the unwillingness of Parliament to sanction the placing of fixed dams across other tidal and navigable streams indicated the futility of endeavouring to obtain the necessary powers. About this time—1890—the attention of the Corporation of Glasgow was drawn to the action being taked by the Conservators of the river Thames who found themselves confronted by difficulties very similar to those which were being encountered on the Clyde.

HIGH-SPEED CLOSED ENGINE

MESSRS. CHARLESWORTH AND CO., OLDHAM, ENGINEERS



The Thames Conservators were endeavouring to solve the problem by placing a weir with movable sluices across their river at Richmond, and succeeded after a prolonged and exhaustive inquiry in securing the necessary parliamentary sanction, and commenced operations. In view of the interest taken in the Richmond weir, a special committee from the Glasgow Town Council and a deputation from the Clyde Trustees visited the Thames, whilst another joint deputation examined similar sluices on the Manchester Ship Canal, designed to control the flood waters of the river Irwell and to regulate the effluence of the river Weaver, where it unites with the canal and the Mersey below Runcorn. So satisfactory were the reports of the committees in each case, that it was decided to employ analogous means on the Clyde for dealing with similar difficulties—a resolution which has been materially strengthened and justified by the successful inauguration of the Richmond weir by H.R.H. the Duke of York, and by the eminently satisfactory manner in which the sluices have acted.

The new weir for which Glasgow has obtained parliamentary sanction will resemble in appearance an ordinary arch bridge of three spans, the clear opening of each being 80ft., and the headway 18ft. above ordinary high-water level at the centre of each arch. No lock will be provided, the river traffic, which is trifling, passing beneath the sluices, which will be raised altogether out of the water at high tide. The parliamentary estimate for the weir is £45,000, a portion of which will be furnished by the moneys provided for in the River Embankments Act of 1890, of which some £30,000 remains unexpended, and a portion by the Clyde Trustees, who propose to pay £2500 before erection "on being satisfied that the interests of the navigation of the river are likely to be benefited by the erection of the weir or tidal dam," and if they are after its erection that the interests of the navigation of the river have been thereby benefited, then not less than £2500, viz., in all a total contribution of £5000. In this connection it may be recalled that the Clyde Trustees paid £5000 towards the removal of the third weir in 1879-80, and that estimates have placed the total loss incurred through such demolition, by increased dredging necessitated and damage sustained from augmented scour, at no less than £200,000.

Turning now, in conclusion, to the proposed weir, the sluices are designed by Mr. Francis G. M. Stoney, M.I.C.E., whose experience in designing and carrying out similar works is well known, both at Richmond—on the Manchester Ship Canal—on the river Rhone near Geneva, and on the Nile; whilst in Ireland flood sluices were executed on the river Suck and at Belleek, and controlling sluices on the river Shannon, at Lough Allen, and on the Lough Erne drainage works. For the Clyde weir movable sluices are designed in such a manner as to impound the upper waters at a level of 3ft. below high water, whilst mechanism is provided which, so soon as the flood tide raises the lower water to that level, lifts the sluices out of the river, leaving the whole waterway free for navigation. The same appliances lower the sluices when the ebb tide subsides to the level of the impounded water. A wooden float is secured to the top of each sluice, and gives it sufficient automatic buoyancy to allow flood water to pass below independently of the arrangements for dealing with the tidal water. The sluices are provided with counterbalance weights, and are accordingly very easily controlled.

The engineer of the proposed new weir is Mr. Alexander Beith Macdonald, M.I.C.E., city engineer of Glasgow, whose courtesy has placed at our disposal the views we reproduce from the model of the new sluices, and afforded us much information of a valuable nature in dealing with the fourth weir Glasgow is about to erect across her famous river.

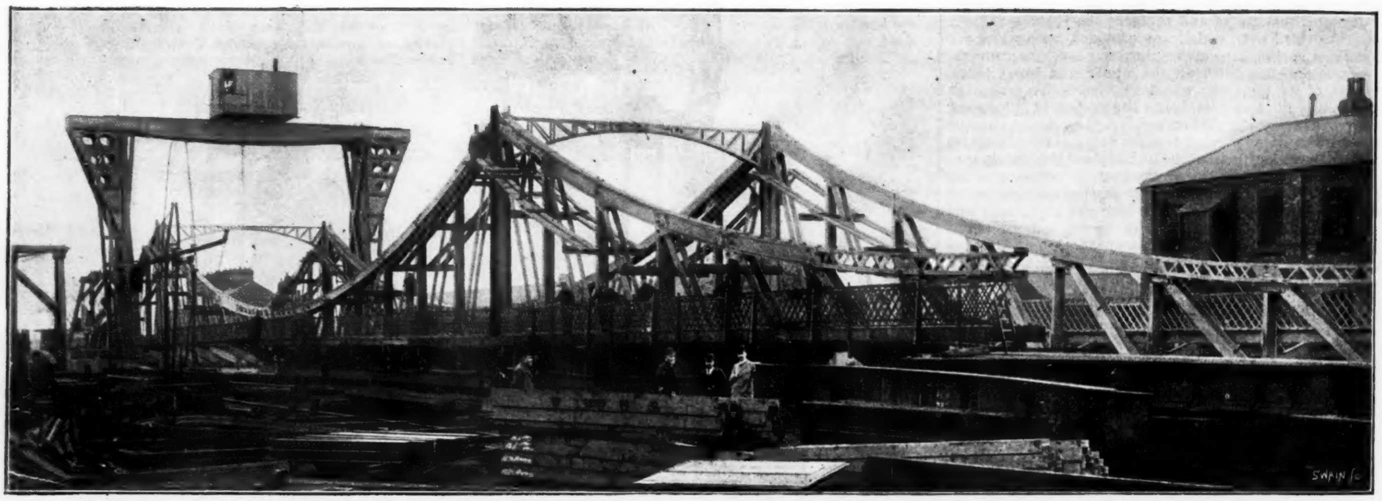
## HIGH SPEED ENGINE.

We illustrate a rather novel high speed engine, which is one of a series recently introduced and manufactured by Messrs. S. Charlesworth and Co., Oldham. It is a double-acting, and of the enclosed type, and is specially designed for driving high speed machinery direct or by belt, or is fitted with a dynamo on one bed-plate for ship and other work. The novelty in design is as seen from the illustrations, the enclosed case being made in two halves, bolted together. The guides and cylinder are permanently carried by the back half. The front half is readily and quickly taken away, and the crank or any other part accessible and removable, thus combining—the makers' claim—the advantages of an enclosed and open type engine. For all ordinary purposes, such as packing the gland and inspecting the crosshead, a door is provided. All parts of the engine are automatically oiled. The strength of the parts has been proportioned for very high boiler pressures. The steel crosshead is easily taken out for examination, and like the other parts has large wearing surfaces. The engine illustrated has a 7in. cylinder, 6in. stroke, 10 brake horse-power, at 350 revolutions, at 60 lb. boiler pressure. It is fitted with a Pickering governor, but is also made with an automatic centrifugal governor, and all the engines are fitted with piston valves.

**Skelton and Brotton Sewage Disposal.**—A Local Government Board inquiry was held on the 12th at the Local Board Offices, Skelton-in-Cleveland, by Mr. W. J. B. Clerke, M. Inst. C.E., engineering inspector. There was a large attendance, including representatives from the Saltburn Local Board, who some time ago obtained an injunction at the county court to prevent the Skelton and Brotton Local Board from polluting with sewage from their district the Skelton Beck, which flows through Saltburn. The inquiry was held to obtain the sanction of the Local Government Board to borrow £14,500 for works of sewerage and sewage disposal which will prevent this pollution. The scheme, which is of a complex and difficult nature, is from the designs of Mr. D. Balfour, M. Inst. C.E., F.G.S., of Newcastle on-Tyne, and comprises about ten miles of 21, 18, 15, 12, and 9in. sanitary and iron pipes, with manhole and lamphole shafts, flushing chambers, iron pipe valley crossings. The work consists of a combined intercepting scheme for conveying the whole of the sewage from the ten villages comprised in the Board's district to a point at the top of cliffs on the coast called Cranedale Spout, where the high cliffs, 200ft. in height, will be bored and lined with iron pipes, which will be jointed at the bottom with iron pipes having easy bends, laid in a heading, driven from the beach; and then by means of cast iron pipes laid in a cutting in the rock, of which the beach is composed, the sewage will be delivered at lowest point of the furthest ebbing tide. The scheme was explained and other evidence given by Mr. D. Balfour, jun., A.M. Inst. C.E., on behalf of the engineer, after which the inspector visited the whole of the district.

# ROAD BRIDGE FOR BRAZIL

MR. MAX AM ENDE, M. INST. C.E., ENGINEER; MESSRS. JOHN BIRCH AND CO., CONTRACTORS



## ROAD BRIDGE FOR BRAZIL.

This bridge, for which the contract was made with Messrs. John Birch and Co., London, and which is being erected by them over the Cachoeira River, is a steel structure, carrying a concrete roadway 32ft. 9½in. wide between the main girders, and two footpaths 4ft. wide outside of them. The length between abutments, 524ft. 1¾in., is divided into five spans, of which the central span is 197ft. 8¾in. between centres of piers. The main girders over the three middle spans, although they resemble a certain system of suspension bridges, are cantilevers, converted into continuous girders by inserting the central piece of the top flange after the completion of the bridge so far. The platform of the bridge is continuous between the abutments, and the structure is fixed only to the second pier, resting on rollers on the three other piers and on the abutments. At the first and fourth piers the continuity of the top flange is interrupted. In consequence of this arrangement the end spans do not affect the stresses in the main structure, except in so far as they furnish the necessary balance weight when the middle span is loaded; in consequence of the temporary omission of the central piece of the top flange, the central span without the live load is accurately balanced by the adjoining spans, and the stresses for this case are calculated in an elementary way. These are stated in the third column of the table of stresses, the figures in the first column identifying the parts in the diagram, Fig. 1. The stress in the top flange and the shearing stress at the centre are known to be nil.

When, however, the live load enters upon the bridge these two stresses are quantities not known, but calculable from the elastic change of form of the structure. In the present case of a road bridge where great irregularities in the live load do not occur, and where the greatest live load is only one-third of the total load, viz., 1½ ton per foot lineal, it was deemed sufficient to calculate only three cases of its distribution, viz., (1) upon the whole bridge, (2) upon the central span, and (3) upon the two adjoining spans. In each case the shearing stress in the centre is nil, and therefore only one unknown quantity, the stress in the central flange-piece, has to be reckoned with. But instead of this, the stress in any two symmetrically-placed pieces of the flanges, or the two equal balance weights, may be regarded as unknown quantities, and the latter have been chosen as the most convenient. If they did not exist, either in the positive or the negative sense, the stresses in the structure from the live load could be calculated in the elementary way for the three cases of distribution, and the ends would then be raised or lowered; but as they do exist, and as the ends are not free to rise or fall, the unknown balance weights enter into the calculation. The stress in any bar is therefore the sum of two stresses, viz., the one from the dead load and the other from the balance weights, both calculated in an elementary way. The second column in the table gives the extension of the bar from a stress of one ton per square inch $\frac{l}{Ef}$ (length divided by modulus of elasticity and sectional area). Multiplying this with the total stress, we obtain its positive or negative extension, and multiplying once more by the stress and dividing by 2, we obtain the work performed by the stress. Equilibrium prevails if the sum of the work in all bars is nil, and we have therefore an equation from which the balance weight can be calculated, and consequently the stress in each bar determined. The result for the three cases is stated in columns 4, 5, and 6 of the table. To each of these the third column would have to be added to give the total stress; but in the 7th column only those cases have been selected which give an absolute maximum. The process here described has already been referred to in these pages—vol. 64, page 200; vol. 67, page 399; vol. 75, page 429; and elsewhere—and further explanation can therefore here be dispensed with.

The live load has been assumed, as already stated, at 1½ tons per foot lineal, or 82 lb. per square foot. The dead load consists of 1·2 tons per foot lineal steel, and 2·0 tons roadway material. Assuming the footpaths to be made of a 4in. layer of a material weighing 140 lb. per cubic foot, a weight of 123 lb. per square foot of roadway material would remain, which is sufficient to make it optional whether the surface should be of granite or of wood blocks. The sectional dimensions of the steel parts of the structure are arranged so that the stress does not exceed on the square inch gross 5½ tons, or on the square inch net 6½ tons.

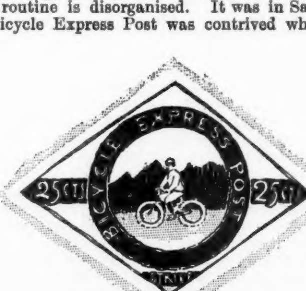
Fig. 2 is a half longitudinal section and a half elevation of the bridge. Figs. 3 and 4 are cross section and elevation at the main post, showing the rocker bearing. The greatest pressure upon this bearing is 465 tons; as there are seventeen rockers, 30in. long, the pressure per lineal inch is about 0·9 ton. The vertical pressure on the post from the flanges and diagonals is about 427 tons, transmitted partially direct in the planes of the diagonals and the vertical webs of the flanges, partially by way of the transverse flange plates and the cast steel saddle over which they are bent. In order to effect a simultaneous transmission of stresses both ways, the saddle is made adjustable by means of wedges as shown.

Fig. 5 is a cross section of the bridge at the second post, showing the construction of the platform. The plating under the roadway consists of flat plates and reversed troughs, the latter pressed in lengths of 9ft. 4¾in. Fig. 6 is an enlarged section of a trough. It is important that the troughs are made with horizontal flanges, as otherwise the horizontal shearing stress in the web, which produces the flange stress, would have to be taken by rivets in the web. In the present, as in most cases, the number of rivets required would be greater than is possible to place in a given length. The load concentrated upon one wheel is assumed at 5 tons, and the concrete is assumed to distribute that load across the flat plate upon two adjoining troughs. Such distribution by means of the concrete is always relied upon in the construction of roadway plating.

Fig. 7 shows the connection of the top flange of the cantilever with that of the cross girder by means of two angle bars and the roadway plates. The load on the central span does not entirely depend on the end spans for its balance weight, but there are anchorages in the first and fourth piers which are sufficient without the end spans. The total weight of metal in the bridge is 722 tons; of this 149 tons are in the roadway and footpath plating, and 68½ tons are cast iron. The bridge has been constructed at the works of the Cleveland Bridge and Engineering Company, under the inspection of the contractors' engineers, where it was temporarily erected as shown on illustration.

## A BICYCLE POSTAGE STAMP.

Here is a singular outcome of the recent railway strikes in America, interesting as showing the strange uses to which necessity can put mechanical inventions when the more ordinary routine is disorganised. It was in San Francisco that a Bicycle Express Post was contrived when railways were "hung up" and rolling stock belied its name, and rolled no longer. Stamps and envelopes were specially designed for this emergency, and were in use while the strike lasted. They are roughly lithographed, and are of only one denomination—25 cents. Already these stamps are being sought after, and command a premium extravagantly higher than their original value, and they will doubtless in time to come be almost the most precious of the stamp collectors' varied hordes.



**Naval Engineer Appointments.**—The following appointments have been made at the Admiralty:—Chief engineers: Frederick W. Wells, to the Fearless, undated; John L. Mitchell, to the Tartar, to date September 18th. Engineers: Edward A. E. Crowley, to the Humber, and W. G. Mogg, to the Curlew, to date September 25th; William H. Meadus, to the Firefly, and G. W. Murray, to the Bullfrog. Assistant Engineers: W. H. Crichton, to the Fearless, to date September 25th; James P. Leahy, to the Tartar, to date September 18th.

# LETTERS TO THE EDITOR.

*(We do not hold ourselves responsible for the opinions of our correspondents.)*

## THE THEORY OF THE STEAM ENGINE.

Sir,—The defect in Mr. Cherry's method of discussion is radical, and apparently permanent. I quite well remember what he has written before in your pages anent Dr. Lodge and others. That has nothing whatever to do with the question I raised. Mr. Cherry cannot manage to confine himself to the subject he ought to discuss. I very much doubt that he did more than glance at my letter; he certainly has not made himself acquainted with its contents. I said not one syllable about air near its critical point. With Dr. Lodge's statements, *ex cathedra* or otherwise, I am not at present concerned. What I did say is worth repeating, for Mr. Cherry possesses information enough to handle a subject very well, if only he can manage to stick to one thing at a time.

Permit me to repeat in other words what I have said. We very frequently find it stated that the efficiency of a steam engine is to be ascertained, like that of a hot air engine, by difference of temperature before and after a certain process has been performed. Dr. Lodge, in the case of the steam engine, takes, I understand, the furnace temperature for T and the condenser temperature for $t$; at least I put that construction on some of his utterances, but I admit that I may have failed to grasp his full meaning. Putting this on one side we find that in the hot-air engine we have $\frac{T - t}{T}$ as a measure of efficiency, and to the steam engine precisely the same formula is applied. Now what I said in my first letter was simply that this was all wrong. The basis of the formula is that if air expands without doing work it will not fall in temperature; if it does work it falls in temperature, therefore the fall is due to the doing of work, and the falls bears a definite relation to the amount of work done. Mr. Cherry drags into the discussion irrelevant matter concerning an infinitesimal augment of energy, and something about the condition of air near the critical point. The air in a hot-air engine is not near the critical point. Professor Dewar's results have nothing to say to the question I have raised. My proposition is that, when steam expands it falls in temperature whether it does work or not, and that consequently $\frac{T - t}{T}$ has no application to the steam engine either in theory or practice. To make my meaning clear I will take a numerical example.

A single-cylinder engine is working at an absolute initial pressure of 100 lb. on the square inch, and expands this steam five times. The pressure at the moment the exhaust port opens is a little less than 20 lb. I neglect all questions of cylinder condensation, &c. They have nothing to do with my contention. Now, the temperature of 100 lb. steam is 328 deg., and that of 20 lb. steam is 228 deg. If we write $T = 328 + 460$ and $t = 228 + 460$, we have $\frac{788 - 688}{788} = {\cdot}127$ nearly. But I say that these figures have nothing whatever to do with the work done by the steam. If the steam had expanded and done no work whatever, its initial and terminal temperatures would still have been 328 and 228 deg. Fah.

It is quite possible that Mr. Cherry will come in here and take me to task, if I omit to say that if the steam expands without doing work it will be slightly superheated. At all events, Rankine has said that probably it would be, because the heat required to make a pound of steam of 100 lb. pressure out of a pound of water at 32 deg. is 1181·4 units, and the heat required to make a pound of steam at 20 lb. out of a pound of water at 32 deg. is 1150·9, and the difference must be represented by something when the expansion has been effected. This is a mere trifle, however, and has nothing to do with my contention.

When steam is used to do work, the sensible heat is not converted into work at all; that continues to bear an unalterable relation to the pressure. What is commonly, and very erroneously called the latent heat, is in part converted into external work, with the result that a portion of the steam is liquefied. The actual work that one pound of 100 lb. steam can do in falling from 100 lb. to 20 lb. is given by D. K. Clark as 142,180 foot-pounds, and 184·2 units are expended in doing this work. Now, if the sensible heat of the steam was utilised, and if the specific heat of steam was the same as that of water, then it is clear that we must have a fall of temperature of 184·2 deg.; but, in fact, we have a fall of only 100 deg., although the specific heat of steam is only about half that of water.

The units converted come out of the latent heat of the steam. Steam of 20 lb. pressure has 953 deg. latent heat, and $\frac{953}{184} = 5{\cdot}18$ nearly, that is to say, about one-fifth of a pound of steam will be liquefied in doing the work, and the final pressure in the cylinder instead of being 20 lb. will be one-fifth less, or 16 lb. I am aware that these figures are not strictly accurate; to make them so I should have to resort to mathematics, which would in point of fact tend to obscure my argument. A discussion would probably arise as to what constant ought to be used with $p\,v$ and so on. Such things have nothing to do with my argument, which is that a comparison of efficiencies cannot properly be drawn between the steam engine and a hot-air or a gas engine, on the basis of the range of temperatures, sensible heat in the steam engine being only indirectly concerned in the performance of external work.

Range of temperature may be used to compare the efficiency of two *steam* engines in a rough and ready way, because the greater the range of expansion—other things being equal—the greater will be the efficiency; and the greater in expansion the greater the range of temperature. But this is quite another story.

September 15th. Maurice Cross.

## THE SOUTH WALES COLLIERS' SLIDING SCALE.

Sir,—The sliding scale dispute in South Wales concerns a very much larger public than the coalowners and colliers immediately interested. For fifteen years an almost automatic system of wages adjustment has been accepted and cordially supported alike by employers and employed in the coalfields of Glamorganshire and Monmouthshire. It may have operated disadvantageously on either side at times; but, notwithstanding the collision of feeling to-day, the coalowners and the colliers are in agreement that the sliding scale has preserved tranquillity in the whole of the South Wales and Monmouthshire districts; that, in conjunction with the Conciliation Board, it has kept the forces of capital and labour on harmonious lines; that it has given a measure of stability, unknown before 1879, to the quality of the output, to the profit of the turnover, and to the security of the interest of the money which all parts of the kingdom have been liberally and trustfully investing in South Wales colliery undertakings. Under the sliding scale shippers and merchants and the mining engineer have prosecuted these enterprises with a reasonable confidence in their forthcoming reward. The coal shipper made his contract without fear that a strike would impede its fulfilment; the coalowner could freely develope his "taking," on the assurance that wages disturbances were no longer likely to affect him; and the working collier was made a co-operative member—a profit sharer as also a loss sharer—in a great industrial organisation. This is in brief what the sliding scale agreement has done for South Wales and Monmouthshire, and now, by somebody's blunder, the very root of the scale, its concomitant Conciliation Board, and all the rest of the fabric built up so laboriously since 1879, appears to be in great danger of falling to pieces.

An old memory is not required for a reminiscence of the condition of things which existed in the Merthyr and Aberdare Valleys in the decade between 1865 and 1875. The time dates back a little before the Rhondda Valley began to send out its own store of the famous steam coal from its apparently exhaustless veins to all the ports of the world. Then and afterwards for another four years strikes were a constant incident of the coal-mining industry in the valleys.

There were strikes in this pit and in that pit; there were strikes in this valley and in that valley; there were strikes all over the place, more often than not of local scope and play, but once or twice during the years in question these great labour disturbances assumed a colossal and disastrous dimension. For one thing, the rate of wages differed in almost every pit in every valley. There was no union among the coalowners; still less was there a union among the colliers. There was a continual seismic disturbance among the men who troubled the earth underneath its crust, and the tremor reacted upon the coalowners, as well as on their agents in Cardiff, Newport, and Swansea. It was to find an equilibrium in these shifting sands that the South Wales and Monmouthshire Conciliation Board was established in 1879, and out of the loins of that institution came the historic, and for a long time exemplary, sliding scale agreement. The miners' wages, according to the original plan, were to rise or fall at the rate of 10 per cent. in the shilling on the upward or downward price of coal. There have been some modifications of the first arrangement, and wages now move up or down at the rate of 8¾ per cent. in the shilling per ton of coal. The colliers are now asking that the sliding scale should be re-established on the 10 per cent. basis, but that really is only a small point of detail in comparison with the graver circumstances which have brought about the present crisis. The colliers are this week voting on the question whether they shall give notice to terminate the sliding scale agreement in six months' time. The ballot is to end on the 24th inst., and already it is clear that a great majority are voting against the sliding scale in its existing form and constitution. The cause, or the ostensible cause, of the rupture is supposed to rest on the proceedings of the Conciliation Board at the last monthly meetings of the Joint Committee of the masters and the delegates of the men. It came to pass that the sliding scale auditors had to declare another small reduction of the colliers' wages, and that seems to have been accepted without comment and as a matter of course. But the colliers, through Mr. W. Abrahams, M.P.—"Mabon"—and his colleagues, wanted the coalowners to consent to a revision of the very much revised scale of 1879, chiefly in the sense of altering the incidence of the rise and fall of wages back again to 10 per cent. on the shilling, and to permit of the employment of an umpire in cases of dispute which the Board of Conciliation would not settle of its own accord. So far all would seem to have been fair sailing. The rock ahead appeared in the tribunal which has hitherto done so much excellent work as the Conciliation Board.

Sir W. T. Lewis and the coalowners' representatives declined to accept the evidence of the check weigher of an Abercarn colliery, as a witness to the custom and rates of payments in that particular pit. A small matter this, one would think, to throw 100,000 men into perturbation, and imperil the amicable arrangement which has stood the storm and stress of more than fifteen years of practical usage. It was, however, sufficient to cause a decided rupture between the colliers' delegates and the representative of the coalowners. Without delving for a more intelligible reason, one is constrained to admit that the two combatant parties seem to have found sufficient excuse for a quarrel which can only have the effect of injuring the interest both of them should seek to protect.

Cardiff, September 18th. N.

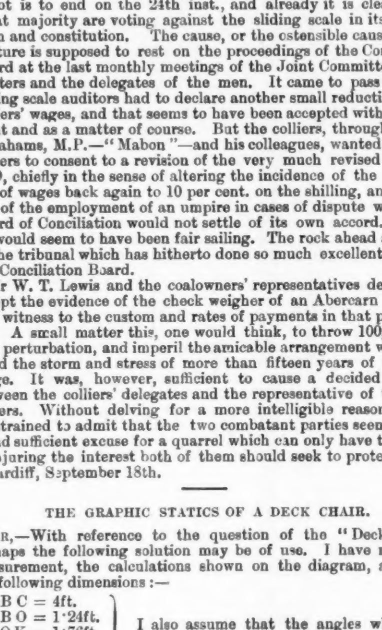
## THE GRAPHIC STATICS OF A DECK CHAIR.

Sir,—With reference to the question of the "Deck chair," perhaps the following solution may be of use. I have made, by measurement, the calculations shown on the diagram, assuming the following dimensions:—

B C = 4ft.
B O = 1·24ft.
O K = 1·76ft.
K A = 1ft.
D O = 1ft.
O E = 2·05ft.
E C = 1ft.

I also assume that the angles which the canvass makes with its supporting struts are as shown on the diagram. I have no measure of their dimension.

Produce sides of these angles till they meet at G. The vertical line passing through the centre of gravity of the body in the chair will pass through this point. Let it cut the base at S, in the proportion, in the present instance, of 65 to 95. The reactions R, R¹ will therefore be 95 and 65 respectively.



Resolve R perpendicular to and along B O, and the compression in B O is found = 54.

Taking moments of P and R¹ around O, we obtain the equivalent force Q acting at E = to 85.

Resolving Q along E O and E K, the tension in E O = 35, and the compression in E K = 99 are found.

Resolving G W along G A and G D, and re-resolving, will give the compression in A K = 218.

Find the component of E K acting along K A, and subtracting from 218, we obtain 188 as the compression in K O.

The compression in D O will be readily calculated as 165. And to sum—

lb.
Compression in B O = 54
" " O K = 188
" " A K = 218
" " D O = 165
" " K E = 99
Tension in O E = 35
Bending Moments at O { = 78 × 1·24
= 22 × 1
" " K = 25 × 1
" " E = 64 × 1

There is also a small direct compression in C E, which can be readily calculated. Friction has not been considered. One half the above quantities will be the strains in each of the frames of the chair.

C. L. S.

## WORK IN DYNAMOS.

Sir,—Will you permit me to direct attention to what seems to me to be a very curious aspect of dynamo work, and one to which no consideration has been given by those who write on the theory of the machine. Let me, however, in the first place, say that I am familiar with the construction and working of dynamos for lighting purposes, so that I am not ignorant of the subject on which I write.

The resistance to the rotation of an armature is due to what has for convenience been termed "torque." This torque is due, of course, to the action and reaction of the field magnet and the armature on each other. The action and its reaction are precisely equal and opposite.

Now it appears to me that to all intents and purposes we may consider that it makes not the least difference whether the armature revolves while the field is at rest, or the field revolves while the armature stands still, and we may have the field running in one direction and the armature in the other at the same time.

The point which I want to raise is this. In an ordinary series-wound machine, let us say, what represents the loss of energy expended by the field in resisting the rotation of the armature? Energy is expended by the engine. To all intents and purposes the whole of that may be regarded as reappearing in the current. The losses are due to heating, friction, air resistance, current resistance in the wire, &c. This current is passed round the field magnets; it does work on these magnets, and it also does work in resisting the revolution of the armature. Why does not this appear?

The only answer must be of course that the field does not do any work. But how is this to be reconciled with the fact that the field offers the resistance?

It may be said that because the field does not itself revolve no work is done; but if this is the true solution of the difficulty, we find that energy may be expended by a current without absorbing power. If, however, we change the arrangement and turn the dynamo into a motor, we find that although the field magnets are doing just the same duty as they did when the dynamo worked as a current producer, they now absorb a great deal of work, although they are not revolving. In either case the field simply produces torque. That is all the engine has to deal with; but the results as to power expenditure are entirely different. What is the explanation of all this, or does it admit of explanation?

Birmingham, September 18th. J. Wolcot.

## TECHNICAL EDUCATION.

Sir,—The latest "Science and Art Directory" seems very much the same old thing. A great deal is heard in these days about technical education. Why cannot the South Kensington Department be made a more efficient instrument in the spread of such instruction? A notion prevails that technical education is essentially a matter of setting up workshops in connection with our public elementary schools, wherein boys are trained in the manipulation of tools. Establishments of the kind are doubtless most needful in great industrial centres. But after all, is that the best way to further the end in view? The general technical instruction of the artisan population is quite unnecessary. The average working man was never less in need of technical education than to-day.

Division of labour is simplification of labour. Take the engineering line: therein the range of work of each man is now restricted to the very narrowest possible compass; instead of the all-round mechanic we have the erector, the fitter, the turner, and the machinist. At the same time the skill, responsibility, and brainwork are centred into one department—the drawing-office. And similarly, in other industrial pursuits, few are those requiring technical knowledge. For such, however, a thoroughly good system of evening classes, in which the sound, common-sense, scientific principles of the chief industrial arts are taught, not by amateurs, smatterers, and crammers, but by practical men, would be useful.

Now the Science and Art Department does not meet the want—it goes from bad to worse. Much misconception is abroad regarding the value of science. As an instance, a writer to your journal recently informed us that "machinery is no more scientific than blankets or tea." The extravagance of the statement renders refutation unnecessary. Manual workers and many others engaged in engineering may not find it necessary to trouble their heads about scientific principles—they are not required to do so, but the draughtsman certainly is. True, very much is gained from experience and trial, and such must ever be the case to a very considerable extent, inasmuch as the acquisition of scientific knowledge is necessarily most limited. But the results derived from practice are often not forthcoming from science, because engineers despise the latter, and will not go thoroughly into it. Too familar acquaintance with the workings of nature—and science is nothing more—one cannot have; it is the lack, and not the abundance, of which makes essential that expensive substitute called practice.

Colchester, September 18th. Stephen Eddy.

## VALUES OF γ AND J.

Sir,—I shall feel obliged if you will allow me to correct two errors in my letter of last week. The two equations near the bottom of the fourth page should be

$$J\frac{dQ}{dv} = \frac{dE}{dv} + \frac{dW}{dv} \quad \ldots\ldots \quad (2)$$

$$J\frac{dQ}{dt} = \frac{dE}{dt} + \frac{dW}{dt} \quad \ldots\ldots \quad (3)$$

September 17th. William Donaldson.

# NEW SOUTH WALES RAILWAYS.

The report of the New South Wales Railways this year shows some very remarkable results, as will be seen from the annexed table prepared by Mr. Price Howell, of Lindfield, near Sydney. The table shows that the result of the year's working gives £61,552 net earnings in excess of all the other Australasian railways combined—Victoria excepted—with £13,046,377 less capital.

*New South Wales Railways.*

| | Year ending. | Gross earnings | Net earnings. | |
|---|---|---|---|---|
| | | £ | £ | |
| New South Wales | June, 1894 | 2,813,541 | 1,221,699 | |
| Victoria .. .. .. | " " | 2,720,000 | 1,070,000 | From Budget statement. |
| *South Australia | " 1893 | 1,022,727 | 370,901 | Latest information obtainable. |
| *Queensland .. | " 1894 | 931,053 | 332,650 | From Budget statement. |
| *West Australia .. | Dec., 1892 | 94,201 | 3,547 | Latest information obtainable. |
| *New Zealand .. | Mar., 1894 | 1,172,793 | 437,434 | |
| *Tasmania .. .. | Dec., 1893 | 152,083 | 15,615 | |

| *All other Government railways in Australasia combined excepting Victoria .. .. .. | 48,901,648 .. | 3,372,857 .. | 1,160,147 |

The Americans do it Better.—A correspondent of a South African paper writes to it as follows:—"Many of the English engineering firms are complaining of large amount of support given to American firms. It is not that the American machinery is better than English. The fact is the American firms do things better than the English. When they send good machinery here they send good men to erect it, and see it put on good foundations, whereas English machinery is left to the mercy of anybody to erect. I can name a place where a large English plant has been fixed by one wagonmaker, one sailor, one handyman, and one boilermaker's labourer. They have put a large air compressor on a rough stone foundation, wedged up with small pieces of iron. Such work is a disgrace to British manufacture." This is a flattering testimonial as to the methods of American manufacturers, and conveys a useful hint to them in their foreign trade.

## RAILWAY MATTERS.

Railway season tickets made of aluminium are said to have been introduced into America. They are of circular form, about the size of a crown piece, and bear an artistic engraving; mention of the period of validity, and a fac-simile of the subscriber's signature.

A train on the Iron Mountain Railroad was blown from the track by a cyclone near Charleston, Missouri, on the 12th inst. Two persons were killed, and twenty others injured. The whole train was, according to a Reuter telegram, overturned by the wind and hurled 20ft. down an embankment.

The Paris, Lyons, and Mediterranean Railway Company is now building three types of locomotives—the first series comprising forty compound engines; the second, sixty electric locomotives, each capable of drawing 800 tons at a speed of 24 kiloms. = 15 miles per hour; and the third, electric locomotives the motor for which is mounted on the rolling stock.

On Sunday evening a Great Northern special train, running from Batley to Wakefield, run off the line at Batley Carr. The engine, in leaving the rails, tore up the permanent way for a short distance, dragging with it one of the carriages, containing a number of people, and was overturned. About fourteen persons were injured. There is a sharp curve close to the spot where the accident occurred.

The directors of the West Highland Railway Company have resolved, as a consequence of the intended promotion by the Highland Railway Company of a line from Fort William to Inverness, contrary to the understanding arrived at during the progress before Parliament of the Bill for the West Highland Railway to Fort William, when the district between Fort William and Inverness was recognised as the district of the West Highland Company, to deposit a Bill in the next session of Parliament for the extension of the West Highland Line to Inverness.

The construction of the Waterloo and City Railway is peculiar in the respect that the staging in the river is the basis of the whole of the operations, the advantage of this being that there will be no openings on land, and therefore no property to acquire in the streets for carrying on the works, and no interruption to traffic. The tunnels will be of cast iron, 22ft. in diameter, where the line is straight and on easy curves, and 9in. wider on sharp curves, so as to allow the running round of the bogey carriages to be employed without fouling the sides. The precise form of the carriages has not been decided upon yet. It is anticipated that the journey from end to end will occupy four minutes.

The Great Eastern Railway Co. have agreed to lay down 1000 iron bark sleepers, and that the London, Brighton, and South Coast Railway Company have ordered 2000 red gum sleepers. The first 500 iron bark sleepers are about to be sent home, and others will be forwarded very shortly. The Government of New South Wales is making special concessions with a view to the introduction of the Colony's timbers into England. It is stated that this will be found far cheaper, besides immeasurably more durable than the soft woods now being used. The durability of hard wood sleepers is said to be three times greater than that of the soft wood used in England.

According to the British Vice-consul at Bourgas, although the Yamboli Bourgas Railway has not yet entered on an era of prosperity, last year a deficit was avoided, and measures are in contemplation for further increasing the usefulness of this line, but the heavy differential tariffs still prevailing on the Oriental Railway Company's line render completion difficult, if not impossible, and grain continues to be sent from the Radné, Maballé, and Nova Lagora districts to Dédéaghatch instead of to Bourgas, which latter appears to be its natural destination. But this ceases to excite astonishment when one learns that by a system of private bargains between the Oriental Railway Company and its customers a discount amounting occasionally to as much as 47½ per cent. is allowed on the carriage of corn from Yamboli to Dédéaghatch.

The number of casualties on Indian railways during last year decreased by 1·26 per cent. as regards killed, and 2·78 per cent. as regards injured, as compared with the two previous years. The proportion of passengers killed in train accidents from causes beyond their own control was 1 in 2,652,215, while that of passengers injured from this cause was 1 in 1,610,261. The chief increases in accidents were reported on the Southern Mahratta, Great Indian Peninsular, the Nizam's Guaranteed, and the Burma State Railways. The highest percentage of casualties to the train-mileage run is recorded against the Nizam's Guaranteed Railway, while the lowest was shown on the Morvi Railway. Taking the aggregate length of the whole Indian railway system as 18,121 miles, the train-mileage run as 2,088,759 miles, and the total number of passengers travelling as 135,269,950, there were 114 killed, and 268 injured, or an average of 1 killed in 1,186,517, and of 1 injured in 504,738.

The first train on the Nilgiri Railway was successfully run from Mettapollium over the Bowani Bridge and as far as Kullar, the foot of the ghaut, on the 26th July in the presence of the chief engineer and other officials of the Nilgiri and Madras Railways. The Bowani Bridge is one of the largest on the line, and has given a great deal of trouble owing to the sudden and unexpected floods to which the river is subject at all seasons of the year. The *Indian Engineer* says that it rose on one occasion as much as 14ft. in the month of February, a month in which, judging from all previous years, it should have been quite safe to work in. Work was in full swing at the time, and the results were most disastrous. Three portable engines and pumps, the cofferdam and all the temporary works were completely swept away. Mr. Weightman determined, on the advice of the consulting engineer, to alter the mode of construction and to place the foundations on wells. The sinking of these through the boulder bed of the river by divers was a tedious process, as it was constantly interrupted by floods. The whole bridge was completed for less than the estimate in about eighteen months at a cost of just over a lakh of rupees, and it reflects the greatest credit on Mr. D. J. Lavelle, the executive engineer in charge, and all concerned in its construction.

A correspondent writing to the *Times* on the subject of light railways says:—"I have travelled to-day in an international—so-called 'lightning'—express on one of the most important highways of traffic in Germany. For a considerable part of the distance the line was entirely unfenced, and I venture to say without fear of contradiction that the permanent way at certain points was in a condition more dilapidated than any English engineer would dare to allow on the most out-of-the-way branch of his company's system. Of course, no accident happened, and a heavy train timed at some thirty-two miles an hour kept time all right. In this instance, it may be that our German friends have gone too far in the direction of economy; but have we not gone immeasurably too far in the opposite direction? What would any reasonable person think of the intelligence of the Little Pedlington Highway Board if it specified for the paving of the village street with jarrah-wood blocks laid on a 6in. bed of concrete, because this is found in Piccadilly the most suitable material? Yet this is really what we in England do in railway matters. We insist that a railway by-road in Caithness or Cardigan shall be paved, lighted, and scavenged precisely like the railway high-roads from London to Leeds or Liverpool. And then we wonder that railway rates are high. The Little Pedlington farmer, if he was fool enough to vote for the jarrah blocks, would at least have the sense to expect to have to pay for them when the rate-collector next came round."

## NOTES AND MEMORANDA.

The deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 15·9 per 1000 of their aggregate population, which is estimated at 10,458,442 persons in the middle of this year.

The rainfall over the Thames Valley during the month of August shows an excess of nearly a quarter of an inch over the 25 years' average; the recorded fall at Oxford being 2 48in., and the mean for 25 years 2 24in. for the same month. The excess of rainfall over the averages for the months of June, July, and August amounts to 1·71in.

When reading from that part of his British Association address which refers to the periodic law generally known as Mendeléeff's, Lord Salisbury read from a separate slip of paper a paragraph which properly gave the credit to Newlands, the first discoverer of the law. Mendeléeff's discovery was first announced, but it was first discovered by Newlands.

According to some experiments on the assimilability of potash by the action of nitrates in poor siliceous soils, by M. P. Pichard, it appears that, in presence of nitrates, a part of the potash combined with silica is capable of being assimilated by various plants, and hence that it is necessary to determine the total potash present in soils as well as that portion eliminated by acids or aqua regia when estimating the agricultural value of soils.

While endeavouring to determine the density of melted magnesia, M. Henri Moissan arrived at the conclusion that the density of this substance increases with the temperature up to bright red. It is thus that by heating in his electric furnace some magnesia, which is irreducible by heat, M. Moissan has been able to vary the density from 3·193 to 3·654. This is all the more noteworthy as this substance affords the only example of such a variation.

In London 2569 births and 1241 deaths were registered. Allowing for increase of population, the births were 111 and the deaths 168 below the average. The annual death rate per 1000 from all causes was 14·9. During the four weeks ended on Saturday last the death rate averaged 14 7 per 1000, being 2 9 per 1000 below the mean rate in the corresponding periods of the ten years 1884-93. In Greater London 3372 births and 1598 deaths were registered, corresponding to annual rates of 29·6 and 14·0 per 1000 of the estimated population.

At a recent meeting of the American Association for the Advancement of Science, Major J. W. Powell, of the U.S. Geological Survey, read a paper on the water resources of the United States. He said that the ultimate development of the United States rested largely upon the most thorough utilisation of the water resources. This was conspicuously true of the vast arid and sub-humid regions extending from the great plains to the Pacific coast. There the almost boundless extent of fertile land could not be utilised for agriculture without the artificial application of water. In all cases, whether in arid or humid regions, the proper solution of the problem rested upon the correct knowledge of the distribution and fluctuation of the available water. This study had been begun by the United States Geological Survey, and was now being carried on. We might commend this to the Geological Departments of the Australias.

Dr. Mansfield Merriman delivered an address before Section D of the American Association for the Advancement of Science on "The Resistance of Materials under Impact." He pointed out that the science of the resistance of materials, as taught in text-books, and used in the daily practice of every engineer, was mainly that of static conditions where external force is resisted by internal stress. The question of resistance to the impact of falling bodies, likely to occur in machinery, on bridges, and to a certain degree also in buildings, is recognised as important, but it is seldom reduced to computation or made the occasion of careful experiment. Even the fundamental principles and laws regarding it seem often not clearly understood. Dr. Merriman's address was an attempt to set forth the present state of knowledge concerning impact, and to reconcile some of the apparent paradoxes that often arise in the discussion and application of its principles. Some of Young's remarks on this subject might be referred to.

M. de Fonvielle calls attention to one of Roger Bacon's essays, published in 1618, in which some of the possibilities of steam are vaguely foreshadowed, and aërial navigation is declared to be a thing of the future. *Nature* quotes from a translation which De Fonvielle has furnished, and reads like Mother Shipton's prophecies. "Instruments may be made for navigating without any men pulling the oars, with a single man governing, and going quicker than if they were full of pulling men. Wagons also can be made so that without any horse they should be moved with such a velocity that it is impossible to measure it. . . It is possible also to devise instruments for flying, such that a man being in the centre if revolving something by which artificial wings are made to beat the air in the fashion of the birds. . . . It is also possible to devise instruments which will permit persons to walk on the bottom of the sea. . . . All these things have been done in old times and in our times, except the instrument for flying, which I have not seen, and I have not known any man who saw it done."

Two methods for the study of currents in open circuits and of displacement currents in dielectrics and electrolytes, were recently described by M. de Nicolaïeff before the Paris Academy of Sciences. Discs or rings of dielectrics are, in the first method, supported by bifilar suspension between the two poles of an electro-magnet, so that the plane of the ring is at 45 deg. to the axis of the electro-magnet, and centrally situated between the poles. The difference in the displacements caused in constant and alternating fields of the same strength is due to a secondary field set up by displacement currents caused in alternating fields. Paraffin shows an augmentation of 12 per cent. for a period of 930 per minute, and 9 per cent. for 770 per minute. In the second method, displacement currents in the rings are caused by the iron in the magnet cores. The ring is suspended perpendicular to the axis of the cores; the polar faces are able to be brought nearer to or removed farther from the parallel faces of the ring. By this method, augmentations have been obtained of 15 per cent. for yellow wax, and 8·3 per cent. for paraffin. Electrolytes in annular glass tubes behave just like perfect dielectrics, sulphuric acid giving an augmentation of deviation of 15 per cent.

An Atlantic race is continually being run by the great passenger ships. A Reuter telegram from Queenstown, dated September 14th, says:—"The Atlantic eastern record has again been broken. The Cunard line steamer Lucania arrived off here at 3.47 this morning, having completed the voyage from New York in 5 days 8 hours 38 minutes, her average speed being 21·84 knots. The daily runs were 447, 512, 494, 514, 506, and 337 knots to Daunt's Rock Lightship. The weather experienced was fine, and the winds were moderate, prevailing south-east to south-west. This trip of the Lucania occupied exactly the same time as her western record; but the performance is a better one, as she covered 23 more knots, 2787 knots being the distance run on the western route, as compared with 2810 on the eastern." A Reuter telegram, dated New York, September 14th, says:—"The American line steamer New York a few weeks ago established a new record from Southampton to New York, and landed her passengers in New York on the sixth day after they left London; but she has now beaten this performance by two hours. She left Southampton last Saturday, and passed Fire Island at 2 p.m. to-day, which will enable her passengers to land in New York before 6 p.m."

## MISCELLANEA.

The Construction Board of the American Navy has decided to recommend the building of a submarine boat on the Holland type.

There is to be a new harbour at Rotterdam on the other side of the Maas, near the village of Katendrecht. The cost is estimated at £22,500.

The entrance to the fourth floating dock in Honfleur Harbour has been widened to 41ft. 4in. This port now admits at spring tides vessels drawing from 21ft. to 22ft.

The highest known flood at Lucknow occurred on the 13th inst., when a large portion of the city and of the civil station was inundated. Many houses in the suburbs were completely submerged, and the safety of the bridge was in doubt.

A Commission has been sent by the City of Bremen to England to study the arrangements at the harbours of London, Liverpool, and Manchester, in order that anything that appears worthy may be adopted in the free harbour that is about to be constructed at Bremen.

The scheme for cutting a canal from Marseilles to the river Rhone is again being discussed in the South of France. Its length would be thirty-four miles, and the average depth is proposed to be 10ft. for a portion of the way, and 6ft. 6in. for the remainder of the distance.

The Admiralty have issued a revised table of the working hours for men belonging to the Fleet and Dockyard Reserves. These have hitherto worked shorter hours than the dockyard men. The Reserve men are now given an eight hours day, or about forty-seven hours more each year than heretofore.

The South African Exhibition, which is to open at the Crystal Palace next May, will be classified under two main divisions, viz., (1) exports from South Africa, and (2) exports from the United Kingdom to South Africa. The subdivisions under these main headings will, roughly speaking, comprise raw materials, manufactures, mining and machinery, natural history and science, and the fine arts.

A series of lectures for sanitary officers has been arranged by the Sanitary Institute. They commence on the 17th of October at the Parkes Museum Margaret-street, at 8 p.m., on Mondays, Wednesdays, and Fridays. A series of inspections of water, sewage, and other works has also been arranged in connection with the lectures. The programme and particulars may be obtained of the secretary, Parkes Museum, Margaret-street, W.

The *Statist* offers a prize of a thousand guineas for the best plan of a Customs union between Great Britain and her Colonies. The competition is open to all, and the conditions will be published early in February. In the meantime, suggestions are invited from all interested as to what those conditions ought to be. The *Statist* adds that it will publish from time to time information bearing upon the question, and that especially it will pay attention to the restrictions imposed by existing commercial treaties both upon the United Kingdom and the Colonies.

A Local Government Board inquiry has been held at Gainsborough by Mr. F. H. Tulloch, M.I.C.E., on Tuesday last, in connection with the application of the Local Board for the transfer of their waterwork's loan from the original well scheme to a borehole scheme—see The Engineer, vol. lxviii., p. 4. Evidence was given by various members of the Board and by Mr. Percy Griffith, A.M.I.C.E.—representing Mr. Jabez Church, M.I.C.E., the engineer—explaining the reasons which led to the change of schemes and describing the one now proposed. No opposition was offered, and after a few questions raised by the inspector had been disposed of, the inquiry closed.

At the invitation of the Hammersmith Vestry, over a hundred delegates of the Wandsworth, Fulham, Putney, Barnes, Mortlake, Chiswick, and Brentford vestries, local boards, and other riparian authorities, together with representatives of the London, Middlesex, and Surrey County Councils, inspected the river Thames on Tuesday to ascertain its condition between Chelsea and Richmond after the recent construction of the new lock and weir at Richmond. The time chosen was when the tide was lowest. The effect of the construction of the Tower Bridge, with its enormous pier obstructions to the waterway, does not seem to have been considered. There is serious interference with the river traffic, the loss of waterway varying from 8in. to 12in. at Hammersmith to 15in. at Kew and Brentford. When the party approached Richmond a meeting was held at which was urged the desirability of convening a conference of all those bodies interested in the matter to consider the means of remedying the present condition of the river, which it is thought may best be done by erecting a new lock and weir at or near Battersea.

The designs for the three new torpedo boats authorised by the present Congress have been completed by the Chiefs of the Bureaus of Ordnance, Construction, and Steam Engineering of the United States Navy. According to *Engineering News*, these boats will be slightly larger than the Ericsson, now on its way to New York from the builders' yard at Dubuque, Iowa. The chief of the novel features to be introduced in the new boats is the placing of the propellers abaft the rudder. As compared with the Ericsson, the dimensions of the new boats will be:—

| | New. | Ericsson. |
|---|---|---|
| Length, load water-line | 160ft. | 150ft. |
| Beam, „ „ | 16ft. | 15·5ft. |
| Draught, „ „ | 5ft. | 4·75ft. |
| Displacement | 135 tons | 120 tons |
| Indicated horse-power | 2000 | 1800 |
| Speed in knots | 24·5 | 24 |
| Coal capacity, tons | 50 | 40 |

Three separate movable torpedo tubes above deck will be used, instead of three fixed 18in. Whitehead torpedo tubes below deck, as on the Ericsson. The quarters of the officers will be placed forward, and those of the men aft; and these quarters will be unusually roomy, owing to the removal of the tubes to the upper deck.

The Union Company's new twin-screw steamer Guelph, built for their service between Southampton and South Africa by Messrs. Harland and Wolff, of Belfast, went for a trip round the Isle of Wight on the 17th inst. No trial of speed at the measured mile was made, but the ship's performances throughout gave great satisfaction to all present. The Guelph is a sister vessel to the Gaul, the Goth, and the Greek, each of which have made several successful voyages to and from the Cape, but the newest steamer has had many improvements introduced in her internal arrangements and fittings. She is 400ft. in length, 47ft. in breadth, and 31ft. in depth, and 4916 gross tonnage. Her twin screws are driven by two sets of triple-expansion engines, developing an indicated horse-power of about 2200; the diameter of the respective sets of cylinders being 18½in., 30in., and 50in., and the length of stroke 42in. The vessel is fitted with a complete electric installation and cold chambers for the conveyance of fruit. Whilst providing a large cargo-carrying capacity on a light draught, the Guelph has complete accommodation for first, second, and third-class passengers, the majority of whom will be accommodated on the upper deck. The vessel, commanded by Captain J. Morton, leaves Southampton on Saturday next for Hamburg to take in cargo, and on her return to Southampton will start on her first ocean voyage on October 6th in the intermediate service. The company's new twin-screw steamer Norman, of 7500 tons, is nearly ready for sea, having been launched a couple of months ago at Messrs. Harland and Wolff's works at Belfast. She is appointed to leave Southampton on November 10th

## FOREIGN AGENTS FOR THE SALE OF THE ENGINEER

PARIS.—Boyveau and Chevillet, *Rue de la Banque.*
BERLIN.—Asher and Co., 5, *Unter den Linden.*
VIENNA.—Gerold and Co., *Booksellers.*
LEIPSIC.—A. Twietmeyer, *Bookseller.*
NEW YORK.—International News Company, 83 *and* 85, *Duane-street.*

## CONTENTS.

The Engineer, September 21st, 1894. Page

Antwerp International Exhibition .. 247
Harbours and Waterways .. 248
The Prospect Duplex Pump. (Illustrated) .. 249
Belgian State Railways — Brake Van for Goods Trains. (Illustrated.) .. 249
Glasgow Weirs. (Illustrated) .. 250
High-speed Engine. (Illustrated) .. 251
Road Bridge for Brazil. (Illustrated.) .. 252
A Bicycle Postage Stamp. (Illustrated) .. 252
Letters to the Editor—The Theory of the Steam Engine—The South Wales Colliers' Sliding Scale—The Graphic Statics of a Deck Chair—Work in Dynamos—Technical Education—Value of γ and J .. 254
New South Wales Railway .. 254
Railway Matters .. 255
Notes and Memoranda .. 255
Miscellanea .. 255
Leading Articles—The Scotch Coal Strike—The Vibration of Steamships .. 257
Panama Canal—Oil-fired Steamers for Harbour Use—American Tin-plate Manufacture .. 258
Literature .. 258
Books Received .. 259
Fatal Explosion at Tucuman, Argentine Republic. (Illus) .. 260
Primary Batteries for Launch Work. (Illustrated.) .. 261
Abstracts of Consular and Diplomatic Reports .. 262
Probable Iron Imports under the New Tariff .. 262
A Bridge 3100ft. Span .. 262
Rustless Coatings for Iron and Steel. (Illustrated) .. 263
American Engineering News .. 264
Letters from the Provinces—The Iron, Coal, and General Trades of Birmingham, Wolverhampton, and other Districts .. 264
Notes from Lancashire—The Sheffield District—The North of England .. 265
Notes from Scotland—Wales and Adjoining Counties—Notes from Germany .. 266
Launches and Trial Trips .. 267
The Patent Journal .. 267
Selected American Patents .. 268
Paragraphs.—Skelton and Brotton Sewage Disposal, 251—Naval Engineer Appointments, 252—International Tunnels, 259—Railways Abroad, 259—Railways in Japan, 267.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

J. N. B. (Newton Centre, Mass) —*You will see that your question has already been asked in a slightly different form by another correspondent.*

J. C. (Sheffield).—*You can obtain full information at any of her Majesty's dockyards, or by writing to the Admiralty, Whitehall, Engineers' Department.*

J. B. S. (Glasgow) —*The proper way to settle the question is to take indicator diagrams. You will then find whether the exhaust is throttled or not. We cannot pronounce any satisfactory opinion on this point. The exhaust pipe ought to be larger, but probably it is as large as the exhaust port. The heating pipes at A in your sketch make no difference unless water is allowed to accumulate. The steam pipe ought to be 2½in. in diameter all the way between the engine and the boiler. Very little would be gained by the alteration you propose. It would do some good, but not much.*

### SUGAR CANE CUTTERS AND SHREDDERS.

(*To the Editor of The Engineer.*)

Sir,—We should feel much obliged if you would allow us to ask for the address of manufacturers of modern sugar cane cutters and shredders.

Birmingham, September 17th. F. S.

### PARABOLAS OF LEAST RESISTANCE.

(*To the Editor of The Engineer.*)

Sir,—I shall be very much obliged to any reader who will give me the formula for calculating the parabola of least resistance for a given mass of lead ballast. Thus, suppose that I wish to use ten tons of lead ballast on a deep keel, the length of the spindle is not to exceed, say, 10ft. What must the diameter be at, say, every 6in. of length? Five Rater.

Southsea, September 14th.

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)* .. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
*Half-yearly* .. £0 18s. 0d.
*Yearly* .. £1 16s. 0d.
Thick Paper Copies—
*Half-yearly* .. £1 0s. 3d.
*Yearly* .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

## DEATHS.

On the 16th inst., at Santa Catharina, Brazil, suddenly, the result of a gun accident, Ernest Cunard Cummins, aged 27, electrician of the Western and Brazilian Telegraph Company's repairing steamer Norseman, eldest and beloved son of Mrs. William Alves Cummins, of 3, Upper Leeson-street, Dublin.

# THE ENGINEER.

*SEPTEMBER* 21, 1894.

### THE SCOTCH COAL STRIKE.

Thirteen weeks ago the Scotch coal miners, partially instigated thereto by the English Federation leaders, struck against a reduction of wages on which the Scotch coalowners insisted. The progress of the strike and its termination confirms the accuracy of the statement which we have often made, namely, that a strike which lasts more than a fortnight usually ends in the defeat of the strikers. Although the East Coast miners prolong the struggle, the West Coast men have nearly all returned to work. The Scotch leaders have been thoroughly discredited, and the miners have found out that they were really the cat's-paws of the Federation. To paraphrase a well-known saying, Scotland's trouble has been England's opportunity. The Scotch miners—who, by the way, are largely Irish and English men—have lost about £700,000 in wages. The iron trade has been for the time ruined. Multitudes of men have been discharged from the shipyards; the coal staiths have been rendered idle; the traffic on the railways seriously diminished; and all this to no purpose, save the profit and advantage of England. The lesson conveyed is very interesting and important; whether it will be of any service remains to be seen.

One of the first points worth notice is the deceptive character of the "Brotherhood of Labour," concerning which we hear so much in the present day from the platform and in certain newspapers and magazines. There is no special virtue in manual work which removes selfishness from the heart of the worker. Coal miners, bootmakers, dock labourers, moulders, are all mentally constituted like other men, and the mainspring of their actions is found in love of themselves. They are neither better nor worse in this respect than their fellow-men. But the schemes of the socialist and the union leader are based on the assumption that a lovely and delightful altruistic spirit is available, and that the working man considers nothing so much as the good of his neighbour. Sentimental clap-trap of this kind seems to take the fancy of the public. It pays the wagonette orator; but it will not bear the test of practical work. The men who most earnestly denounce sweating, for example, are those who render it possible. The Bloated Capitalist and Inexpressible Aristocrat do not buy slop clothes or cheap boots. These things are provided to meet the working man's demand for cheapness. While the collier is striking to make coal dear, and his leaders denounce the colliery owners for selling it below a given price, the Nottingham bootmaker, the Lancashire cotton-spinner, leave no stone unturned to get coal cheap. The collier grumbles because he has to pay so much for his shirts and his boots; the weaver and the bootmaker do what in them lies to make these things dear. If we listened to the union leaders, it would seem that there is no consumer save the rich man. The truth that the great mass of commodities of all kinds produced in this country is used up by the comparatively poor is entirely forgotten. The philosopher sees everywhere self, and self alone, as the mainspring of action; and self will, to the end of time, wreck the socialist and ruin the commune. There can be no such thing as prolonged united action of vast bodies of men until human nature has changed; and of such a change there is no evidence to be found. The Scotch strike supplies an admirable example of this truth. The Scotch miners were told that if they struck the English miners would back them up with considerable subsidies. They did send money for a couple of weeks, but nothing like the amounts expected, and latterly the contributions have almost ceased, and the English Federation leaders have coolly told the Scotchmen that they must make the best terms they can with the mine owners. The average fortnightly pay of each man on strike has been 2s. 5d. It is not remarkable that the Federation is execrated, and that the Scotch Union leaders are not safe from personal violence.

We have here an admirable example of the utter impossibility of getting large numbers of men whose interests conflict to pull together. All may go well for a time, but in the hour of difficulty they are certain to break apart. There is only one possible way out of this difficulty, and that, by the very nature of the circumstances, is prohibited. If three or four hundred thousand miners could be grouped into an army under the despotic control of a leader of genius and will power, great things might no doubt be accomplished. But such a leader could not hold his army together unless he had the power of life and death in his own hands; unless, in fact, his Provost Marshals could shoot or hang mutineers. It is difficult to believe that even under these conditions an army could be kept together when starvation began. But short of this autocratic power no one body of men will ever be got to work together for any period. In a little country like Great Britain it is impossible. How can it be possible all over the world? When the Durham miners struck, the Wales and Midland colliers redoubled their efforts; indeed, numbers of the Durham men went at the outset to Scotland, Wales, Staffordshire, anywhere that they could find employment, knowing very well and caring very little for the fact that they were playing into the hands of the consumer by enabling people to obtain elsewhere the fuel they could not obtain in Durham. It is always the same way. If a levy is raised to support a strike, the men paying the levy only work harder to get the money to pay it.

A Glasgow radical newspaper, the *Weekly Mail*, has been for weeks denouncing the coalowners, and urging the strikers to maintain a firm attitude. For weeks it has been unable or unwilling to realise the truth. At last the reality has dawned upon our contemporary, and a remarkable change has come over its methods. The following passage is so suggestive that we reproduce it:—"The fight has been a long and a hard one, and, looking back now, it seems to us that the Scotch miners would have made a better fight if they had been fighting for their own hand, and not tied neck-and-heels to the English Federation. They were led to expect that the Federation would support them with an allowance of a shilling per day; but, instead of that, many of the men have not got a shilling per week—certainly none of them more than sixteen-pence, and that not for the whole time. *The truth is that the interests of the English and the Scotch miners, like those of the English and the Scotch coalowners, are wide as the poles asunder.* The conditions of trade, of contracts, of everything, point to the impossibility of any effective alliance either in the interests of the masters or of the men. Therefore it is that as nothing more can be hoped for from the English Federation to enable the Scotch miners to continue the struggle, it would be monstrous folly if, by any delay on the part of the men in now returning to work, the settlement offered by means of the concession of the Board of Conciliation were endangered." How, we ask, does it come to pass that an influential Scotch journal should have taken thirteen weeks to find out the truth embedded in the words which we have italicised? Are we to attribute this ignorance of a truth obvious to every reasonable man who knows anything of the coal and iron trades, to accident or design? Union leaders will do well to take the words to heart, and bear in mind in future that the competitor whom any one working man has to fear is another working man. His foes are not the capitalists but those of his own household or his own trade.

But the Scotch strike has another lesson to teach; it shows that the conditions of supply and demand are too strong for combinations of producers. That which cannot be obtained at one shop can be bought at another, and the consumer is an exceedingly independent man in his ways. If the Scotch ironmaster wants to sell iron or steel, it must not cost more than iron or steel made in England or Belgium. The Scotch coalowners satisfied themselves that they could not sell coal at a price which would enable them to pay the existing rate of wages. They have proved this at an enormous cost to themselves. If the ironmasters had been prepared to pay more for coal, they would have intimated as much to the coalowners when they did not possess pits of their own. They did nothing of the kind. They shut up their works instead, and put out or damped down their furnaces. They have proved their sincerity in a way that we should think will satisfy even a Scotch miner. The lesson taught may perhaps bear fruit; at all events it seems to be extremely unlikely that Scotchmen will strike to please English Union leaders in the immediate future. The only satisfactory feature in the whole transaction is, that probably a Conciliation Board will be established; but that could have been done long since. To those who do not know human nature, it seems unreasonable that £700,000 should have to be wasted before men could see this. To those who do there is nothing remarkable in the matter.

### THE VIBRATION OF STEAMSHIPS.

Much has been written and said concerning the vibration of steamships, its causes and its remedies, but even now much remains to be said, and there are few subjects connected with naval architecture and engineering so little understood. We say this, of course, while giving Mr. Yarrow full credit for the work he has done in investigating the subject. But Mr. Yarrow directed his attention mainly to one type of vessel. The nature of the subject is such, however, that while it admits of specialisation, it demands generalisation. The principles involved are but imperfectly understood, and, indeed, in many respects overlooked. We propose here to bring before our readers aspects of the whole question which seem to be very frequently neglected.

In the first place, the word "vibration" is not properly defined. A particular passenger vessel is said to vibrate so badly that she is wretchedly uncomfortable. If we ask how she vibrates, we are told, "Why, in the usual way, of course!" Now, as a matter of fact, not only are there more kinds of vibration than one, but two or more of them may be found in different parts of the same ship at the same time; and until we know something definitely what the character of the vibration is, it is waste of time to attempt to prevent it. Speaking at large, vibration in a ship is of two kinds, lateral and vertical—that is to say, the stern, let us suppose, in the first case swings from side to side, in the second it jumps up and down. The latter is of the two usually the more unpleasant. We constantly find the two motions combined. Generally speaking, vertical vibration is due mainly to want of balance in the engine. But this is not invariably the case, nor does it cover the whole ground. Side vibration is in like manner generally due to the propeller; but, again, this statement does not cover the whole ground. Mr. Yarrow reduced to practical demonstration the fact known before in a more or less indefinite way, that vibration depended largely on the isochronism of certain motions of the engine with the vibrating period of the ship. It is enough to mention the fact here, because it has not any very close connection with what we are about to advance. No doubt the vibration of a ship may be reduced or augmented in many instances by altering the speed of the engines so as to put them out of step with the ship. But this has, as we have said, little or nothing to do with the matter in hand, which is a consideration of the forces which set up the vibrations, the magnitude of which may or may not depend on the "vibrating period" of the ship.

To begin, let us consider what would take place if it were possible to hold the propeller fast and permit the engines to work. In that case the ship would revolve on a longitudinal axis, with the propeller shaft for a centre; and although nothing of the kind takes place in practice, none the less is the effort there. In the well-known cigar-ship—which being a spindle and without a keel, depended on her ballast alone to prevent her rotation—there was provided a special ballast engine. A mass of lead weighing about 15 tons was hung pendulum-wise in the engine-room, and when the engines went ahead the pendulum was thrust over to starboard, and when they went astern it was thrust over to port by a piston in a horizontal steam cylinder, and so it balanced the effort of the engines to turn the ship round on her axis. The turning effort is due to the thrust of the connecting-rods against the guide bars, and it varies continuously in amount during each stroke, as the angle made by the connecting-rod with the guide-bars augments or diminishes. The thrust depends for its existence on the resistance to rotation offered by the propeller. It is clearly a transverse effort acting at right angles to the keel, and it can only be set up by a corresponding effort exerted in the opposite direction, or by two or more efforts not in the same direction, of which the effort in the guide-bars is the resultant. It by no means follows that the two opposing efforts must be in the same plane, and as a matter of fact, one is at the screw propeller and the other in the engine-room, fifty, a hundred, or more feet apart. If, now, the effort were constant, it would not cause vibration. But it is not constant; on the contrary, it is extremely variable, and beyond question it may play an important part in causing that lateral vibration of which we have spoken. Again, we have to take into account the action of the propeller. Although there is no proof whatever that a propeller sends aft or leaves behind it a twisted rope of water as Professor Fitzgerald believes, it is certain that the propeller in its revolution will throw water violently against the stern post and the rudder, and the succession of blows thus given, blade by blade, is very well calculated to set up lateral vibration in the stern of the ship, especially if she is weak. Some years ago a case of this kind came under our own observation. A passenger screw steamer of about 1100 tons displacement was exceedingly uncomfortable because of her excessive vibration. After two or three years' work signs of weakness were noticed about the stern frame and after body of the ship. She was docked, and a considerable quantity of iron was worked into her from the engine-room aft, by which she was stiffened materially. No change whatever was made in the propeller or engines. After the repair she was found to be a very comfortable ship, the vibration almost disappearing. The influence of the propeller is, however, so well understood that it is not necessary to insist upon it. But it is necessary to insist on the influence of the reactions which go on continuously in the engine-room, and which have nothing whatever to do with balancing the reciprocating parts. They are, as we have said, of the nature of a horizontal thrust, constantly rising and falling in amount, and this thrust is very well calculated to cause, as we have said, lateral vibration when combined with the effort of the propeller. In stiff ships it is not so prominent in its effect as in weak ships. In certain high-speed vessels with thin shells and weak frames, in which much, if not everything, has been sacrificed to save weight, the lateral vibration is often excessive, rendering the ship very uncomfortable. It is said that twin-screw ships are better off in this respect than those with single screws, because the effects of the engines revolving in opposite directions neutralise each other, and no doubt there is force in this contention. The engines in such ships never make precisely the same number of revolutions per minute except by chance. Lateral vibration does occur now and then, but on the whole the twin-screw gives immunity, provided, which is not always the case, that the propellers are accurately balanced. This balancing of propellers does not have nearly the attention which it deserves. It is forgotten that the tips of the blades often make sixty miles an hour or even more, and while a hundred pounds of metal more or less in the blade of a screw may seem a trifle, that weight moving at the rate of forty or fifty miles an hour can cause a great deal of trouble.

Almost all that can be said on the subject of balancing engines has been so well said by Mr. Yarrow in his paper read two years ago before the Institution of Naval Architects, that we think it unnecessary to go over the ground again. But we must insist on the fact that, while engines out of balance are pretty certain to cause trouble, it by no means follows that putting them in perfect balance will put an end to vibration. Some years ago a quick-running vertical engine caused a good deal of annoyance by vibration communicated to the building in the basement of which it stood. It was a single-cylinder inverted engine, with a crank disc cored out to partially balance the weight of the piston, cross-head, crank, &c. In the hope of getting rid of the vibration, a balance weight was put into the rim of the fly-wheel. The work was done with the utmost care. The packing was taken out of the stuffing-box, and the piston rings were removed so as to leave the piston quite free in the cylinder. Weights were placed on it equal to that of the rings. The balance was as perfect as it could be got. The engine was put together and started, but the results were most unsatisfactory. The safety of the holding-down bolts was threatened. The engine "wanted to walk about the shop," and the balance weight had to be very quickly taken out of the wheel. The thing was a failure simply because the fly-wheel was some 3ft. away from the crank, and the balancing was not effected in the same plane as the crank. In the same way it is quite easy to put balance weights on a marine engine which will do more harm than good. But this is not all. There is another agency at work which tends powerfully to set up vertical vibration. We refer to the steam efforts on the cylinder covers. On each of these there are stresses of 5 to 30 tons, according to the size of the engines, set up and tending alternately to lift the ship up and force her down. Many persons assume that these efforts are wholly balanced and opposed in the engine-room, but this is not so. The upward thrust on a top cylinder cover tending to lift the whole engine is not balanced by the downward thrust on the crank-pin save at the dead point. We have instead a couple composed of the crank-pin effort and the propeller's resistance to being turned round. The effort on the cylinder covers is simple and straightforward. The way in which it is taken up is complex, and there is no room to doubt that a very potent cause of vibration is thus introduced which is not sufficiently considered. We have then in every steam vessel, large or small, numerous efforts and stresses, which have nothing in common with those caused by want of balance in the matter of weight. We may construct a model, and cause the rotation of the crank-shaft by hand, and so demonstrate at will that by balancing we get rid of vibration, and by not balancing we retain that most objectionable feature. All this is quite true, but it is not the whole truth. When the crank is turned by hand we have only one set of forces to deal with—those due to the momentum and inertia of the reciprocating and rotating parts. But the case is quite different when steam is put into the cylinders. It is not different as regards the engines, but it is different as regards the ship. An excellent illustration of what we mean is furnished by outside-cylinder locomotives. No matter how carefully they are balanced they always have a tendency to run more unsteadily than inside-cylinder engines, and in the smaller and lighter engines "boxing" is always very apparent at certain speeds. The engines are thrown from side to side at the leading end by the alternating effort of the steam first on one cylinder cover and then on the other.

In conclusion, we may say that there is too much tendency manifested in the present day to believe that balancing engines will suffice in all and every case to make passenger steamers comfortable. This is not quite true. Balancing is good as far as it goes, and in some cases it goes very far, but it is not everything. In point of fact, there are dozens of efforts and stresses in an engine-room and a shaft tunnel which all tend more or less, because of their rythmical action, to produce vibration. Whether they will or will not do this depends on a great many circumstances which require the most careful consideration. Thus, for example, the position of the engine-room in the ship may have a marked effect. Thus, as a rule, to which there are no doubt many exceptions, the nearer the engines are to the mid-length of the ship the less is the vibration likely to be. It is, of course, impossible to go here very fully into a subject so abstruse. Our purpose will have been served if we have succeeded in directing attention to the truth that want of balance in engines is not necessarily the only reason why vibration takes place, and it is worth noticing that the actual rate at which vibration goes on is not always the same or nearly the same as that at which the pistons reciprocate.

We direct attention to the fact now, because certain high-speed steamers which have been constructed within the last few years are great offenders in the matter of vibration—it is perhaps as well to add that we are not alluding to Atlantic steamers—while others give no trouble whatever. Naval architects and marine engineers could do excellent service if they would investigate this question, and find out what is the reason for the difference. There is curiously little practical information on the subject available, probably because there has been so much theory written about it. Mr. Yarrow has done a great deal. It is now time that someone else pushed the inquiry further in a different direction and on different lines.

◆

### THE PANAMA CANAL.

THE issue of shares in the new Panama Canal Company has come as a surprise to the French public, who had never thought for a moment that the enterprise would again be put in hand. It was known that the liquidator had been making serious efforts to reconstruct a company, but the different financial bodies whom he approached did not seem inclined to lend their support to a scheme of such doubtful possibilities. At the same time it was necessary that something should be done without delay, in order to prevent the concession from irretrievably lapsing, as the Government of Colombia had only agreed temporarily to prolong the concession upon the condition that a new company should be immediately formed for carrying out the work. As this concession will expire in the course of a few weeks, the new concern has come into existence at the eleventh hour, and it will entitle those interested to claim a further extension of time for completing the canal. The floating of the new company has been an operation of great delicacy and ingenuity. It was, of course, impossible to rely upon the public subscribing any more capital to an enterprise of which the name is associated with nothing but disaster and misery; and it is not surprising that, so far as they are concerned, the new issue has fallen flat, so flat indeed that scarcely any notice is taken of it. Nevertheless, 300,000 shares of 100f. have been offered to the public, preferably to those holding shares in the old company as some compensation for their losses. In the event of the public refusing to take them up they will be purchased with the funds in the hands of the liquidator, M. J. P. Gautron. Another lot of 300,000 shares has already been taken up by three great financial bodies, and 50,000 shares have been offered to the Government of Colombia in exchange for the concession. The way in which the new concern has been sprung upon the public has given rise to a good deal of criticism, as it is felt that there is something behind it that the public are not permitted to know anything about. In the first place the smallness of the capital places the new company in a singular light. The issue is nominally for 24 millions sterling, half of which is said to have been taken up by financial concerns; but seeing how much these bodies have held aloof from the enterprise, it can only be assumed that their participation is conditional upon the public responding readily to the appeal. In the absence of this it is said that the other half will be provided for by the liquidator, who, upon this showing, must have a much larger sum in hand than the shareholders in the old concern thought. Had this confession been made a year or two ago there would have been an immediate demand to have the money distributed. Under the circumstances, the conclusion can only be arrived at that the liquidator is seeking to inspire confidence among the public by making them believe that there is plenty of money behind the concern, but it is very doubtful if this manœuvre will succeed. It is obvious that even if the company raises the whole of the capital asked for, it will not be in a position to carry on the work of cutting through the isthmus. Before operations are begun a great deal of expensive machinery will have to be replaced, and most of the capital will be swallowed up before the work is fairly under weigh. Another point that cannot escape observation is the reticence of the liquidator with regard to the constitution of the company and the project to be adopted. It is indeed rumoured, that M. Bonnardel will be president of the council of administration, and that the technical commission will be placed under the direction of M. de la Tournerie, but nothing definite about these appointments is known. It is, to say the least, considered very singular in Paris, that in promoting such an enterprise as the Panama Canal, it has not been thought advisable to take the public more into confidence, and these may be excused for thinking that there is nothing serious in this new issue. It at least serves the purpose of buoying up the old shareholders with hope, and of prolonging the concession of the Government of Colombia, which would thus keep the question open until such time as the financial condition of France may favour the project being taken up seriously.

### OIL-FIRED STEAMERS FOR HARBOUR USE.

SOME interesting facts as to the result of using oil as fuel on board harbour tugs at Chicago have been communicated to an American contemporary by Mr. F. U. Adams, chief smoke inspector of that city, preliminary to a full official report on the whole subject. The oil to be used is carried in tanks occupying the space usually allotted to coal bunkers; and from these the oil is pumped by a small pump in the engine-room and forced into a small pressure tank holding twenty gallons, from which it is led to the burners. The manner of feeding the oil to the furnaces—adopted after unsuccessful trials in other ways—consists in leading the burners in through the front end of the fire-box, so arranged that the oil is thrown in sprays towards the furnace door, striking against an arch which deflects it back towards the flues. In a test made between the oil-fuel tug and a similar tug burning soft coal over a distance of seventy miles, the result as to the relative consumption of oil-fuel and of coal, and the cost of each, was shortly this. The oil-fuel tug consumed 650 gallons of oil, worth 11·62 dols., and the competing tug burned 6½ tons of coals, worth not less than 21 dols. Both boats maintained a full capacity of steam during the entire trip; but while smoke and soot were copiously emitted from the coal-fired tug, there was entire absence of anything like smoke from the oil-fired one. The former, however, is the faster of the two boats, and she averaged a little over twelve miles per hour as against the eleven miles and a fraction averaged by the latter. Because of this, certain journals friendly to soft coal have attempted to construe the result into a victory for soft coal. The oil-fired tug can hold steam at 85 lb. for any length of time with a consumption of less than two gallons of oil per hour, or about 70 cents per day. To do the same work requires about 1½ tons of coal costing not less than five dols. In view of this, and especially considering the nuisance through smoke, ashes, and other drawbacks incidental to the use of coal, the advantages would seem to clearly lie with the oil-fired vessel, so far, at least, as suitability for plying in harbours and rivers is concerned.

### AMERICAN TIN-PLATE MANUFACTURE.

IT is a singular coincidence, yet it seems to be none the less real, that the passing of the Wilson Tariff Bill, instead of imposing a check to the development of the new industry in America connected with the manufacture of tin-plate, seems rather to have stimulated it. The reduction in the tin-plate duty of one-half is actually encouraging American outturn. The latest information of American doings in the tin-plate world points to the immediate erection of additional works in various centres, and to other preparations for greatly enlarged production. This is so alike in Pennsylvania and Ohio, from whence there is intelligence that contracts for the erection of new tin-plate mills have been given out by several iron firms. More convincing than all is an announcement this week that one of the largest American ironmasters now in this country is arranging with several friends for the formation in Pennsylvania of a tin-plate venture which will very greatly increase the American output, and will be backed by abundant capital. Another tin-plate plant which is to cost £50,000 is being erected in Pittsburg by capitalists who have hitherto had no experience in iron-making, but who are convinced that there is money in the future condition of the trade. This activity would seem to indicate that Trans-atlantic manufacturers believe that those earliest in the field will obtain the biggest share of the profits; and that they are prone to believe that American consumers will buy native-made tin-plate in preference to Welsh wherever it can be offered at the same price. This is an old policy on the part of the Yankees, who are very quick at seizing an opportunity. But to the Welsh tin-plate makers the position is not encouraging.

## LITERATURE.

*The Theory and Practice of Modern Framed Structures.* By J. B. JOHNSON, C. W. BRYAN, and F. E. TURNEAURE. J. Wiley and Sons, New York; and Kegan Paul, Trench, Trübner and Co., London. 1893.

[CONCLUDING NOTICE.]

IN discussing formulas for the strength of struts, our authors begin with one which they term a "strictly rational" one. Unfortunately, it is founded on bad mathematical manipulation, and is in fact wholly delusive. The formula is intended to enable us to deduce the average stress on the strut section from the elastic stress limit for the material when the load is such that the whole stress—made up of average or "direct" and of bending stress—equals this elastic limit. At page 144, if we put in Equation (1) the excentricity of the load $v = O$, and also write $\frac{1}{C}$ for the factor $\frac{1}{10}$ which the authors here use, it is easy to see that the formula reduces to the two equations $p =$ average stress $= C\,E\left(\frac{r}{l}\right)^2$, and $f - p = f - p$.

As the first of these does not contain $f$, the elastic stress-limit at all, it is evident that what the authors have got hold of is a high equation, so far as the relation between $p$ and $f$ is concerned. That is, their investigation gives $p$ the above value, whatever be the elastic limit, unless $p=f$. The authors take C=10, a rough mean between ratios found for various relative distributions of bending moment along a beam, a ratio which in different cases varies from 8 to 12. If C is put=$\pi^2$, which is nearly 10, the above is a reproduction of Euler's formula, the mathematical fallacy in which was demonstrated by Prof. R. Smith twenty years ago. The authors' method of converting this first formula (1) into Gordon's formula is altogether too bad to be fairly allowed a place in a book of a standard to which this volume justly aspires. They next develope Euler's formula, and then two others of their own which, taken as purely empirical ones, appear to have great merit. They ignore the theoretical investigations of Professors Smith, Claxton Fidler, and Perry on this subject, which, however, taken together, very clearly explain the whole actualities of the problem.

A decidedly good chapter follows on combinations of thrust and pull with bending stress, and on secondary stresses due to faulty formation of joints, &c. On page 156 is worked out a curiously useless problem, viz., to find the depth of beam which will give *maximum* stress produced by its own weight. This is *not* a misprint nor an error in calculation, and the heights calculated and tabulated in a long table are therefore those that ought to be sedulously avoided. The succeeding chapters on suspension, swing, cantilever and arch bridges are excellent, and contain a good deal that has probably not previously been published. Very simple and practically useful results are obtained for arches, from an assumption as regards the variation of section, which is a perfectly reasonable approximation, seeing that the section would properly be varied in this way if the arch were loaded only with a permanent load, and its shape were correctly chosen for this same load. The temperature stresses are very neatly deduced. A slight mistake has been made in the drawing of Fig. 257, page 217.

The next part, on deflections and stresses in redundant structures, follows a method which offers great practical facility for calculations and brings out many simple and interesting results. But it must not be forgotten that these all depend on the assumption that the actual stress intensities in all the tension members are the same, and again the same in all the compression members. Now, in bridges, the stress intensities cannot be practically kept the same in all members, some necessarily having very low stresses in them, especially in redundant structures. This applies more particularly to long and short struts whose average stresses are extremely different, and whose ratios of shortening again are still more different, seeing that they are not at all proportional to the stresses. A misprint of 2 for 8 occurs in the second of equations (5), page 222, and the language of the proof on page 221 is in a high degree inaccurate and obscure.

The reasons why equality of stress intensity cannot be maintained throughout a bridge are mainly three. First, there is the variation in strut stress referred to above; secondly, each member must be dimensioned with reference to the heaviest load that ever comes upon it, and these heaviest loads never exist simultaneously in all the members; thirdly, some essential members receive such small loads that considerations of corrosion, and other considerations dependent on the mode of manufacture of small sections, prevent these being given sections small in proportion to the loads coming upon them.

This chapter goes at length into the important question of the relative magnitudes of the parts of the deflection of a girder due respectively to chord strains and to web—*i.e.*, bracing-member—strains. They show that the part due to the strains in the braces may be sometimes more than half the whole deflection. The ratio increases with the ratio of depth of the web to span. This ratio is generally much larger in American than in European practice. Moreover, our authors exaggerate the relative magnitude of the web strains by overlooking the fact that the stresses in the braces—especially in the struts—have a lower average than those in the chords. They do not seem to have noticed that their strong insistance in this chapter on the relatively large importance of these web strains is inconsistent with what is said at the beginning of the book about "sections that are normal before bending remaining normal after bending." We say this not forgetting that in the web of a solid webbed girder the tensions and compressions are of lower intensity than those in the braces of a lattice girder.

In treating of the fatigue of metals, we notice unfortunate misprints of the brackets in formulas, (3), (4), (5), and (6) on pages 243, 244. The reasoning by which the authors lead to the conclusion that the Launhardt and Weyrauch formulæ are "rational in conception" appears extremely shaky, especially their analogy between fatigue in metals and fatigue in living muscle, an analogy wholly unscientific. Moreover their reasoning does not logically lead to the straight-line formulas of Launhardt and Weyrauch. Their logical conclusion would be an equation of the second degree, namely,

$$n^2 - m^2 = \text{constant},$$

where $n$ and $m$ are the upper and lower stress limits. This, however, cannot be a true formula because it would not apply to the extreme case in which $m = n$; and, therefore, the reasoning leading to it cannot be correct. A somewhat similar formula is recommended for other reasons by Professor R. H. Smith, namely, one of the second degree, which gives continuity to the law from the extreme in tension to the extreme in compression. The rules of Weyrauch and Launhardt do not give continuity even throughout the limit range to which they are intended to apply.

The treatment of the stresses in pins is interesting and important. American bridge engineers having a very extensive experience in this matter, their teaching ought to receive careful attention from those of other countries. As regards roller bearings, the authors repudiate as useless the various attempts at theoretic investigation that have been made. They give a formula—see 1, page 276—which thay state that they have deduced as a purely empiric one from experiments made at Cornell University. This rule is stated in a more complicated shape than it need be. A slight examination will prove that it is mathematically equivalent to the very simple law that the depth to which the roller and bearing plate are crushed down is in constant proportion to the load per inch length of bearing contact. This, if true, is most interesting. It would seem to indicate that the roller is deformed to a true elliptical cross-section for all loads, light and heavy. We know that this is not approximately true for rubber tires or solid cylinders; but it may be true for long steel rollers, in which the length is so great as to prevent any appreciable lateral—*i.e.*, axial, bulging.

Passing over the examples of detailed design of roof and bridge trusses, which, however, must be considered as one of the most useful parts of the book, we come to an interesting chapter on the "Æsthetic Design of Bridges." It is a novelty to find this side of a subject treated in a technical book, and one which deserves high commendation. Instead of scorning beauty, as so many engineers ostentatiously do, they ought to consider that they can only prove themselves educated men in so far as they pay a reasonable homage and obedience to the laws of good taste. As Mr. Molitor, the writer of this chapter, truly says:—"Since the civilised world lays a strong claim to good taste, and since bridges are monumental to the advances of civilisation, their design may well be subjected to the laws governing æsthetics." And again:—"Out of the consideration that the general public lays stress on the appearance of its bridges in cities, parks, &c., and often appropriates money to supply this want, we realise an advance in artistic taste." It is much to be deplored that it is the "general public" which in this matter forces the engineer occasionally to deviate into the paths of æsthetic rectitude, instead of the engineer being the leader and educator of the public, as he ought to be, into a correct appreciation of new forms of beauty appropriate to the developing improvement in the scientific design of structures.

But Mr. Molitor's almost invariable criterion of good taste throughout his whole discussion of bridges, is that they should without effort please the æsthetic sense of the mass of people who are very ignorant of the science of such things. He approves of modification of the latest developed scientific styles of designs, so as the more plainly to indicate the meaning of the whole by reference to more familiar and older forms. In other words, his main, if not his sole, criterion of æsthetic excellence is ability to please the popular taste, which of necessity must be ignorant of at least modern improvements. It seems to us that a higher and more absolute criterion ought to rule in this case. There are certain absolute, not relative, principles of gracefulness and fitness. If these are fully obeyed in the design and erection of improved styles of structure, then these will stand before the masses of beholders as great educative influences gradually leading them on to a higher standard of taste, and a truer appreciation of the real beauty of *fitness*.

With the great bulk of what is said in this chapter, however, we cordially agree, the discussions of details especially being most valuable. In what we suppose is one of the first attempts to deal seriously with such a subject, it would be strange if different people found themselves in entire agreement; and, in fact, there would be little hope for the progress of art if there did not exist a wide variety of opinion in matters of taste. For instance, we rather think that Mr. Molitor sets too high a value on perfect mathematical symmetry on either side of a centre as an *essential* of good artistic design. For example, if a bridge be exposed to strong winds, a certain want of symmetry in the direction of the prevailing strong wind is both rational and decidedly picturesque. It occurs to us that he does not sufficiently bring out the *artistic* value of masonry as the intermediary between iron or steel work and Mother Earth—it so suitably forms the connecting part between them, partaking as it does of the natural character of the one as regards its substance, and of the artificial or manufactured character of the other as regards its outlines and detail shapes. He states that stone naturally requires no preservative covering against the weather, and, therefore, requires no colouring; but it is only a few classes of stone that are not the better of a preservative covering, and the artistic fact that it is, as a rule, inadvisable to put any artificial colouring on stone, is, we suspect, more justly explained by its leading function as suggested in the last sentence. But in all practical suggestions on the subject of colouring we think Mr. Molitor a most trustworthy guide, and also as regards ornamentation. His insistence on the policy of bringing out into plain and easy relief the essentially different functions of the main members of the structure as a whole is excellent, and we very heartily agree with him in saying that the line of the roadway ought always to be made boldly apparent. The roadway is, after all, the chief end and aim of the whole structure; and yet, in not a few modern erections of large size, it is a puzzling problem, requiring the aid of the telescope and almost of the microscope, to find out where the roadway is, or if any roadway at all exists.

This book, as a whole, is a most valuable and important addition to our engineering literature. It represents a large degree of technical experience and skill, and it is the product of a vast amount of honest, patient, scientific labour. The duty of a critic leads him to point out what he conceives to be faults and errors; but if we have necessarily devoted much space to this part of our duty, we trust that we have also sufficiently indicated our sincere appreciation of the many high excellences of this work, and that we do not run the risk of being misunderstood to suggest that its faults are not of small importance in comparison with its merits. We offer a hearty welcome to this demonstration of American scientific industry, and heartily recommend it to our English professional men.

*The Physical Geology and Geography of Great Britain. A Manual of British Geology.* By the Late Sir ANDREW C. RAMSAY, LL.D., F.R.S., &c. Edited by HORACE B. WOODWARD, F.G.S., of the Geological Survey. London: Edward Stanford. 1894.

THIS is the sixth edition of a well-known book. It originated in the course of six lectures delivered to working men so long ago as 1863. The object of the course, as stated by Sir Andrew Ramsay, was to show how simple the geological structure of Great Britain is in its larger features, and how easily that structure may be explained to, and understood by, persons who are not practised geologists. The previous edition, which was published in 1878, contained an addition of nearly three hundred pages of detailed information. The sixteen years which have elapsed since then have seen great progress in all departments of geology, and the task of preparing the new edition which had become desirable was confided by Lady Ramsay to the competent and careful hands of Mr. Woodward. The editor has had the advantage of the author's copy of the fifth edition, with his manuscript notes and corrections, and Sir Archibald Geikie has revised the portion of the book dealing with the geology and scenery of Scotland. Anything like a critical review of a work so well known would seem to be unnecessary. Suffice it to say that Mr. Woodward has endeavoured to bring the information in the book up to date, in accordance with the general tenor of the author's plan and teaching, and that, so far as we have discovered, he has succeeded.

*Geology: An Elementary Handbook.* By A. J. JUKES-BROWNE, F.G.S, Member of the Geological Survey. London: Whittaker and Co., and George Bell and Sons; and Fourth-avenue, New York. 1893.

THIS is a little book intended to serve as a popular introduction to the science of geology. It deals chiefly with those branches of the subject which come under the head of physical geography—that is to say, the agencies concerned in the formation of rocks and the structural arrangement of the rock masses which make up the earth's crust. The author sets before himself the task of answering these amongst other questions: How was such a rock made? how does it come to be where we now find it? and why do some rocks contain fossils, while others do not? It is not too much to say that a study of the book will enable any diligent reader to satisfy himself, or at the least to take an intelligent interest concerning any rock he is likely to find in the course of his walks about the British Isles. The language is simple and clear, and the author, as is proper in a work of this kind, avoids as far as possible reference to controversial matter. Even those who have had little or no previous acquaintance with chemistry and mineralogy will have no difficulty in acquiring a great deal of information from it.

INTERNATIONAL TUNNELS.—There are two propositions for the construction of international tunnels which are already well advanced in the preliminary stage. One is a piercing of the Simplon, respecting which negotiations have been commenced some time back between the Italian and the Swiss Governments. The Federal Council have approved the official communication, containing a general plan and description of the proposed work, which has been forwarded for the consideration of the Italian Government. When they have expressed their views, it is arranged that the details of the joint enterprise will be settled by representatives of the two nations. A similar engineering work through the mountain barriers separating France and Spain has made some substantial progress, as the undertaking has practically commenced in the latter country. It consists of the establishment of two international lines of railway, each of which has its own separate tunnel. The first of these will start from Saint-Giron in France, having for its objective the town of Lerida in Spain, while the second will take its rise at Cloron in the Basses Pyrenees, and join on to the line from Saragossa to Barcelona. Each tunnel will be about five miles in length, and a period of ten years is assigned for the construction of the entire scheme.

RAILWAYS ABROAD.—A line from Bruges to Swevezeche has been conceded to the Société Nationale des Chemins de fer Vicinaux, by a recent royal decree which also authorises the State to subscribe some £10,000 towards the capital required. In addition to working the small line from Bangkok to Paknam, which, situated near the mouth of the river Menam, is the custom house port of the capital, the Siamese have granted a concession for a railway more in the interior of their country, with a preliminary length of sixty miles. It will need four or five years to complete this mileage, and it is possible that subsequently the line may be extended to the plain adjoining the banks of the Mekong, a river as well as a district in Indo-China, which may probably be known in future history. An extension of the railway Mondania to Brusah, as far as Chemlik in Turkey in Asia, has been petitioned for, from the Sublime Porte, as well as a branch to join the Anatolian line near Eski Shehr. From this latter place to Kutaiah, a distance of thirty-five miles, the works are well advanced, and it is expected they will be finished early in 1895. Most lines of railways, not excepting those in America, look small beside the colossal Trans-Siberian. A section of it from Oural to Omsk was inaugurated a few days ago by the passage over it of the first train, but the regular traffic will not commence to run for another month. It is usual to build temporary timber bridges along this line pending the construction and erection of the permanent iron structures.

## FATAL EXPLOSION AT TUCUMAN, ARGENTINE REPUBLIC.

We have received the following communication from an Argentine correspondent. He expresses his regret that the photographs are not of better quality, but that is not his fault, but that of the only available photographer:—

At 7.20 a.m. on the 24th July the town of Tucuman, which is about two miles in length by one in width, containing some 30,000 inhabitants, was suddenly startled by a terrific explosion, which, accompanied by the jarring of doors and windows, those in the more distant parts thought to be an earthquake. The news soon spread that a fatal locomotive boiler explosion had taken place at the workshops of the Ferro Carril Nacional Central Nook, on the west side of the town. This railway is a prolongation of the Ferro Carril Central Cordoba, runs to Salta and Injuy, and belongs to the National Government, by whom it is worked.

An investigation of the accident made within less than one and a-half hours of the event, and when the boiler plates were still hot, revealed an amount of destruction that is difficult to describe.

It appears that the eight-coupled compound—Worsdell and Van Borries—goods engine "Fiambala," No. 38, Sharp Stewart's 3536, built in 1889, was standing within a few metres of a 30ft. tank, preparing to take out a train, when it was discovered that the injectors would not work. The dome joint was also blowing, and the gauge glass also burst, consequently fitters were tinkering about these different parts when the boiler exploded. One or two men lived but a short time, six others were mangled beyond recognition. The fracture commenced at the side bottom corners of the fire-box, the crown and tube plate, greatly distorted, remaining almost *in situ*. The front of the fire-box was carried many yards, and only found the following day, after a diligent search, in a box wagon loaded with flour, it having fallen through the roof.

The shell of fire-box was hurled over eighty yards in front of the engine, and when opening out, had doubled back the engine frame, taking the right trailing coupled wheel off its axle as neatly as if done by hydraulic. The front tube plate did not travel far; the few remaining tubes and stays were all twisted like bits of wire. One plate of the boiler, with dome attached, after first striking and taking a large piece out of the iron tank, was thrown a distance of 250 yards into a quinta, and the inner steam pipe and regulator valve a considerable distance further, while another large piece of the boiler fell through the roof of the goods shed—120 yards away—hurting an employé, and partly burying itself in the ground. Another large plate fell about 100 yards away, narrowly missing a first-class carriage. Very few parts of the engine escaped damage, though the tender was hardly touched.

The adjacent rolling stock also suffered greatly. One 60ft. saloon carriage was thrown on its side and completely wrecked, though standing several yards away, as also were some half-a-dozen wagons more adjacent. The escape of several box wagons sheltering the families of the workmen was something miraculous. Needless to say, nearly all the glass in the station, a hundred yards away, was smashed, while *débris* covered the roofs of all the buildings, and a coat with an arm in it hung across a telegraph wire.

The engine, being only five years old, was practically as good as new, and the materials were excellent. Some few copper stays in the bottom front sides—nine or ten on each side—had previously given way, as also the stays joining the fire-box to barrel, and one, or perhaps two, of the longitudinal stays, but even with these defects the boiler would have easily carried the normal pressure of 175 lb.

The accompanying photographs taken the day after the accident give some idea of the effects of the explosion. Figs. 1 and 2 show the remains of the engine *in situ* with damaged carriages and wagons adjacent; running shed in the rear. Fig. 3 are the side and top plates of the fire-box shell, and the side plates of the fire-box thrown eighty yards away in front of the engine. These at the time of photographing had been turned over for examination. Fig. 4 is the front shell plate with mountings, and front plate of fire-box, found in the wagon of flour about eighty yards distant. Fig. 5 is the under side of crown plate of fire-box, and the high service tank close to. Fig. 6 is a fraction of the fire-box tube plate and *débris*.

Without going into particulars, or attributing blame to any particular individual or individuals, suffice it to say that the railway in question has forty-six locomotives on its books, and that only four are in working order, and that since the above accident occurred two others of a more or less serious nature have happened. This will give an idea of what a railway is like in this country under Government control.

Yo Se.

## PRIMARY BATTERIES FOR LAUNCH WORK.

We had recently an opportunity of examining a new type of primary battery which is being made by the Battery and Motor Co., of Victoria-street, Westminster. The works of the company are situated at Petersham Island, Richmond, and by special invitation we made trips in small electric launches provided with these batteries. After so many attempts have been unsuccessfully made to produce a primary battery which should be of commercial use for the production of light or power, we are rather sceptical about the advantages to be obtained from the use of carbon, zinc, and sulphuric acid. Still we were agreeably surprised to find that there was no "secret solution" deemed invaluable.

The chief point of novelty in this cell appears to be the employment of carbonised velvet as a coating for the carbon, and from this the material has been named "Velvo-carbon." Fig. 1 represents one of the so-called "palisades" which forms the carbon plate used in the particular cells we examined. The carbons themselves are simply ordinary arc lamp carbons, 9 mm. diameter, made hollow for coring, but with the core left out; each rod is 12in. long. Cotton velvet is cut into narrow strips about half an inch wide and is dipped into platinum chloride, and when dry is wound spirally upon the rod and fixed in position with ordinary paste. The rod with its covering is then put into a muffle and the velvet is carbonised, during which process the chlorine is evolved and the platinum in a spongy form is said to be deposited in the pores of the carbonised velvet. We are indebted to Mr. H. A. Barnett, the manager of the company, for details of the construction of the cells. Nine of these prepared carbons are then taken to form a palisade, and in each rod a piece of silver wire, No. 28 gauge, about 2in. long, is fixed into the core hole at one end by means of a small wedge of celluloid or ebonite wire. The group of rods is then fixed top and bottom into wooden cross pieces, and along the top cross piece a silver wire is fixed, which is connected to the several wires and acts as the common conductor for the palisade.

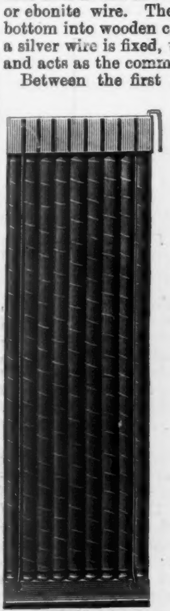

FIG. 1
VELVO-CARBON PALISADE

Between the first and second rods at each side of the palisade are placed ebonite strips slightly wider than the external diameter of the rods, and these prevent the zinc plates from touching the carbon. If the carbon rods are intended to rise above the surface of the electrolyte the upper ends are treated with ozokerit wax, but the palisades just described are intended to be kept submerged. The zinc plates used are each 12¼in. long by 3¾in. wide, they are amalgamated and No. 16 gauge thick of the brand V.M. 3 stars. These zincs have no permanently attached connections. The cell itself measures 10¾in. by 4⅜in. by 14¼in. high, is of ebonite, and weighs 2¼ lb. It contains twelve palisades, each weighing 14 oz., and thirteen zinc plates weighing 6¾ lb., besides about 12 lb. of liquid. The total weight of each cell in working order is 32 lb. The palisades and zinc plates are wedged up tightly in the cell by means of a pair of wooden wedges at one end of the cell. When a number of cells are used together in series, as in launch work, the end of the silver wire from each palisade of one cell is wedged between the corresponding palisade and zinc of the adjoining cell, and the connections of the last cell of the series are made to a brass omnibus bar faced with silver and provided with screws. Dilute sulphuric acid is used as the electrolyte, and a specific gravity of 1150 is preferred, although it may be used of a strength up to 1200. We have had no opportunity of making quantitative tests of these cells, but from reports made by Professor Jamieson, of Glasgow, it appears that the velvo-carbon gives much better results than ordinary carbon. With a constant potential difference of 0·5 volt the plain carbon gave a current of 0·26 ampère at starting, and after twenty-six minutes this had fallen to zero; whereas, when the carbon was replaced by a velvo-carbon and the same potential difference maintained, the initial current was 0·56 ampère, which gradually fell in twelve minutes to 0·488 ampère, and then rose, until at 114 minutes from the start it was 0·604 ampère.

With a cell weighing 17 lb. the output is stated by Prof. Jamieson to be one watt per pound, and it was capable of giving 20 ampères for a seven hours' continuous run on a consumption of zinc of 2¾ lb. per 1000 ampère hours, a mean of 5·1 lb. of zinc per electrical horse-power hour in the working circuit, and nearly 1½ lb. of commercial sulphuric acid is used per pound of zinc consumed. Mr. Barnett states that the zinc plates can be supplied at 5d. per pound, and the sulphuric acid at ½d. per pound, and if the battery be discharged at half its maximum output the cost of material consumed is 2s. 10d. per Board of Trade unit, while at maximum discharge the cost for materials would be 3s. 2½d. per Board of Trade unit. These prices, of course, seem high, and would entirely preclude the use of such a battery for constant work. It is possible, however, that for short runs separated by long intervals the cells might be of value. Our first trip was made in a small launch called the Velvo, 24ft. long with 5ft. 3in. beam and a punt-shaped middle; this was provided with fifteen cells, each being 12in. long by 4in. wide by 6in. deep, and about 6 volts could be obtained with the cells in series; each cell weighed 17 lb. The motor was series-wound, and built by Messrs. Mavor and Coulson, of Glasgow, and is shown in Fig. 2; it is intended for 10 volts, 50 ampères, and to run at 500 revolutions per minute. The maker's number was "349 Sayers' patent." The patent relates to the winding of the armature, to which we shall allude later on. The motor was stated to weigh 2 cwt., and to give an electrical efficiency of 90 per cent. The propeller was 13in. diameter. In this boat we had a run from Petersham Island to Teddington Lock and back. Since that time the battery has been somewhat improved in construction, and a larger launch called the Velvoca, built by Mr. Kerbey Bowen, of Maidenhead, has been acquired. This boat is 35ft. long, double skin, built without keel, and has a beam of 6ft. 6in., and will carry twelve persons; when fully loaded she is stated to draw 16in. of water. The cells were forty-eight in number, placed in the centre of the boat, and were of the large type already described, each weighing 32 lb., so that the total weight of cells was about 14 cwt. The motor was by Mr. Newton, of Taunton, weighing 6 cwt., and is said to give 80 per cent. electrical efficiency with 20 volts and 60 ampères, running at 500 revolutions per minute. Steering was effected from the bow, and the cells could be coupled all in series, or the two halves of the battery in parallel.

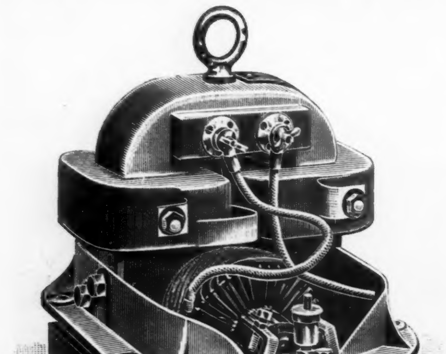

FIG 2

MAVOR AND COULSON'S MOTOR—SAYERS PATENT

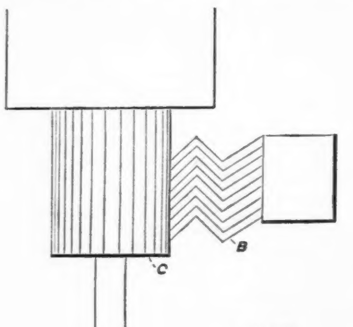

FIG. 3.

SAYER'S BRUSH

The acid was stated to be of 1080 specific gravity, and we started with eleven persons on board, and went from Petersham Island to Teddington Lock, then down to Richmond Lock and back to Petersham Island. Half-speed was used almost all the time, the two halves of the battery being in parallel. An ampèremeter was in circuit, and gave, when ascending the stream, a reading of 12; this required multiplying by two for the two halves, and also by a constant which was said to be 2·16, the result being $2 \times 12 \times 2{\cdot}16 = 51{\cdot}5$ ampères, and the potential difference was stated to be 13 volts. At full speed the reading was in a similar way, $35 \times 2{\cdot}13 = 75$ ampères, and the pressure said to be 22 volts. On the return from Richmond Lock the smell from the battery became very unpleasant, but this was stated to be only found when running at full speed. We were informed that with fresh zincs and acid the boat would run at half-speed for twelve hours with a load of twelve persons, and would cost 1s. 8d. per hour for material used in the battery. An ebonite pump is kept in the boat, and it is used to empty the acid out of the cells after the run is over. It is of course necessary to pump out each cell separately, as there is no fluid connection as there is in some batteries.

Both primary and secondary batteries have a very powerful competitor in the Daimler gasoline motor, which we see is now being used for launches on the Thames. Both suffer from the disadvantage of producing evil smells, and the Daimler motor sometimes causes great vibration, which is absent in the case of electric motors.

We referred above to Sayers' patents for armature winding. As many of our readers are doubtless aware, the connections between the armature winding and the armature sections are not made in the ordinary manner, but these connections, which the inventor calls commutator coils, are wound around the armature core in such a direction, and in such a position relatively to the position of the armature coils to which they are connected, that the electro-motive forces induced in them and the armature coil which forms a connection through the two commutator coils concerned at any time shall tend to neutralise one another if one of the commutator coils is under the pole piece and the other is not there at the moment when the brush connects the two sections of the commutator. The winding is so designed that the resultant electro-motive force shall be just sufficient to reverse the current in the armature coil and to reduce the current in the commutator coil to zero at the moment when it is leaving the brush. A sparkless break is thus obtained. The plates of the armature core are provided with deep, narrow radial slots in which the windings are placed. The brushes consist of flat copper ribbon, bent as shown in Fig. 3, and this form appears to give good results.

## ABSTRACTS OF CONSULAR AND DIPLOMATIC REPORTS.

*France: Drainage of Nice.*—Although the reduced mortality of Nice is mainly owing to improved drainage, the system is still incomplete; the construction of drains, according to the new system adopted by the Commission which sat in 1891, and divided the town into sections, one to be taken at a time, having to be suspended during the winter season, to avoid annoyance to the visitors. Much has been done, and the work is being steadily, if somewhat slowly, carried to completion. The system adopted is the "Tout à l'Egout," or everything to the drain. This system was much attacked during the past year, but in these parts an opinion is rarely expressed which is founded on the sole merits of the case, and has generally to be accepted *cum grano*—local politics being usually responsible for the greater portion.

*France: British goods in La Rochelle.*—The sale of British goods has decreased here owing to several causes. The increased protective duties, and the time and trouble required to clear goods through the Custom-house, would not alone have been sufficient to prevent their continued use, but French makers are reducing the cost of production in many competing articles, and selling them cheaper than formerly, helped by the lower rate of wages and the longer hours worked by their men. They are also taking much trouble to suit the requirements and taste of the public, where our manufacturers are stationary, paying no attention to, and perhaps not being aware of, the little details in which the people of this country have to be suited. As to many articles there is the old grievance about the absence of commercial travellers from England. Nearly all shopkeepers buy in this way, and if British goods cannot be thus obtained they prefer to take French ones. Nearly all English goods still sold here are purchased through Paris houses. The most important is coal, the import of which amounted last year to 200,842 tons, a decrease of 20,344 tons, or 9·2 per cent. under that of 1892; while the value rose from £1 7s. 1½d. to £1 8s. 5½d. per ton. Next comes pitch and tar, 5779 tons, valued at £11,000, all seaborne. Among manufactured and other goods imported through indirect routes, and of which the quantities cannot be ascertained, are:—Agricultural implements and machinery, particularly hay and straw cutters, mowing and reaping machines, ploughs, rakes, cycles, stone-breakers, and a number of articles of hardware of a trifling kind. All these articles meet with keen competition from French ones, and from this and the other causes before mentioned are sold in much smaller quantities than formerly.

*Italy: British Engineering Firms at Genoa.*—Considerable slackness and stagnation characterised the metallurgical industry of Genoa in 1892 and 1893, but the prospect was a little more hopeful at the beginning of 1894. Messrs. Odero and Co., of Sestri Ponente, who have an agreement with Messrs. Brotherhood, were fairly busy, turning out twelve torpedo boats, a light draught paddle steamer for the Servian Navigation Company, and a floating dock, also a number of air compressing engines for the Government. They have entered into an agreement with Messrs. Kirkaldy to construct their condensers and distillers, and have provided several sets both for the Government and merchant vessels. Considerable extensions are being made to their works, for the purpose of building two large passenger steamers and their engines for the Rubattino Line. At the boiler works of Messrs. G. Ansaldo and Co., of Sampierdarena, who work in conjunction with Messrs. Maudslay, many large locomotive and marine engines were turned out, some of the latter including one of 20,000-horse power for the armour-clad Sicilia, and one of 10,000-horse power for the fast cruiser Marco Polo. They were also constructing engines of 13,000-horse power for the cruiser Carlo Alberto, and of 13,500-horse power for the first-class battleship Ammiraglio di St. Bon. The boiler shop, one of the largest in the world, was, in the early part of this year, full of work, seventeen boilers having been turned out for the Rubattino fleet, which is being overhauled. Their locomotive department has been busier. There are being constructed nine locomotives for the Southern railways, and eleven of the large powerful ones knows as the Vittorio Emmanuele type, used on the main line between Rome and Turin. The firm builds ships and their material of the largest size, and recently built at their yard, Sestri, the Liguria, cruiser, of 20 knots speed, 2260 tons, and 7000-horse power; the Minerva, first-class torpedo catcher, of 22½ knots speed, 850 tons, and 4000-horse power; twenty seagoing torpedo boats, three cargo steamers, a passenger boat, tugs and other small craft, and machinery for them. They had on the stocks a first-class cruiser, the Guiseppe Garibaldi, of 20 knots speed, 6840 tons, and 13,000-horse power. At the works of Wilson and Maclaren many men were discharged last year, and the proprietors were working a good deal on stock, having a large assortment on hand of boilers, engines, engineering tools, &c., and had sold from stock two steam tugs of 200 and 120-horse power respectively, and were working on another of 250-horse power, the material for the boiler coming from Glasgow. They were also constructing a large hydraulic press for compressing gunpowder, the cylinder, of cast steel, coming from Sheffield. Steel ballast wagons, each carrying 20 tons, were being completed—rather to keep old hands employed than as customary or profitable work. At the end of March things were looking a little better, and a contract was made for another steam tug, though competition and scarcity of orders had reduced prices to their lowest figure. Repairs and additions to one of the "Veloce" line of steamers, and building steel barges for ammunition transport, were also undertaken, but the low price rendered it necessary to purchase the materials in this country—angles coming from Savona and Terni, and plates from Sestri Ponente—and a long time had to be waited for their delivery. A good deal of material for boilers came from the Steel Company of Scotland, Germany, and Belgium.

## PROBABLE IRON IMPORTS UNDER THE NEW TARIFF.

THERE is little probability, while present low prices continue, that the imports of iron and steel will be greatly stimulated by the new tariff. The imports for the fiscal year ending June 30th, 1894, were much below those for the same period ending June 30th, 1893, as will be seen from the following table:—

*Imports of Chief Iron and Steel Products for fiscal years ending June 30th, 1893 and 1894.*

| Articles. | 1894. | 1893. |
|---|---|---|
| Iron ore, tons | 218,550 | 683,056 |
| Pig iron, tons | 25,763 | 62,936 |
| Scrap iron and steel, tons | 2,822 | 18,836 |
| Bar iron, lb. | 22,763,623 | 38,947,476 |
| Rails, tons | 2,178 | 932 |
| Cotton ties, lb. | 1,792,392 | 3,744,482 |
| Hoop iron, lb. | 2,225,690 | 2,782 596 |
| Steel ingots, blooms, &c., lb. | 27,880,946 | 71,432,468 |
| Sheets and plates, lb. | 60 523,632 | 91,246,062 |
| Tin-plates, lb. | 454,130,026 | 628,425,902 |
| Wire rods, lb. | 56,228,155 | 97,067,082 |
| Wire, lb. | 8,710,399 | 9,305,075 |

The year 1894 cannot be regarded as a year of normal imports under the McKinley tariff by reason of the panic, the depression in business, and the tariff agitation. Even 1893 is hardly a fair year, as the uncertainty as to the future, with its depressing effects, began as early as the close of the campaign in 1892. It is very doubtful, however, if the reports for 1894-5 will equal those of 1892-3, while they may exceed those of 1893-4.

There may be a slight increase in the imports of iron ore in 1894-5 over 1893-4, but the figures will not reach those of 1892-3. Of the 683,056 tons imported in the latter year, 413,999, about two-thirds, came from Cuba, most of which went to the Pennsylvania Steel Company. With the works of this company practically out of the rail business, and with the low price of Bessemer pig, in the manufacture of which most of the imported ore is used, it seems impossible that there can be a material increase in imports. The price of Lake Superior ore is so low this year that considerable of it has gone east. As much or more will be consumed probably in the eastern furnaces next year. It is also true that the demand for Spanish ores in Europe is increasing, and must increase each year, while the supply is by no means greater.

The pig iron imported is of a high grade and special iron, largely ferro-manganese, ferro-silician, and charcoal for steel. The average declared value of that imported in 1892-3 was 25 dols. a ton, in 1893-4 a little less, but still some 23 dols. a ton. As this iron was imported to meet actual deficiencies in production in this country, it is not probable that its importation will be at all stimulated by the reduction in the duty.

Scrap iron is not a product, though it interferes to some extent with both pig iron and bar iron. Its importation is always uncertain, but with the low price of pig and the low rates of puddling that prevail all over the United States, especially along the coast, it can hardly be profitable to import scrap regularly. It is evident from the declared values that the scrap is special. The value of the 2822 tons imported in 1893-4 was 45,967 dols., more than 19 dols. a ton.

The bar iron imported, which in 1892-3 was 17,888 tons, and in 1893-4 10,162 tons, was also special iron of a high grade, largely charcoal bars for steel making. Of the 38,947,467 lb. imported in 1892-3, over 32,000,000 lb. were from Norway and Sweden. The value of that imported in 1892-3 was some 41·50 dols. a ton, and in 1893-4 some 42 dols. a ton. This is not common bar iron or even so-called marked bars. There will be little increase in the imports of this bar except as it is needed to re-work into high priced steel, and will not affect the market for merchant bar.

Our manufacturers can hold their own in steel rails. Most of the imports will be at points far away from our mills, chiefly on the Pacific coast.

The imports of steel ingots, blooms, &c., will probably increase somewhat in 1894-5 over 1893-4, though we doubt it if they reach the amount of 1892-3. We have made wonderful strides in our methods and machinery for the production of blooms and billets since June 30th, 1893. Much of that imported in that fiscal year was basic. We are in a better condition now to meet competition from abroad than we were then, and with some reduction in wages can hold our own and keep our trade. There is hardly a product that has declined in price in the United States in the last two years so much as steel blooms. The average price in the early part of 1893 was 22 dols. a ton; a better article has been sold in the last few months at 16 dols. to 16·50 dols., though at no profit, if not at a loss; 17·50 dols., which is a low price to-day, is a better figure.

We cannot speak with as much satisfaction as to the imports of the thin irons and steel. The amount of cotton ties undoubtedly will increase. Indeed, this industry is practically lost to us for awhile. Some more hoops and bands will be brought in unless we can find means to produce more cheaply than now. We shall continue to import sheets and tin-plate, and in large quantities, though all of our market will not be captured by foreign workers, as they fondly hope, if there is a judicious co-operation between employers and employés. It looks as though we were going to make strenuous efforts to increase our production of black plate for tinning, and that an increasing amount of tin-plate made in this country will be from American black plates.

To sum up. In our judgment, while present low prices rule there does not seem much probability of an increase in imports except of the thin irons, as cotton ties, hoops, sheets, and tin-plates. Should there be an advance to fairly remunerative prices, however, the situation would be different, and an increase of imports might be expected.—*American Manufacturer.*

## A BRIDGE OF 3100 FEET SPAN.

FOR some time past there has been a project to build a bridge over the Hudson River at New York City, but the extent and nature of navigation have made it necessary to avoid piers in the waterway. One company has already completed plans for a suspension bridge of 2900ft. span, and an Act of Congress granting another charter to a company which proposed a cantilever bridge, directed the appointment of a commission of prominent bridge engineers and an army engineer to consider and report upon what length of span, not less than 2000ft., would be safe and practicable. They report in favour of a suspension bridge of 3100ft. span as preferable to a cantilever span of 2000ft., a great difference in cost resulting from the deep and difficult foundations required for the latter. The following is an abstract of the report:—

"In making comparative estimates your board selected a location midway between Fifty-ninth and Sixtieth streets, but the difference between this location and one further north, within the limits of the Act, has been considered so far as it affects the general conclusions. The minimum length of span which may be considered is 2000ft., which your board have interpreted as meaning 2000ft. in the clear. The maximum length of span would be a clear span between the pier headlines, this distance varying from

3130ft. at Fifty-ninth Street to 3080ft. at Sixty-ninth Street. The objections which have been raised to a pier in the river apply with equal force to any pier located between the end of a 2000ft. span and the pier headline, the pier being objected to as interfering with the use of the river for harbour purposes, rather than for through navigation. The plan submitted to your board has located the 2000ft. span, in accordance with the requirements of the New York charter, next to the New York pier headline, thus placing the west pier about 1000ft. from the New Jersey pier headline. If the span is increased beyond 2000ft. any injury done to the harbour by obstructing the approach to piers on the New Jersey shore would be greater than any benefit gained by increased width of channel span. Your board have considered that navigation would not be benefited by making a span of greater length than 2000ft., unless such span could reach from pier headline to pier headline, and have, therefore, confined their examination to a span of 2000ft. in the clear as compared with such single span. It must be noted, however, that the pier headlines are artificial, and are subject to change under existing laws. The width between pier headlines at this location is about 400ft. greater than a point two miles below. A small encroachment beyond these pier headlines could be permitted without essential harm; it would obstruct navigation no more than a vessel lying across the head of a pier. A span of 3100ft. in the clear would meet all requirements of a single span.

"The plans submitted by the bridge companies provide for a cantilever bridge carrying six railroad tracks. This number of tracks is the least that has been proposed by any company which has contemplated bridging the Hudson River opposite the city of New York. Your board have, therefore, thought it right to make estimates for a bridge furnishing this accommodation. The fact that the river must be kept unobstructed during erection limits the plans to cantilever and suspension bridges. The plan submitted by the bridge companies provides for a steel cantilever bridge. In the first place, your Board are of the unanimous opinion that a cantilever span of 3100ft. in the clear could be built, and would be a safe structure. In the second place, your board have considered that the practicability of such a structure would depend upon its cost, and to determine this practicability have made comparative estimates of the cost of two cantilever bridges, with clear spans of 2000ft. and 3100ft. respectively. These estimates are comparative rather than absolute; the benefit of the doubt, where any exists, has been given to the longer span. The estimates include both substructure and superstructure, but have been made in round numbers and do not include the costs of tracks and other features, which would be common to both plans."

The board also goes into the question of rock foundation for the bridge, and says that at each pier head line the depth to rock is about 125ft. At the point in the river where the pier would be built in case a 2000ft. span was decided upon, the depth as to the rock is 260ft. All estimates have been made for rock foundations. The board has assumed that the masonry finish for piers would be 50ft. above high water. "The east pier of the cantilever bridge, with a clear span of 2000ft., would be immediately back of the New York pier head line, where the rock is 125ft. below mean high water. The west pier would come in the river where the rock is 260ft. below mean high water. The east anchorage would be within the shore line, where the rock is not more than 20ft. below mean high water, and the west anchorage would be immediately west of the New Jersey pier head line, where the rock is 125ft. below mean high water. The site of the west anchorage calls for an anchorage span 100ft. longer than is shown on the plans submitted by the bridge companies."

The cost of the east pier is estimated at 3,464,000 dols.; west pier, 9,710,000 dols.; east anchorage, 431,000 dols.; west anchorage, 1,038,000 dols. The east pier would consist of four cylinders of 866,000 cubic feet each, and the west pier of four cylinders of 1,880,000 cubic feet each.

Concluding upon the 2000ft. cantilever plan, the board says:—"A careful estimate prepared by the bridge companies makes the weight of the superstructure 230,000,000 lb., including the main span, the towers and the two anchorage spans, covering a total length of 4120ft. The cost of this bridge would then be 25,443,000 dols. This is the cost of a cantilever bridge of the minimum span which your board are authorised to consider, the length of the entire structure from anchorage to anchorage being 4320ft. As this plan of bridge is the one which the New York and New Jersey Bridge companies have selected as the bridge they wish to build, its cost must be accepted for present purposes as the cost of a practicable structure."

Of the 3100ft. cantilever plan the board gives the details of the main features of its construction, and estimates the cost at 51,128,000 dols., and adds:—"Your board are of the opinion that the additional cost of the long span cantilever bridge is so great that it must be considered impracticable."

"A suspension bridge is another possible form of construction at this location. Like the cantilever, it can be erected without false work; unlike the cantilever, it has not generally been considered well adapted to railroad uses. It has less rigidity than the cantilever and deflects more from the combined effects of temperature and load; the flexibility of the cables tends to cause vertical undulations of the platform under a moving load, which are more objectionable for a railway bridge than for a highway bridge, where the live load is less concentrated and is applied less rapidly. These objections lessen in importance as the span of the bridge and the proportion of the dead to the live load increases.

"In a bridge with six independent tracks the condition of the railroad service approaches that of highway service, and the position of trains which will produce a maximum disturbance would be of very rare occurrence. The inclination of the platform longitudinally and transversely, arising from the undulations of the cables under the effect of moving trains, can be reduced within unobjectionable limits by a proper system of stiffening. The effect of wind on cables and platform can be taken care of by cradling the cables and by a lateral system of bracing in the platform similar to that used in truss bridges.

"A single railroad track suspension bridge of 850ft. span has been in continuous use under restrictions of load and speed for nearly forty years at Niagara. With this example before us a six-track railroad suspension bridge of 3100ft. clear span cannot be dismissed without careful consideration. Your board have therefore investigated such suspension bridge with great care, and it is their opinion that it could be built and that it would be a safe structure.

"As this opinion may be thought a departure from general opinion as to the adaptability of the suspension bridge to railroad service, it is proper that the board should state their reasons therefor, and explain the features of the plan adopted by them for a comparative estimate in more detail than was done for the cantilever plans."

Discussing the plan for a lighter structure than has been described, costing 30,743,000 dols., the board says:—

"The calculations of the cost of the suspension bridge which has been described have been made as nearly as possible on the same basis as the estimates for the cantilever bridge, without taking into consideration the fact that the cantilever bridge would be strained nearly to its full capacity by a load 1000ft. long, while the suspension bridge would be fully strained only when covered by a load three times that length. Furthermore, no allowance has been made for the fact that the maximum strains in the stiffening truss would occur only under combinations which might not arise once in a century, and which could be prevented by simple police regulations. The only subject referred to your board is to recommend what length of span not less than 2000ft. would be safe and practicable for a railroad bridge to be constructed over the Hudson River between Fifty-ninth and Sixty-ninth streets. A single span from pier-head to pier-head, built on either the cantilever or suspension principle, would be safe. The estimated cost of a 3100ft. clear span cantilever being about twice that of a shorter span, your board consider themselves justified in pronouncing it impracticable on financial grounds. As the cost of the single span suspension bridge is almost one-third greater than that of the 2000ft. cantilever, your board are unable to say that such greater cost is enough to render the suspension bridge impracticable."

## RUSTLESS COATINGS FOR IRON AND STEEL.[*]

By M. P. Wood, New York City, Member of the Society.

(*Continued from page 232.*)

*Process for enamelling cast iron.*—The records of the Patent-office show many formula for compositions and designs of furnaces used in the process for enamelling cast iron. But few, if any, of either the compounds or furnaces materialise on application, generally leaving the party to his own devices for accomplishing the desired results. There are only two processes by which a satisfactory enamelled surface can be given cast iron. In the first, or hot process, the iron, heated to a bright red, is powdered by a sieve with a flux powder—the borosilicate of lead—then heated until the flux fuses, and is then powdered with a more fusible flux, forming the glaze of the enamel. This is the only direct enamelling process, and is dangerous to the operator, expensive in application, difficult to apply to large articles, nor does it allow of decorations. The second process consists of coating the cast iron with a kind of pottery, by three distinct and successive operations in the furnace. In the Bertrand process the article is first coated with the magnetic oxide as described above, then brushed over or dipped cold into the borosilicate of lead, coloured with metallic oxides, to which is added a little pipe clay to give the bath more body. The article thus covered is put into the furnace, the enamel adheres and vitrifies at the ordinary temperatures used by enamellers. By putting a coating of coloured enamel with a brush on the first plain coat of enamel, it is possible to make any desired decoration, which may be burned in at one operation. The process is particularly adaptable for outdoor vases, statuary, columns, railings, balusters, &c. The results due to the first oxidation with magnetic oxide are remarkable as much for their colour as for the tenacity of the enamel and its resistance to rough usage. The process is adapted to articles of any size or shape, is not dangerous to apply, and is comparatively cheap in application. The back numbers of the *Scientific American* contain some valuable suggestions and information upon the above and other processes for the protection of iron, for which the writer cheerfully renders acknowledgment.

A process of forming a black or magnetic oxide that has a limited application, but worthy of mention as containing some possibilities for the future experimenter, is the Maritens patent process, in which the article to be oxidised is connected to the anode pole of a galvanic battery and immersed in hot water, when it becomes oxidised. A repetition of the process is necessary to secure a favourable result. Full information and detail of the process is given in a publication by Dr. George Langbein, of Leipzig, Germany, of which there is a translation with additions by William T. Bramet, editor of the *Techno-Chemical Receipt Book*, 81, Liberty-street, New York. In this process the water is decomposed by electrosis, the hydrogen being set free, while the oxygen goes to the iron to form an oxide coating. This process appears to be the progenitor of the electric welding process that attracted so much attention at the Columbian Exposition. In the latter case the strong current from the dynamo causes so rapid a decomposition of the water as to surround the immersed article with an envelope of hydrogen of so high tension that it prevents the escape of the heat generated by the decomposition of the water, and a rapid rise in temperature to the welding point results; the oxygen being set free, no oxide forms. The weaker current used in the Maritens process simply reversed the welding method.

*The Gesner rust-proof process.*—This process for the preservation of iron and steel is of comparatively recent introduction, and, like the Bower-Barff process, forms a coating from the metal itself that it is depended upon to protect.[‡] While the Bower-Barff process forms a magnetic oxide coating, the Gesner process claims to change the surface of the metal into a compound of hydrogen, iron and carbon, which is designated as a double carbide of hydrogen and iron; analysis of treated articles showing the presence of hydrogen in quantities from two-tenths of one per cent. and upwards. This coating does not scale off by mechanical injury; articles treated can be bent cold to an angle of 45 deg. without injury, does not alter the dimensions of the articles treated, screw threads and nuts running together as freely after treatment as before; while the Bower-Barff process when carried to the point of forming a heavy coating of magnetic oxide, materially increases the size of the parts, and has to be allowed for in fitting up of finished and jointed parts, such as hinges and loose joints. A claim made for articles treated by the Gesner process that they are unaffected in strength appears to have some foundation. The record of a number of tests made at Philadelphia on an Olsen testing machine show that the wrought iron samples were comparatively unaffected in strength by the treatment, while the steel articles showed a loss in strength of about 5 per cent., and a gain of 5 per cent. in elongation, evidently from the annealing action of the muffle. Cast iron pipe treated shows that the pores of the iron are filled and the strength materially increased. Cases reported show an increase in bursting pressures of over 100 per cent.

The colour of the treated articles is a fine deep blue-black. Tempered articles, such as springs, bayonets, edge tools, &c., cannot be treated, but in some cases articles can be hardened and tempered after treatment. The process does not necessitate the use of skilled labour; after being established ordinary working men are all that is requisite. The process is adaptable wherever tinning or galvanising are employed to withstand atmospheric effects, and is materially cheaper than those methods. Among the adaptations for this process can be named: office railings, grilles, gates, wrought, cast, and malleable iron pipes and fittings, steel and iron shingles, corrugated sheets for roofing, polished wrought iron pipe for bedsteads, steam radiators, builders' and art hardware, architectural ironwork of all kinds, gun fittings, &c. These articles can be treated in small lots for prices from four and a-half to seven cents per pound, and large pieces wrought iron pipe in 20ft. lengths in quantities will not cost over one cent per pound, including manufacturer's profit. One of the principal articles thus far treated is a clock tower on a storage warehouse on Schermerhorn-street, Brooklyn, the clock dials of which are of wrought iron scroll work, 16ft. in diameter. The surface of the treated articles appears to facilitate the spreading and adhesion of paint if any is subsequently required on the structure.

The articles must be cleaned from scale to secure a good result, though the removal of oil and grease due to machining processes is not necessary. The apparatus and process of treatment is, viz.:—Two ordinary clay gas retorts—Figs. 1, 2, and 3—of any required length from 7ft. to 20ft. or more are set side by side with a furnace and grate below and between them, same as a gas retort setting. Suitable doors are fitted to one or both ends of the retorts as used for gas retort work. These retorts are heated to 1000 deg. or 1200 deg. Fah., as may be determined by the character of the articles to be treated. The articles are placed in the retorts and exposed to the heat for twenty minutes, or until they attain approximately the heat of the retort or muffle, when steam at low pressure is admitted to the inside of the retort through an iron pipe lying on the bottom of the retort and called a hydrogen generator, which decomposes the steam, hydrogen being set free, which fills the retorts, the surplus pressure passing out by a purge pipe sealed in about 1½in. of water to prevent ingress of air to the retorts. This steam treatment is kept up for thirty-five minutes, when a small quantity of naphtha—a pint or more—is injected by gravity into each retort and allowed to flow for ten minutes. The hydro-carbon is then cut off, and the steam which has been allowed to flow during the whole operation is continued some fifteen minutes longer. The whole time employed is therefore an hour and twenty minutes for articles of ordinary size and weight, such as builders' hardware, &c. The articles remain in the muffle sealed from air until the heat has fallen to about 800 deg. Fah., when they can be removed without danger of scaling. Ornamental objects, art hardware, &c., while hot are given a bath in whale or paraffin oil, to render them even in tone, prevent finger marks, &c. The process appears to be almost indentical with the Bower-Barff, with the exception of the use of the naphtha, which gives a foundation to the claim for the formation of a carbide that hastens the process; the time of treatment being materially lessened in the Gesner process than by the Bower-Barff to get the same thickness of coating. A number of plants for the working of this process are in operation in various parts of the United States, the principal one, the South Brooklyn Rust-proof Iron and Steel Works, 176, Sullivan-street, near Atlantic Basin, South Brooklyn, has a capacity of two tons daily output of small articles like builders' hardware, and six tons of pipe up to 7½ft. in length, and can treat articles up to 20ft. in length. Members of the American Society of Mechanical Engineers are welcome at any time to inspect the works and product, Mr. Geo. W. Gesner, proprietor, being in charge of the plant. A number of samples of rough surface and polished work are submitted for inspection.

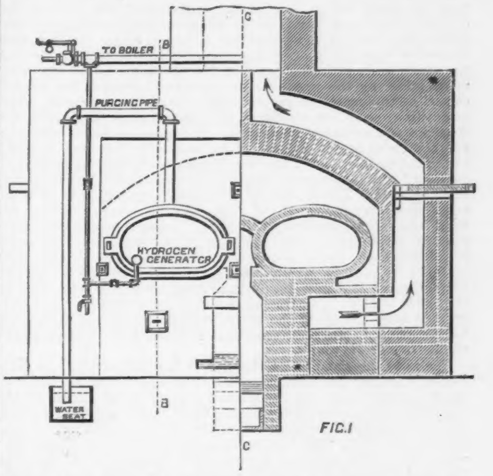

FIG. 1

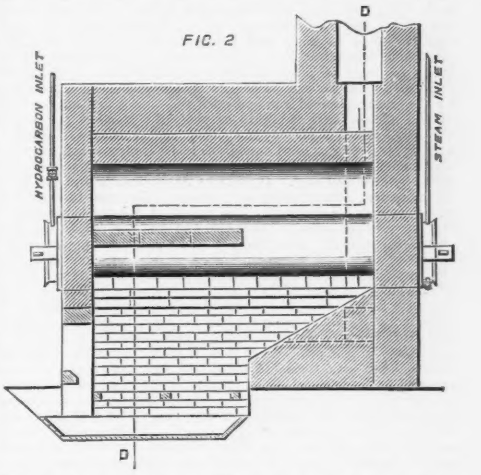

FIG. 2

After quoting at length an article from one of the technical papers, the author went on to say:—I think the presence of the scale found in most boilers acts as a partial preservative, as in general the shells of all types of boilers show the effects of corrosion more upon their external than internal surfaces. Boilers using perfectly pure or distilled water are more liable to pitting than a general corrosion over the whole surface of the shell and tubes. Why this is so is a mooted question. Pure hot water is a strong solvent of nearly all bodies; steel and iron do not escape its action, as the collapse of the Boston, Mass., hot water circulating system forcibly shows, and is fresh in the minds of all engineers. The Heine boilers that furnished the hot water, under a pressure of 450 lb., for the system in question, were comparatively unaffected, and other boilers and pipes under similar conditions have worked for years without showing the tendency to melt away as did the street pipes in this case.

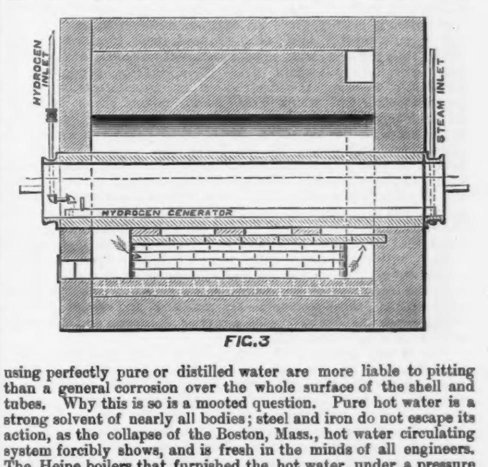

FIG. 3

The course of the Admiralty in causing all boiler plates to be pickled and cleaned from the scale of manufacture is in the right direction, and should be extended to all the plates used in the construction of ships. In fact, all iron and steel requiring protection from corrosion other than by the magnetic oxide processes, and that depend upon paint for their protection, it is an indispensable condition that the scale must be removed in order to secure the best result. When this is done and strictly pure red lead is mixed with pure raw linseed oil that has escaped the manipulations of the whale or Menhaden oil merchant, a paint is produced that will unite so closely to the iron or steel surface as to be only secondary in preservative qualities to magnetic oxide in resisting atmospheric effects. The writer cites from his experience a number of wrought iron tie bars that in an outdoor exposure of over fifty years were as unaffected from rust as though they had been up only a week. Examination showed that the bars had been scaled before painting, and had received two coats of pure red lead and oil paint at the date of their erection, and from their location in the structure could not have been repainted without removal from their position.

---

[*] Presented at the Montreal meeting, June, 1894, of the American Society of Mechanical Engineers.

[‡] United States patents to George W. Gesner, No. 376,874, January 24th, 1888. Apparatus for oxidising the surfaces of metals; described in the *Official Gazette*, vol. 42, page 343. No. 379,866, March 20th, 1888. Treatment of metals; described in the *Official Gazette*, vol. 42, page 1268. See *Iron Age*, April 3rd, 1890, for an illustrated article of the process and apparatus; also the *Engineering Journal* (Forney's), April, 1891, for description of the process.

How rapidly rust will form beneath the scale of manufactured iron, one need but to look at the trusses and iron work of the elevated railways of New York to recognise the importance of this preliminary step in the protection of the surface. In this case successive coats of a poor, cheap paint, are spread at intervals over the whole easily accessible parts of the structure; no efforts being made either by the engineers or painters to remove the blisters caused by the corrosion in progress beneath the first coat. How long this process can continue without seriously weakening the structure is a matter of guesswork. A suggestive lesson upon this point is found in the collapse of an iron and slate roof, covering the retort room of one of the New York Gas Works, that suddenly gave way without warning, and played the part of an extinguisher to all beneath. The tie rods of the trusses proportioned to withstand five times the weight of roof, with the usual allowances for wind and snow pressures, had wasted away beneath successive coats of paint and coal tar applied, until rupture came as a matter of course even under conditions of a minimum strain. The material in the old Hammersmith Bridge across the Thames at London was bought by Sir William Arrol to use for false work at the Forth Bridge. The iron after sixty-two years of service was as good as new. Many of the parts were inaccessible, and had not been repainted since their erection. Pure white lead paint was at the bottom of the secret.

The red houses and barns that are so familiar a feature in New England scenery have been standing from fifty to over one hundred years exposed to an atmosphere and climate charged with all the conditions that cause rapid decay. These buildings, when erected, received in general two coats of red oxide of lead and pure boiled linseed oil paint, that has so thoroughly protected them, that where the paint has in many cases been completely cut away by the sand blast of the Cape Cod storms, the wood sheeting is in good condition and the nail heads are as perfect as when first driven. But the paint was honest, no red or brown oxide of iron with a liberal addition of barytes, whiting, pipe clay, ochre, and other "almost as good as lead" compounds, mixed with sour sig and oil so fishy that one could almost detect the fish scales on the painter's brush, entered into this work. The Puritans knew nothing about railways, steam engines, telegraphy, telephones, the wiles of electricity, or of the Hawaiian question, and even escaped acquaintance with the A. S. M. E.; but they could paint their sheep sheds so thoroughly that the generations succeeding them have had but little to do in the form of renewals and repairs.

The *Engineering Journal*, Forney's, vol. 65, No. 4, page 163, April, 1891, has a long and instructive article on "The Preservation of Iron and Steel Structrual Work," by Woodruf Jones, A.M., that embodies so much useful imformation upon the subject of paint and its application to metallic surfaces, that I quote it almost entire in order to bring the best protective methods of the day down to a point for comparison: "The requisites of a good paint for the preservation of iron and steel are, that it shall adhere firmly to the surface and not chip or peel off; it must not corrode the iron, else the remedy may only aggravate the disease. It must form a surface hard enough to resist frictional influences, yet elastic enough to conform to the expansion and contraction of the metal by heat and cold. It must be impervious to and unaffected by moisture, atmospheric, and other influences to which the structure may be exposed. The paints that have been used for this purpose are principally asphalt and coal tar paints, consisting of mineral and artificial asphalt or coal tar, either applied alone or combined with each other, and more or less with metallic bases, and iron oxide paints and lead oxide paints, especially red lead, in all of which the pigment is held to the surface of the metal by combination with linseed oil. The choice of paints must lie, so far as our present practical experience goes, between these three classes, zinc oxide being found to be entirely unsuitable on account of its propensity to peel off. What then is found to be the experience in actual use with these? Asphalt and coal tar paints run when exposed to the sun and other sources of heat, which is a serious matter with vertical surfaces, and after a time become extremely brittle and scale off entirely, leaving the under surface exposed unless the paint is constantly renewed. In the mean time the exposed iron and steel are being corroded by rust. Iron oxide paints, including 'metallic brown,' are paints made from iron ore, or by some chemical process with an iron base. These are invariably iron in a greater or less degree of oxidation, or, in other words, rusted iron. Now, it is well known that one of the most active promoters of rust or decay in iron is the rust itself. Under the combined influences of the moisture and carbonic acid of the atmosphere, iron oxide, or iron rust, becomes a carrier of oxygen from the air to the metal, rust begetting rust; it is therefore evident that this material alone has no preserving effect on iron; in fact, it promotes its decay. How is it when combined with linseed oil in the form of paint? In the economy of nature iron oxide is a great disinfectant. When in contact with organic matter and moisture, even at a low temperature, under favourable conditions, it readily gives up oxygen, destroying, more or less, the organic matter, and being reduced itself to a lower oxide. When thus reduced, with equal readiness it absorbs oxygen from the atmosphere and again passes it on, thereby promoting and eventually ensuring the destruction or transformation of the organic matter with which it may be in contact either in the soil or elsewhere. The same process appears to take place when combined with linseed oil in the form of paint and exposed to atmospheric influences, the oil being the organic matter. If linseed oil in drying formed an air and waterproof film, it might be urged that the oxide of iron would be entirely protected from the direct influences of oxygen of the air and moisture; such, however, is not the case. The most eminent authorities have recently shown that the dried film of linseed oil, unless united with a pigment that combines chemically and forms a waterproof coating with it, actually absorbs water very much as a sponge. Where water will go, air will also go, and we thus have in direct contact with the iron oxide of the paint, which does not combine chemically with oil, those elements—air, moisture, and organic matter—which cause the iron to become a carrier of oxygen and a destroyer of what it is in contact with.

"It is well known that iron paint darkens with age; this is caused largely by the iron oxide losing oxygen, which is partly transferred to the oil, burning it up, and destroying its tenacity, as may be seen by examining iron structures painted for some time with iron paint or metallic brown, the paint being found extremely brittle and in feathery scales. This is not all the damage done. The iron oxide in the paint becomes a carrier of oxygen to the metal it was designed to protect, and the process of corrosion is commenced and carried on under the paint, which eventually peels off, the surface of the metal being found more or less oxidised and corroded. Asphalt and iron oxide being thus shown to be entirely incapable of preserving iron, it remains for us to consider the effect of red lead. This pigment has the property of forming with linseed oil a hard elastic coating clinging with great tenacity to the metal. It has no oxidising effect on iron, and does not act as a carrier of oxygen from the atmosphere after the paint has set, neither does it render the oil brittle nor promote rust. When red lead fails, it is principally by gradual wear or friction from the outside. It does not scale or blister, which both asphalt and iron oxide paints will do, thereby requiring a thorough scraping and removal of old material before a new coat can be applied. Any red lead pigment adhering to the metal forms a permanent base for subsequent paintings, and is utilised in further preserving the metal. The Government specifications for iron work in the new library building of Congress provide, that 'all the work not Bower-Barffed must be given one coat of pure red lead paint—not metallic paint of any kind, but pure red lead—before leaving the shop and before becoming rusted. The experiments of the Navy Department on the preservation and fouling of plates covered with different pigments may be interesting. A plate of iron covered with asphalt paint was immersed in sea water for eight months and six days. At the end of that period it was found to be covered with scum and mud and very badly pitted. A plate coated with iron paint was found to be covered with shell and coral, but little paint remained, and the plate was badly pitted and rusted. A plate with two coats of red lead was found to have a few barnacles attached, but to be in fair condition, with no rust whatever on the iron after the paint was removed. The red lead not only protected the iron better than the other pigments referred to, but the plates were in better condition as regards barnacles and fouling. The superiority of red lead being thus established, it is adopted for use on the hulls of all Government vessels. If red lead is thus proved to be the best pigment for preserving iron and steel structures, what is the best method of applying it? The value of red lead depends upon its forming a hard, elastic coating having a great tenacity for the metal. This is owing to its forming certain combinations with the oil, and actually setting very much the same as plaster of Paris or cement sets when mixed with water. To successfully work the latter substances it is necessary to put them in shape as quickly as possibly after mixing with water before setting takes place. If the chemical action of setting has partly taken place the material may be moulded, but good results will not be obtained. Red lead, like these substances, must be applied to the work before it sets with the oil. It is on this point that failures in the use of the pigment have generally occurred, because if it be applied after the combining or setting process has taken place the hard, elastic, clinging coating will not be formed on the metallic surface.

"The following is the practice of a large shipbuilding establishment in applying red lead to the hulls of vessels. The plates are first pickled in a dilute solution of muriatic acid, then passed through rapidly revolving wire brushes which remove all scale and dirt, leaving the plates with a bright surface; then are thoroughly washed with pure water and rubbed entirely dry, and immediately coated with red lead and raw linseed oil. The red lead is first thoroughly mixed with just enough linseed oil to form a very thick, tough paste, which will keep for several days without hardening. This paste, as wanted for use, is thinned down to the proper consistency for spreading with pure linseed oil, and applied at once; care being taken to leave the paint-pots empty at night. A gallon of paint thus prepared contains 5 lb. of oil and 18 lb. of red lead, and will cover on first coat about 500 square feet, the second coat about 600 square feet of surface. In this way the red lead and oil get their initial set on the surface of the metal, and the closer the pigment is brought to the metal the more durable will it be found. Iron primed with iron oxide or metallic brown paints before applying the red lead is a mistake, as these paints readily scale, and, of course, carries the red lead with it. Iron primed with oil before applying the red lead prevents the adhering paint from coming in contact directly with the metal, and should be avoided, because it is out of the question for it to hold on to the surface by any process of absorption into the pores of the metal. The rusting of iron before the application of paint, which is sometimes recommended, should by all means be avoided, as it not only prevents the contact of the paint with the metal, but induces a chemical action, which may go on with its corroding work under the applied paint, as referred to before. The application of dry lamp-black, an ounce to the pound of red lead, mixed together dry and before the oil is added, changes the colour to a deep chocolate, and prevents the red lead from taking its initial set with the linseed oil as quickly as when mixed with oil alone. This compound will remain mixed in a paste form for thirty days without hardening. If rapid drying is desired, Japan dryer can be mixed with the oil used in thinning the paste before application with the brush. The first cost of painting structures with iron oxide is less than with red lead; however, as the labour in painting structural work costs twice as much as the material, true economy must, therefore, be sought in the durability of the paint as well as the preservation of the structure from rust. Structures painted with iron paints have to be repainted the third or fourth year, and if the old material be entirely removed before applying the new coat in order to secure a good application, it entails an increased cost; whereas, with red lead applied at the end of the sixth year, no such expense is necessary, but as before stated, the portion of the pigment remaining on the metal continues to protect the surface, and is the best base for the new coat, and contributes materially toward it."

(*To be continued.*)

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

*Apparatus for coaling steamers.*—On the great lakes there is an enormous traffic in coal from Lake Erie ports to the North-west, averaging over 3,000,000 tons per season, and many of the coal steamers are of 3000 to 3500 tons. It is most desirable to handle the coal quickly without damage from breakage, and a large part of the work of loading is done by rotary derrick travelling buckets of five tons capacity, but even with these the largest vessels were delayed two to four days in loading, and with eight or ten men shovelling into buckets from a car 3ft. deep, and not taking more than 20 lb. at each shovelful, there was still the disadvantage of separating and breaking the coal. The McMyler apparatus recently put in service takes a loaded open coal car of 24 tons capacity, and dumps its contents at the mouth of the hatchway down a chute into the hold, so that the coal has practically no drop or fall. The dumping apparatus consists essentially of a car travelling on a track along the dock, and fitted with a turntable, steam engine, &c. At one end of the car is a plate girder "bridge" turning on a horizontal axis. The bridge is tilted to bring the shore end in line with the loading trucks, and a coal car is hauled upon it by a steel cable, the car being run to the opposite end of the bridge. The bridge is then tilted to bring the upper end down to the mouth of the hatch, the coal being discharged through the end of the car. All operations are effected by steam and hydraulic power. About thirty vessels have been loaded with 60,000 tons of coal in 300 hours.

*Electric locomotive.*—An electric locomotive, weighing 40 tons and having a draw-bar pull of 14,000 lb., has recently been built, and is designed for heavy hauling at speeds not over thirty miles per hour. The engine has an iron frame, with a large and roomy enclosed cab in the middle, and enclosed ends like the backs of two tenders. There is a headlight at each end, an engine bell, compressed air whistle, and air brake hose couplings. The engine is double-ended, having a pilot—or cowcatcher—coupler, and brake hose at each end. Upon the roof of the cab are mounted two trolley poles to bring the current from the overhead wires. The frame is carried upon two four-wheeled trucks or bogies, having frames of steel channels and plates. The wheels are 3ft. 4in. diameter, and the wheel base of each truck is 6ft., the total wheel base being about 15ft. The axle bearings are 4½in. diameter and 8in. long. Each axle is driven by a single-reduction spur gear motor, mounted upon the axle, as in street railway cars. The body or frame rests upon eight elliptical springs, which rest direct upon the axle-boxes, which arrangement secures steadiness and easy riding. The axle-boxes are of cast iron, with phosphor bronze bearings, and slide in jaws with adjustable shoes. The cab is of sheet iron, and contains, besides the controlling apparatus, an air compressor for the brakes. The engine is 24ft. long over the draw-bars, 11ft. 2in. high to top of cab, and 8ft. 4in. wide over all.

*Compound locomotives.*—The following table shows the performance of two consolidation engines—eight driving wheels and a two-wheel leading truck, of the same design, except that one is simple, with cylinders 19in. by 26in., and the other compound, 13in. and 21in. by 26in., in similar service, hauling the same train alternately for the twelve months ending June 1st, 1894. The compound shows a fuel economy of 15 per cent. in the three years of regular daily service, so that all exceptional results are eliminated in the general average:—

| | Simple. | Compound. |
|---|---|---|
| Miles run | 28,629 | 30,210 |
| Coal consumption, tons | 1,594 | 1,484 |
| Lubricating oil, quarts | 607 | 733 |
| Valve oil, quarts | 308 | 502 |
| Waste, pounds | 315 | 344 |
| Miles run per ton of coal | 18 | 20½ |
| Miles run per quart of lubricating oil | 47 | 41 |
| Miles run per quart of valve oil | 93 | 60 |
| Cost of repairs, dollars | 1,359 | 1,046 |
| Cost of fuel, dollars | 2,028 | 1,866 |
| Cost of oil and waste, dollars | 107 | 131 |
| Wages of enginemen, firemen, and wipers, dollars | 1,878 | 1,848 |
| Total expenses of engines, dollars | 5,372 | 4,890 |
| Cost per mile for repairs, dollars | ·475 | ·346 |
| Cost per mile for fuel, dollars | ·708 | ·617 |
| Cost per mile for oil and waste, dollars | ·37 | ·43 |
| Cost per mile run for wages, dollars | ·656 | ·612 |
| Total cost per mile run, dollars | 1·76 | 1·6 |

*Pneumatic dynamite guns.*—The Ordnance and Fortification Boards of the United States Government have recently been making extensive tests of the three 15in. pneumatic dynamite guns for the coast defence at Sandy Hook. The guns are placed in mortar pits, with heavy concrete walls banked with earth. In one test a projectile, weighing 1160 lb. and carrying 500 lb. of nitro-gelatine, was thrown 2400 yards, or one and a-quarter miles and exploded. The cap was set for two seconds after striking the water, and it was calculated that the projectile would be 18ft. under water at the time of explosion. An immense body of water was lifted from 100ft. to 300ft. in the air. This is the largest charge of high explosive ever used under similar conditions; charges of 100 lb., 200 lb., and 300 lb. were also fired and exploded. In the test for rapidity of fire, dummy projectiles were used, made of iron cylinders filled with sand. Each of the first five shots weighed 445 lb., and they were all discharged in 8 min. 45 sec., the contract time being 10 min. Each of the second lot of ten projectiles weighed 556 lb., and these were fired in 14 min. 40 sec.; contract time, 27 min. The third lot of ten projectiles weighed 1140 lb., the full charge, and the firing time was 15 min. 36 sec.; contract time, 40 min. The firing time for the twenty-five shots was 39 min. 1 sec., while the aggregate contract time was 77 min. The final tests for accuracy and rapidity of fire with these pneumatic-dynamite projectiles took place on August 24th. According to the contract the gunner had to land 74 per cent. of the projectiles within a space 30 yards wide by 120 yards long, at 2000 yards range. Five shells loaded with 500 lb. each of nitro-gelatine were landed all on a straight line only 39 yards long. The official firing time, from the order given to load, was 17 sec., 16⅓ sec., 17 sec., 17⅓ sec., and 17⅓ sec. for the five shots respectively. The first projectile, with a two-second fuse, struck the water and went about 150ft. before it exploded, when it threw up a great body of water. The heavy shells wabbled somewhat at times, and the second and third shots struck on their sides and exploded at the surface on impact; but the effect was described as terrific, sending a column of water 200ft. high. The third and fourth shots were perfect. Afterwards five dummy projectiles, weighing 1160 lb. each, were fired in 7 min. 58 sec., the contract time being 40 min. They were only thrown a few hundred yards, however, as the test was for rapidity of fire and not for range. The record made by the guns is so good that their acceptance by the Government is fully expected. The Government is to pay 162,000 dols. for the two 15in. and one 8in. pneumatic gun, with their carriages, electrical appliances, engines and air compressing machinery, dynamite magazines and air storage reservoirs. The wabbling of the big shells is said to be a defect easily remedied. The guns and carriages weigh 52 tons each, and are easily handled by one man, being controlled by electrical power.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

"Go slow," as the Americans say, is this week's motto in the Midland iron and steel trades. In one or two departments sellers have been "jumping" quotations, notably in Midland pigs, for which from 1s. 6d. to 2s. per ton extra has been asked. But any attempt to force the market beyond legitimate limits is deprecated by men of experience as likely to result in a recoil. Wherefore pig iron prices continue for the most part to rule at the figures given last week; though there is certainly more disposition on the part of buyers to operate ahead of consumption.

Does steel for galvanising answer, after all, better than iron? The discussion afresh of this question has been taken up in Midland circles this week. The opinion expressed in some quarters is, that those ironmasters who have lately been substituting steel for iron in the manufacture of galvanised sheets have quite as much as they can do to make the steel sheets a success. It is quite possible therefore that an increased number of forges for puddled iron will be employed in the future—rather than fewer—by those makers who have given the newer material a fair trial for this particular service. Galvanised corrugated sheets, doubles, are £9 15s. to £10, f.o.b. Liverpool; and £9 17s. 6d. to £10 2s. 6d. delivered London. Black doubles are £6 12s. 6d. to £6 15s.; lattens, £7 5s. to £7 7s. 6d.; and singles, £6 10s. to £6 12s. 6d.

Midland manufacturers are in receipt of colonial advices showing that the recovery of Australia's purchasing powers is proceeding satisfactorily. The financial condition of Sydney and of New South Wales generally is declared to be sounder. As compared with the corresponding period of last year, the failures in the Colony for the first half of the present year show a diminution of over 50 per cent. In Adelaide stocks of fencing wire, galvanised sheets, and wire netting were so cleared out a few weeks back that storekeepers could not fill customers' orders. Mining tools and station requisites have been the chief features in demand at Melbourne, whilst fencing wire, owing to the limited stocks, has advanced in price. The prospects of Western Australia in mining affairs are characterised as most hopeful, and considerable orders for mining machinery and tools may be expected to reach England within the next few months.

How far the proposed new Victorian Tariff, if it becomes law, will affect trade between the Midlands and that Colony remains to be seen, but it certainly ought to improve business to some extent, since machine tools are to be reduced from 35 per cent. to 20 per cent.; leather belting from 45 per cent. to 35 per cent.; whilst iron and steel horse nails are to pay a duty of 10 per cent. *ad valorem*, which is considerably less than the old impost. Proportionate reductions are proposed upon other leading classes of hardware also.

Messrs. Henry Lea and Thornbery, civil engineers, of Birmingham, have designed, and the Walsall Electrical Company have carried out, the installation of the electric light at the Birmingham market hall, which it is anticipated will be in actual use in about a fortnight's time. The annual cost of running the electric lamps will be £507 for energy and £25 for carbons, as compared with £522 for gas. It is proposed, however, to pay off the capital outlay of £900 in ten years, making an addition for interest and sinking fund of £100 per annum for the period named. The electric energy will be taken from the Electric Supply Company's mains.

The corporation considered the desirability of establishing their own generating plant, but decided not to do so.

Electrical engineering does not appear to be prospering just at present at Wolverhampton. The Electric Construction Company, of Bushbury, at its annual meeting had not been able to declare any dividend for the ordinary shareholders, but has spent £1819 in paying a 7 per cent. dividend on the preference shares. A profit of £15,764 has been made on sales of "shares and debentures of other companies," of which £12,500 is appropriated in reducing the amount at debit of that account. The amount carried forward to next account is £2260. Depression in trade and the interruption to business caused by the reorganisation of the company and its staff were adduced by Sir Daniel Cooper—chairman—as the reasons for the present position.

## NOTES FROM LANCASHIRE.

(*From our own Correspondent.*)

*Manchester*.—The recent improvement in the iron trade of this district is being well maintained. Although the weight of actual buying going on has fallen off considerably, prices continue strong at the advanced rates, and a more hopeful tone prevails as to the future. The improvement that has taken place is, however, still chiefly confined to pig iron, in which a fairly large business has been done. Manufactured iron has not, so far, participated to any appreciable extent in the increased demand, and the position in the steel trade is scarcely better to any material extent, beyond the increased business that has been thrown into the hands of local and district manufacturers by the stoppage of production in Scotland. With regard to the engineering industries there is still no really noticeable move towards improvement. Here and there special machine tool makers are able to report rather more work giving out, and in other branches there are isolated cases of increased activity, but generally the position remains but very unsatisfactory, with new work still coming forward but slowly, and in small quantities.

A fairly healthy tone would seem to prevail generally on the Manchester Iron Exchange on Tuesday, with a moderate weight of inquiry stirring and prices strong at full rates. For pig iron, although there is a considerable falling off in the weight of buying—as compared with a week or so back—there is still a moderate business coming forward, and at a trifle under their quoted rates makers could book fair orders here and there. For Lancashire pig iron makers still quote on the basis of 40s. for forge to 42s. for foundry, less 2½, at the works; or, equal to about 44s. 6d. for forge to 45s. for foundry, less 2½, delivered Manchester, and a limited business is being done at about these figures. For district brands, makers who are well sold for the present have in some instances hardened up their prices; but in Lincolnshire forge there are still low sellers, and business has been put through at about 39s. to 39s. 6d. net cash, delivered Manchester. The leading makers, however, do not quote anything under 40s. for forge, with foundry qualities averaging 41s. to 41s. 6d. net cash, delivered here. The Derbyshire makers are also further slightly stiffer in their prices, 45s. 6d. to 46s. net cash being now about the average quotation for good foundry qualities, delivered Manchester. Outside brands offering here fully maintain late rates, good foundry Middlesbrough being scarcely obtainable under 45s. 4d. net cash, delivered Manchester, whilst holders of Scotch iron are indifferent about selling under 49s. for Eglinton, and 51s. for Glengarnock, net prompt cash, delivered at the Lancashire ports.

Finished iron makers here and there are perhaps better off for work, but except that they are now able to take a firmer stand with regard to their quoted rates, there is no really material improvement in this branch of trade. Lancashire and North Staffordshire bars are not now quoted under £5 7s. 6d. to £5 10s.; Lancashire and Staffordshire sheets, £7 to £7 5s.; with the Association list rates for hoops remaining at £5 17s. 6d. for random, and £6 2s. 6d. for special cut lengths, delivered Manchester or Liverpool.

Nut and bolt makers report rather more business coming forward, but they are obliged to take rather low prices to get hold of orders.

In the steel trade the position is perhaps slightly better, and good foundry hematites are firm at 53s. less 2½ as the minimum for delivery in this district, whilst one or two makers who are well sold are asking quite 1s. per ton above this figure. Ordinary basic billets can, however, still be bought at £4 net cash, delivered here. For manufactured steel prices are firm at about £6 7s. 6d. to £6 10s. for boiler plates, and £6 to £6 2s. 6d. for steel bars for prompt delivery in this district, but there are forward sellers at under these figures.

In the metal market there is very little doing, buyers holding back in the expectation that the downward movement in raw material may bring a return to lower quotations for manufactured goods.

I had an opportunity of witnessing during the week, at the Botanical Gardens, a trial of a steam lawn mower—Sumners' patent—which is being introduced by the Stott Distributor Company, Manchester. This steam mower, which is combined with a roller, is a very handy machine, suitable for cricket and tennis grounds or large lawns, and consists of a boiler and engine mounted on the top of a roller, carrying in front an ordinary cylindrical cutter and grass-box, and the weight being so balanced that the machine can be controlled and directed by hand almost as readily as an ordinary lawn mower. The boiler is of the multitubular type, containing sixty-six copper tubes in a copper fire-box, the shell being made of mild steel. Steam is generated in the boiler by the use of ordinary lamp oil as fuel, which is burnt in the fire-box by a burner similar to that in a naphtha lamp. The oil is carried in a specially constructed reservoir at the top of the chimney, from which it is fed to the burner by a small tube, and the water is carried in a cylinder between the shafts of the machine. The steam pressure is regulated by a diaphragm, which automatically controls the supply of oil to the burner, so that the steam is maintained at a uniform pressure whilst the engine is working. The machine is made in various sizes from 20in. up to 42in. cutters, the one tried, which had 30in. cutters, being readily manipulated even by an inexperienced person. In addition to being used as a steam mower and roller, this apparatus also forms a small portable engine for driving any kind of light machinery, such as chaff-cutters, laundry, churning, and pumping appliances, small lathes, or dynamos for electric lighting.

The members of the Manchester Association of Engineers closed their summer excursions by a visit on Thursday last to the works of the Lancashire Watch Company, at Prescot, which had been kindly thrown open for inspection by Mr. T. P. Hewitt, the managing director. As these works were fully described recently during the visit of the Institution of Mechanical Engineers, it is unnecessary to again enter into details as to their general arrangement, but I may add that the opportunity afforded for the examination of a large number of specially-designed machine tools for performing the minutest possible work, with the greatest accuracy was, from a mechanical point of view, of exceptional interest to the members. After spending several hours in the works, the party sat down to tea at the Royal Hotel, Prescot, and Mr. Thomas Daniels, president of the Association, in giving expression to the great pleasure the members had experienced in going over the works, said that from what they had seen he was sure the company would be able to hold its own with any country in the world in the manufacture of watches. The mechanical ingenuity which had been displayed in developing and perfecting the machinery required for the various processes in the manufacture of watches was something surprising, and the highest credit was due to the management for what had been accomplished in this direction. Mr. Thomas Ashbury, C.E., then proposed a vote of thanks to Mr. T. P. Hewitt and the other directors. It had been said that genius was the perfection of detail, and an opportunity had been afforded them of seeing the perfection of detail carried out to a surprising degree, in the machinery which had been put down in the works for the various special processes in the manufacture of watches, and he was sure the members could not fail to appreciate the wonderful ingenuity which had been shown in designing many of the marvellous machines they had seen that day. Mr. Webb, in seconding the vote of thanks, said he did not know which to admire most—whether the perfect accuracy of the automatic machines, or the skill of those engaged in manipulating the various processes. Mr. T. P. Hewitt, managing director of the company, in briefly responding, said they had a great many difficulties to contend with in establishing the Prescot Watch Factory. Perhaps not the least of them was the prejudice which existed against machine-made watches. They had, however, been able to show that it was possible to produce watches by machinery which were quite as good as—if not better than—those made by hand, whilst the cost of manufacture had been enormously lessened. Operations which under the old process entailed a cost of 12s. up to 20s., were now being performed with perhaps greater accuracy at the cost of a few pence.

The coal trade continues exceedingly quiet, there being no move towards improvement, except perhaps a slightly increased inquiry for house-fire qualities. Pits are still not working more than four days per week, with the output considerably in excess of requirements. Common round coals for steam and forge purposes and engine classes of fuel continue more or less a drug in the market, and with the collapse of the Scotch strike, and the consequent cessation of the large shipments of coal for the above district, there is a probability of still further surplus supplies coming upon the market, which must necessarily tend to weaken prices, and the outlook as to the future is anything but encouraging. Quoted rates remain much as last given, averaging about 11s. for best Wigan Arley, 10s. for Pemberton four-foot and seconds Arley, 8s. for house coals, 7s. to 7s. 6d. for steam and forge coal, with engine fuel ranging from about 3s. 6d. to 4s. for common slack, to 4s. 6d. and 5s. for good medium, up to 5s. 6d. and 6s. for the best qualities, at the pit mouth.

In the shipping trade there has been a decided quieting down during the last few days, but quoted rates for Lancashire steam coal so far remain without any material change, averaging 8s. 6d. to 9s. per ton, delivered at the Garston Docks or the High Level, Liverpool.

*Barrow*.—There is a quiet business doing in hematite pig iron, and orders are not likely to increase. The foreign, colonial, and continental trade is very quiet, but there is still a fair business done on local account. Although the actual home demand and aggregate is small, makers are still quoting 45s. to 46d. net f.o.b. for parcels of Mixed Bessemer Nos., while warrant iron remains steady at 45s. sellers, and 44s. 11d. buyers, net cash. Stocks of iron are 257 less than last week, and now stand at 158,066 tons in warrant stores, or 63,443 tons less than in the beginning of the year.

Iron ore is quiet in tone, and orders are coming to hand slowly from all sources. There is very little doing on local account, and orders from Scotland are fewer than ever. Ordinary qualities are quoted at 8s. 6d. per ton net at mines, and best descriptions run up to 12s. and 13s. 6d.

The steel trade shows rather more life in tin-plate bars, and orders are coming to hand with more freedom. But in rails there is nothing new to report in the way of new business, although inquiries have increased, as is usual in autumn, and it is probable that a fair business will be done during the winter months. There is a brisk business at the steel plate mills, and although orders are not so plentiful as they have been, makers have reason to expect a continuance of briskness for several months to come. A quiet demand is experienced for billets and hoops, and no trade is doing in slabs, blooms, and wire rods.

Shipbuilders and marine engineers are fairly well employed, but new work is not coming to hand, and some orders which were expected have gone past. There is some prospect of new work, however, although it will only represent a small trade. Only a few repair jobs are now to hand.

Coal and coke are quiet at late prices. The consumption is small and is not increasing. Prices are steady.

Shipments are very unsatisfactory. The exports of pig iron for past week amounted to 3513 tons, and of steel 6605 tons from West Coast ports, compared with 2110 tons of pig iron and 8636 tons of steel during the corresponding week of last year, being an increase of 1403 tons of pig iron, and a decrease of 2031 tons of steel. The aggregate shipments for the year so far as it has gone represent 254,061 tons of pig iron, and 283,343 tons of steel, compared with 190,111 tons of pig iron, and 355,846 tons of steel in the corresponding period of last year, an increase of 63,950 tons of pig iron, and a decrease of 72,521 tons of steel.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE Doncaster week is mainly a holiday in the Yorkshire coalfield, particularly in South Yorkshire. All Yorkshiremen are "horsey," and the collier is the "horsiest" of all. The Leger Day to him is sacred, and as a rule he does little more work that week. The cessation of the coal traffic on the district railways is rather a relief to the companies; for the passenger trains are so numerous, and require so much attention, that minerals are in danger of being delayed or postponed in their dispatch. On Wednesday very few agents or buyers were at Barnsley, and it was somewhat unusual to find any there on Leger Day. It was stated that, contrary to the custom of previous years, several pits were working; and this may be the beginning of a new order of things, when the collier will take more interest in his work than in his pleasure in Leger week. Other circumstances combined to make last week a dull time in the coalfield. The dispute with the pit lads is not yet settled; and, in spite of the advice of the Yorkshire Miners' Association officials, the youths appear disposed to have a few days' "play." There is also a dispute with regard to the colliery enginemen. They resist the reduction of wages as decreed by the Conciliation Board on the ground that they are not members of that board, and that they are not bound by its decrees. They therefore demand that their minimum wages shall remain at 30 per cent. above the 1888 rates. A ballot of the enginemen has been taken, and the bulk of the papers are already received. A few have yet to be given in, and the time for receiving them has been extended until Saturday next. On the ballot paper they are required to say "Yes" or "No" to the question of a reduction, and further to say whether they will agree to give fourteen days' notice in the event of the reduction being enforced. A strike of the colliery enginemen in South Yorkshire would be a very serious factor in the autumn coal trade, for they practically hold the working in their hands. It is not anticipated, however, that the difficulty will lead to anything like a general rupture in the coalfield.

The demand for house coal is getting more active owing to the easterly winds causing householders to begin stocking for the winter. Summer prices will be maintained until the end of December, after which there will no doubt be an advance. At present Silkstones are making from 9s. 6d. to 11s. per ton, and are firm at the figure. Barnsley House from 8s. 6d. to 10s. per ton; other qualities about 8s. per ton. Steam coal is well called for, the reports of the export trade from Hull and other Humber ports still continuing favourable; prices vary from 8s. to 8s. 6d. per ton. It is noteworthy that although the Baltic trade, in the aggregate, is not quite up to former years, there has been a considerable increase in the weight taken by markets where a heavy trade was scarcely expected. These include Belgium, Germany, France, and several of the Mediterranean ports. Gas coal is rather firmer, but it is not ordered in anything like large quantities. The demand for slacks is affected by the depression in the manufacturing districts. Supplies are largely in excess of the demand, and good slack can be procured from 3s. 6d. to 4s. 6d. per ton. Smudge and small coal are practically unsaleable.

The steel trade does not exhibit any material alteration on the week. There is a brisk inquiry for the higher qualities of tool steel from the Continent, but the call for crucible steel generally is, if anything, weaker in that direction than during the earlier months of the year. On the whole, however, a slight improvement is apparent in business. Railway material scarcely maintains the animation reported a month ago, although several of our firms are well off for orders. The increased value of the rupee is an encouraging feature for India and other countries where a silver currency is in use. If it could be maintained after the termination of the war between China and Japan, business with India and similar markets would be immensely improved. Very little hope is entertained of the rupee remaining above the old figures when the present hostilities are at an end. A general stiffening of prices is reported in pig iron. Hematities are sold in Sheffield at 1s. to 1s. 6d. per ton advance upon the prices obtainable three or four weeks ago. Forge iron has gone up quite 2s. per ton. Hematites are 52s. to 54s. per ton, according to brand. Common forge iron, 39s. to 40s., both in Sheffield. Bessemer billets, £5 10s. to £5 15s. per ton.

Shipbuilding is exceedingly slack, and there are few signs of any improvement, freights indeed being lower than ever, and consequently there is no inducement for new vessels to be built. The P. and O. Company's recent orders for five ships—three with Messrs. Caird and Co., Greenock, one with Messrs. Alexander Stephen and Sons, Glasgow, and one with the Palmer Shipbuilding Company—are practically the only items of importance placed during the last few weeks. So long as a large number of ships is laid up for want of work, one cannot of course look for any improvement in that direction. The want of orders for shipbuilding material has brought the prices of steel plates and bars to a figure which can only leave the makers a loss, and although during the Scotch coal strike sixty-eight out of seventy furnaces in blast have been blown out, trade has been so bad that the absence of this large output has hardly affected the price of pig iron.

At the Cyclops—Cammell's—and River Don Works—Vickers'—armour-plates are being made for two first-class battleships now being built in this country for the Japanese Government. At the Atlas Works—Brown's—the boilers for both ships—eighty furnaces in all, of the Purves type—are being constructed.

The Duke of Cambridge visited the Cyclops Works—Messrs. Charles Cammell and Co.—last Saturday, the principal object of his Royal Highness's visit being to witness the testing of the Boynton shield. This shield is patented by Captain Francis Boynton of the staff of the Cyclops Works. The shield is a plate of specially prepared chrome steel, with a slot in the top for the soldier's rifle, which may be secured to an attachment. The weight is stated to be less than one-half that of a lifeguardsman's cuirass, and it is claimed that the material is absolutely proof against service bullets propelled by cordite through a Lee-Metford barrel at thirty yards distance. The experiments were conducted in a simple though effective manner. Six plates lay on a wooden trestle a few yards away from a tube thirty yards long constructed like a shooting gallery. Near an adjoining wall six shields were buckled together in order to illustrate the effectiveness in a campaign. In this position they resembled six riflemen. In another part of the works a rifleman lay prone with a shield on his head. This was intended to demonstrate the difficulty of any marksman hitting the soldier in a vulnerable spot, the protection at the same time not being so cumbrous as to prevent him assuming the offensive. One of the plates, after a chalked circle had been marked upon it, was fixed at the end of the gallery. Mr. Tucker, R.E., fired five shots from a Lee-Metford rifle, the marksman, by desire of the Commander-in-Chief, placing his shots as nearly as possible in the same spot. Four of the bullets struck the plate within a circle little more than an inch in diameter. The only sign of the impact was a slight tearing of the steel in the rear of the bulge caused by the repeated blows on the same spot. The plate, however, remained entirely unperforated. Each bullet was estimated to strike the shield with more than a foot ton of energy. After the trials his Royal Highness expressed his perfect satisfaction at the results of the tests, as not the slightest damage appeared to have been done to the shield. Messrs. Cammell and Company had, he considered, succeeded in solving a problem which had baffled the experts for many years. The tests were undoubtedly striking testimony to the superior quality of the metal employed, and in his opinion the result of the firing was eminently satisfactory. The Commander-in-Chief had an opportunity of seeing other processes in the works, including the casting of a 52-ton ingot, which, when reduced to the necessary dimensions, will form part of the armour of H.M.S. Magnificent. The hydraulic press of the firm, which exercises a pressure of 6000 tons, was also seen in operation. His Royal Highness likewise witnessed the cutting of both large and small files, the reducing of steel ingots to wire, the preparation of spring steel for use in railway carriages, and other processes. Before leaving the works the Commander-in-Chief expressed the pleasure which his visit had afforded him, and his astonishment at the marvellous operations that he had seen.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

BUSINESS has become quieter in some departments than it has been for some time past, but in others the improvement is fully maintained, and prices tend upwards, especially for pig iron. There is not much increase in the consumption locally of Cleveland pig iron, as the finished iron and steel works are really not much better off than they were in the summer, but a larger trade has recently been done in pigs for export, and during the last fortnight especially have the sales been heavy to Scotch consumers, who have been buying in anticipation of the termination of the miners' strike, as they expected higher prices to rule when that event occurred. The strike has virtually collapsed, and as the proprietors of the Scotch mills, forges, and foundries can now procure fuel, they have in many cases recommenced operations, but they are not able to secure at home all the pig iron they need, because all but two of the Scotch furnaces have been stopped, and will not be in a position to supply pig iron for some little time yet. Therefore that has to be obtained largely from Cleveland, and orders for considerable quantities have recently been given out, which have served to strengthen the market in this district, and will increase the shipments, which latterly have been disappointing, as was natural when the chief market outside the district for Cleveland iron had its consumption so greatly reduced by the labour troubles. It is expected, therefore, that the pig iron shipments from the Tees to Grangemouth for the rest of the month and for the early part of October will be much in excess of what they have been, and in addition to this merchants and consumers on the Continent will import more freely, as the navigation season will not last more than a few weeks longer. So far this month the pig iron exports from the Tees have been poor; up to Wednesday night they were only 46,125 tons, against 42,665 tons last month, 57,775 tons in July, and 58,855 tons in September last year, all to 19th. As the production has not been at all reduced, but has rather been increased by the blowing in of another furnace in the Middlesbrough district, there can be no doubt that up to the present stocks will have been increasing, more especially of hematite pig iron, the makers of which find their position anything but satisfactory, as they are able to get but a very small increase in their prices, and the cost of production is rising, owing to the advance that is being demanded in the price of foreign ore, particularly Rubio, which is now not less than 12s. per ton delivered at Tees-side furnaces, and more is generally quoted.

A good deal of No. 3 Cleveland pig iron has this week been sold at 36s. 6d. per ton for prompt f.o.b. delivery. Some firms have been able to realise 36s. 9d., and others even 37s. The demand is chiefly confined to iron for early delivery, the disposition to buy forward having disappeared, as many believe that after the Scotch furnaces get to work again the value of pig iron will become easier. Till then it may advance, and some people expect to see 37s. generally realised this month. No. 1 g.m.b. is sold at 38s. 6d., No. 4 foundry at 35s. 6d., No. 4 forge at 34s. 9d., mottled at 34s. 3d., and white at 33s. 9d., all for early delivery. Cleveland warrants have this week fluctuated more in price than usual, owing to speculative operations, but this has had little influence in the prices of makers' iron. Fluctuations in the prices of warrants must be looked for, as at intervals speculators proceed to realise, and such action depresses the value of warrants for a time. The stock of Cleveland pig iron in Connal's public warrant stores on Wednesday night amounted to 90,066 tons, or 323 tons decrease this month. The improvement in the value of East Coast hematite pig iron continues small, and prices have advanced very little. Most makers quote 43s. 3d. per ton for prompt f.o.b. deliveries of mixed numbers, but there have been sales at 43s.

The improvement in the finished iron and steel trades has not been so great as has generally been represented, and the endeavour of manufacturers to secure advanced prices has not been attended with much success. Quotations certainly were raised, but consumers generally were not prepared to pay them. The steel rail trade is very dull, and a large steel and iron company has not been able to avoid the closing of its works. It last Saturday stopped one section entirely, throwing two hundred hands out of employment. This week the large mill has been kept going, the steel necessary for the completion of orders being purchased from other firms. On Saturday, however, this mill employing 300 hands will be closed, leaving in operation only the small mills, employing 300 men, and the work in hand will only suffice to keep this department going two or three weeks more. No doubt the works are disadvantageously situated when compared with the establishments nearer the seaboard for the manufacture of rails. The pig iron alone will cost 2s. 5d. per ton more for carriage, and then there is the cost of the carriage of the finished material to the shipping place, as nearly all the rails are wanted for export. It is not a matter of surprise, therefore, that the Works cannot compete successfully with those which can secure cheaper materials and have superior shipping facilities. These other rail mills are fairly well employed, and the price of heavy steel rails is about £3 12s. 6d. net per ton at works.

The plate and angle makers find the demand very quiet, but that is only what might be expected when the dulness in the shipbuilding industry generally is taken into account. This is not a time to order new vessels, when so many of those already built are laid up, and many of those that are running are doing so at a loss. On the Tyne alone fifty-seven steamers are laid up, and if this is the case in what is usually a busy period of the navigation season, the outlook for the winter is not encouraging. A good many yards have vacant berths, but the leading yard on the Tees, that of Sir Raylton Dixon, appears to be well situated, as they have five large steamers on the stocks in various stages of construction, besides three which are waiting for engines, and the keel of a China tea steamer of about 6000 tons is to be laid down in the berth of a steamer launched this week. On the Tyne work is interfered with by the strike of shipyard apprentices. The pattern-makers are still on strike, and refuse to have their dispute settled by arbitration, or to abate one jot from their original demands. Their action, however, does not interfere much with trade. The engineers are being set to work as rapidly as it can be found for them, but there are still more than 10 per cent. of the engineers idle. Ironfounders are doing better, though not as well as they expected, and some of the bridge-builders find business rather brisker. The bridge work required for the extension of the North-Eastern Railway from Annfield Plain to Consett will be executed by the Stockton Forge Company.

At the annual meeting of the shareholders of Sir W. G. Armstrong, Mitchell, and Co., Elswick and Low Walker, the directors will recommend a dividend of 10¾ per cent. per annum, as against 10 per cent. last year, 9½ per cent. in 1892. For the last eight years the average dividend has been 10⅝ per cent. Since the announcement the £100 shares of the company have gone up from 162 to 173. The profit on last year's operations was over £230,000. The directors say that the Elswick Works, though not so fully employed as they could wish, has a considerable number of orders on hand. They did not suffer so much from the long strike of moulders and pattern-makers as might have been anticipated. The works at Pozzuoli, near Naples, are well employed, and have during the year been turning out excellent work, while they have a sufficiency of orders on hand to keep them occupied during the current year.

The coal trade both in Northumberland and Durham is animated, and the production fully as heavy as it was last month, though it is expected that it will fall off somewhat now that the colliers in Scotland are resuming operations. Not more than 1 per cent. of the colliers in these two counties are returned as out of work, and that those employed have regular work is shown by the fact that the colliers are running 10¾ days per fortnight in Northumberland. Deliveries on export account are increasing, as continental merchants and consumers want supplies before the Northern navigation season closes. The price of best steam coal ranges from 10s. 6d. to 11s. per ton f.o.b. Blast furnace coke is strong at 12s. 6d. per ton delivered on Teesside. The Northumberland miners' representatives are going to discuss with the masters the question of reducing the hours of boys in their mines. The men work only seven hours per day, but the boys are employed ten hours daily. The wages of colliery enginemen in Northumberland have been reduced 2d. per day, and of firemen 1d., making winding enginemen 4s. 8d., hauling and pumping enginemen 4s. 7d., and firemen 4s. 0½d.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE has been a good deal of activity in the pig iron market, mainly in Scotch warrants, the prices of which, although irregular, have on the whole been rather higher than last week. It is believed that the expected termination of the miners' strike has led to a good deal of speculative business. Be this as it may, consumers have as yet little inducement to purchase. The state of trade is very unsatisfactory, and the prospect is that there will be no lack of iron so soon as the furnaces are set going. For Cleveland iron there is very little demand. Hematite warrants have, however, been more in request.

The values of makers' iron are well maintained. G.M.B. f.o.b. at Glasgow, No. 1, is quoted 45s. 6d. per ton; No. 3, 44s.; Monkland, No. 1, 48s.; No. 3, 44s.; Carnbroe, No. 1, 48s.; No. 3, 46s. 6d.; Calder, No. 1, 58s. 6d.; No. 3, 50s. 6d.; Summerlee, No. 1, 58s. 6d.; No. 3, 52s.; Coltness, No. 1, 59s.; No. 3, 52s.; Glengarnock at Ardrossan, No. 1, 54s.; No. 3, 49s. 6d.; Eglinton, No. 1, 54s. 6d.; No. 3, 48s; Dalmellington at Ayr, No. 1, 50s.; No. 3, 49s.; Shotts at Leith, No. 1, 59s. 6d.; No. 3, 52s.

The output of pig iron consists of the produce of only two furnaces, which are in operation at Coltness. There is so far scarcely any sign of preparation for re-starting furnaces, but as soon as the strike is really over the ironmasters will gradually light up a considerable proportion of the furnaces now idle.

The demand for pig iron for shipment is very quiet. The shipments in the past week amount to 2263 tons, compared with 5568 in the corresponding week of last year. There was sent to Russia, 1000 tons; Australia, 250; Canada, 200; United States, 25; France, 20; Italy, 50; Germany, 40; Belgium, 10; Spain, 86; the quantity sent coastwise being 582, against 1499 in the same week of 1893.

The market for malleable iron and steel continues very quiet. The home inquiry is easily met, and the exports are much below the average. Two or three malleable ironworks have started and are doing a little, but some weeks must yet elapse before work can be anything like general. The steel works are still closed as regards the greater part of their manufacture, only a few men being engaged at special jobs which could not be deferred.

The shipments from Glasgow of iron and steel manufactured goods in the past week embraced locomotives worth £7460, sewing machines £4928, other machinery £1662, steel goods £6719, and miscellaneous iron goods £12,593.

The miners' strike is gradually coming to an end in the West of Scotland. Neither the leaders nor the men themselves appear now to have any hope of the employers making the least concession in the matter of wages. What they are contending for in some districts is a guarantee that wages will not be further reduced for a given period, and that the masters agree to the formation of a conciliation board. The connection of the miners with the English Federation is regarded by the employers as having rendered conciliation impossible. There is nothing to induce the masters to make any concession. They have themselves suffered severely during the prolonged struggle, and the state of trade does not hold out any prospect of activity.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

I AM very sorry to learn that there is a strong likelihood of a coal strike on a large scale in 1895.

One of the influential colliers, a man superior to the haulier class, which is chiefly composed of young and impulsive men, assures me that the principal colliers are almost decided upon giving in notices to terminate the sliding scale. This, he expects, will be done next month, and by the time the notice is matured we shall be in the summer, he said, a more preferable time for fighting than in the winter.

We do not, he continued, intend to join the Miners' Federation, for our coal trade and that of England are radically different. The English trade is a home trade, ours a sea or export one. What we wish to do is to get up a strong union amongst ourselves, and amend the sliding scale. He assured me that a large number of fellow workmen had implicit faith in the principle of the sliding scale, for which they are indebted to Sir W. T. Lewis, though the belief was that some changes were needed to give full satisfaction. So the Welsh coalowners and the country have to look forward to another labour upset. As one of them remarked, they must bear it with equanimity. "It seems in the order of things that we should have a periodical upset.'

At present the demand for best steam coal continues to be very marked. Last week the coal exports from Cardiff, including the Bute, Barry, and Penarth, exceeded 313,000 tons. House coal, too, continues firm in price, and the demand good, and coalowners in the house trade have the satisfaction of knowing that they are on the borders of their "season," with fair prices that will assure contracts being entered into at moderately good prices.

The latest quotations, Cardiff, for all sorts of coal were this week as follows:—Best steam 11s. 9d. to 12s.; seconds, 11s. to 11s. 6d.; dry sorts, 10s. to 10s. 3d.; small, 5s. 6d. to 6s.; best house, 11s.; No. 3 Rhondda, 10s. 3d. to 10s. 6d.; brush, 8s. 6d.; small, 6s. 6d.; No. 2 Rhondda, 8s. 9d.; through, 7s.; small, 4s. 9d. to 5s.

Coke continues in improved demand, and prices show a slight change for the better. Latest Cardiff prices are:—Furnace, 15s. to 16s.; foundry, 17s. to 17s. 6d.; best, 20s. to 20s. 6d. Swansea prices:—Furnace, 12s. to 12s. 6d.; foundry, 17s. 6d. to 18s. cash; thirty days less 2½.

Other Cardiff quotations this week are:—Pitwood, brisk, 15s. 6d.; patent fuel unchanged. Swansea: 10s. 6d. to 11s., moderate export.

There is a better tone in the iron and steel trade, and more inquiry for rails. 200 tons were despatched to Paysendu this week. For steel sleepers there is a large demand from Africa and the East Indies, and the prospects of a larger tin bar trade are now certain, though the North is doing its best to get a share. This week there has been a large quantity received from Harrington, and I have noticed a considerable increase at the various sidings of the steel works.

Latest Swansea quotations generally are this week:—Glasgow pig, 43s. 11d., cash buyers; Middlesbrough, 36s. 6½d.; Middlesbrough hematite, 43s. 7d.; Welsh bars, £5 to £5 2s. 6d.; sheet iron, £6 to £6 10s.; sheet steel, £6 5s. to £6 10s.; steel rails, £3 15s. to £3 17s. 6d., heavy; light, £4 10s. to £4 15s., Bessemer steel, tin-plate bars, £4 to £4 2s. 6d.; Siemens best, £4 2s. 6d. to £4 5s., all delivered in the district, cash less 2½. Block tin, £73 2s. 6d. to £73 5s. There is a rumour that a "corner" is forming, which would certainly be followed by higher prices.

Swansea anthracite quotations, latest, are:—Best big vein, 12s. to 12s. 6d.; second quality, 10s. to 10s. 6d.; ordinary large, 8s. 9d. to 9s. 6d.; small, 4s. 9d. to 5s.; iron ores, Rubio, 11s. 3d. to 12s.; Tafna, 11s.; specially selected Rubio, 1s. 6d. extra.

The latest report from tin-plate centres is that inquiries are increasing, and there is a great deal more animation exhibited; but, so far, stocks have shown more accumulation. Last week, owing to non-arrival of tonnage, the export was only a little over 41,000 boxes; while 66,426 boxes were received into stock. The total stock is now reported to be higher than at any other period—338,126 boxes. A marked diminution may be expected to be shown next week, as no less than eleven steamers are due in; seven from the United States and Canada. A good shipment has taken place of late from Batoum and Russia. It is also encouraging to note tinned ware is getting more common, and a larger variety of uses found; and the opinion is growing strong that china and earthenware industries will suffer, while our steelmakers will get the benefit. One complaint has been received which will suggest a corrective by the inventive mind. This complaint is, that for cups, water jugs, &c., the hot water so affects the handles that it is difficult to hold them. Tin-plate quotations remain with upward tendency. I visited this week a great track of the Cambrian Railway, and noted the excellence of the arrangements by which great connections, Hereford at the Three Cocks, Newport, Mon., at Partsticill, and Cardiff at Merthyr, are linked with Aberystwith and North Walian resorts. The express arrangements have been worked very satisfactorily, and the corridor carriages answer well. In all respects, passenger and goods, the season has been a satisfactory one, and the administration of Mr. Aslett all that could be desired. There are, however, still developments that are required of North Wales industries to make the line more remunerative. The gold "boom" yet lingers at Dolgelly, and I am sorry to hear that Mr. Pritchard Morgan is seriously indisposed. The development of the rich tracts of manganiferous ores from Dolgelly to Harlech is yet in the future as regards any appreciable extent.

I have also visited this week the Birmingham Waterworks area, near Rhayader, in the Elan and Nantgwilt Valleys. So far the case is one of preparations. Quite a township of huts has been erected; a railway constructed that one would have thought might have been straighter, trees felled, the mountain side scarped, and the bed of the river broken up with a view to get a secure and a fissureless foundation. The latter point is one of marked importance. At Merthyr Tydvil the formation of a reservoir at Dolygaer on a bed of carboniferous limestone—notably full of fissures—has cost many thousand pounds sterling. The chief engineer of the works near Rhayader resides at Nantgwilt, famous as the residence, at one time, of Shelley, the poet. Here, as at the Vyrnwy, the Liverpool watershed, a graveyard is to be submerged.

Cardiff new docks, the great task for the next ten years, but of which, if I am not much mistaken, we shall see practical issues in less than five, are now more than limned out on plans. The site is now very perceptible from Penarth grounds. The work of constructing the embankment is proceeding apace, and up to the present 3000 yards from the low-water pier have been made by the tipping of 100,000 tons of slag from the old tin and ironworks at Walnut Tree. The course adopted is to tip two parallel lines of slag, leaving a space for clay, in order to make a water-tight embankment. The foundation is tolerably solid, but the slag sinks into an average depth of 7ft., and the height of the embankment, including sinkage, is from 22ft. to 23ft. A local authority, to whom I am indebted for the description, states that as the slag sinks down the soft mud comes up between the two ridges, and thus assists in filling up the open space. At the base the embankment is 80ft. wide, and an enormous quantity of rubbish will be needed to make a bank extending from the end of the low-water pier to a point eastward of the Roath Dock. Sir W. T. Lewis is of opinion that this work can be done in twelve months, after which the construction of a dock proper will commence. The dock is to be 700ft. in length, so that mercantile vessels of about 100ft. longer than any afloat can be admitted.

Big steamers are increasing visibly.

Mr. Hedley, who has been called in by the Cardiff Corporation as an expert in connection with the Harbour Trust scheme, met Sir W. T. Lewis this week, as Lord Bute's agent, and had a conference. Several members of the Corporation were present, also Mr. Hunter, engineer of the Bute Docks, and Captain Pomeroy.

The coal trade of Newport is very brisk, and prospects good.

Harbour reports at Swansea are also eminently satisfactory. Last week was a marked improvement on the corresponding week of last year.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE general iron business over here has been showing a little more activity upon the week, and there have been some fairly good orders secured, but the prices makers had to accept were, in most cases, even more unfavourable than before. In some parts of Silesia the condition of the iron industry is reported to have slightly improved, but the greater part of the blast furnace works continue only very moderately employed. On the malleable iron market prices have become easier of late. There has been next to no business done in bars, and Breslau dealers were compelled to reduce the price for merchant bars on M. 120 p.t. at works. In girders and plates the demand coming forward is far from good. The steel trade as a rule is dull, though two or three firms have been rather fully employed upon the week.

Business transactions on the Austro-Hungarian iron market continue quite satisfactory. Pig iron is rather scarce, which is but natural, considering that this year's production in malleable iron has been about 20 per cent. higher than last year. For the different sorts of manufactured iron a regular and even lively inquiry has been coming forward, girders being the only article that has been a trifle dull lately. The railway and engineering department is briskly engaged. An order for 200 freight cars for the Warsaw-Vienna Railway has just been awarded to the Ringhofer Wagon Shops at Prague.

In France the industrial situation is still without improvement, and the works are but quietly engaged, but the general feeling is hopeful, as there are more orders expected to be given out before long, chiefly in girders and structural material. In Paris merchant bars are unchanged at 155f. p.t., girders fetching 165f. p.t.

No signs of revival are as yet to be found in the Belgian iron trade, and the position of both makers and manufacturers remains extremely unfavourable. Pig iron even shows a decrease in demand against former weeks; but fortunately, prices remain tolerably firm—and that is something, after the continued downward movement of the preceding months.

Rhenish-Westphalian iron business remains practically without improvement. Few purchases are made, both in raw and in finished iron; but in spite of this, makers report themselves even more content with the present demand than with the prices obtainable. In iron ore the business, at least in the Siegerland, has not been so lively as before: M. 7·40 to 7·70 p.t. is quoted for spathose iron ore; while for roasted ditto, M. 10·80 to 11·20 p.t. is given. Nassau red iron ore is paid with M. 9·20 p.t., free Dillenburg. In Luxemburg-Lorraine prices are, with few exceptions, pretty firm; red minette, 40 p.c. contents, is quoted M. 3·30 to 3·40 p.t., while for inferior qualities M. 2·40 to 2·60 p.t. is paid. The blast furnace works of the Siegerland are fairly well engaged, common forge being in regular demand at M. 44 p.t. Spiegeleisen is quiet at M. 52 p.t. for the 10 to 12 p.c. grade. For Rhenish-Westphalian forge pig No. 1 M. 46 to 47 p.t. is given; No. 3 costs M. 40 p.t. Hematite remains firm at M. 63; foundry No. 1 M. 63; No. 3 M. 54 p.t. Basic, M. 45 p.t.; German Bessemer, M. 49 to 50 p.t. Luxemburg forge pig continues to be quoted 48f. p.t. free Luxemburg. The different branches of the malleable iron trade are still remarkably quiet, and the condition of prices continues very unfavourable. In the bar trade small orders are coming to hand pretty freely, while large contracts are exceedingly scarce; prices remain very weak, with a good deal of low cutting in the open market. Up-to-date, stocks have been decreasing rather than otherwise. Girders are in moderate call. The hoop mills continue well employed on orders of previous date, and are, therefore, rather independent with regard to new work. The plate and sheet makers have been quite satisfactorily occupied recently, and there is generally a somewhat better tone prevailing in that department, although present list rates still leave no profit. The dulness in the wire trade is as great as ever; in fact, some manufacturers affirm that they have never known it so slack. Foundries and machine shops find it extremely difficult to meet with orders, and if they are fortunate enough to secure a contract, however trifling it may be, they generally have to make substantial concessions, so that there is every cause for complaints. A regular activity continues at the wagon shops.

Latest list quotations, per ton at works, are as under:—Good merchant bars, M. 105 to 110; angles, M. 120; girders, M. 90 to 95; hoops, M. 110 to 115; billets in basic and Bessemer, M. 81; heavy plates, for boiler-making purposes, M. 150; tank do. M. 130 to 135; steel plates, M. 125; tank do., M. 115 to 120; Siegen thin sheets, M. 130; in steel, M. 120. Iron wire rods, common quality, M. 115 to 120; drawn wire in iron or steel, M. 105 to 120; wire nails, M. 125; rivet iron, M. 130; rivets, M. 150; steel rails, M. 112 to 115; steel sleepers, M. 106; fish-plates, M. 115; complete sets of wheels and axles, M. 270 to 280; axles, M. 220; steel tires, M. 215 to 230; light section rails, M. 95.

The consumption of coal in Berlin was, for the first two quarters of 1894, in pit coal and coke, 739,539 t., + 47,702 t. against the same period last year, and in brown coal 321,946 t., – 72,270 t. against last year. Of the coal consumed, 94,894 t. came from England, + 4045 t. against previous year; 36,686 t. from Rheinland-Westphalia, – 1081 t. against last year; 501,654 t. from Upper Silesia, + 28,608 t. against last year; and 100,837 t. from Lower Silesia, + 14,043 t. against the corresponding period in previous year.

THE Midland Railway Company has commenced operations on its new line from Chapeltown to Barnsley. The line starts at a point in Whitewool, Chapeltown, at once enters a deep cutting passes over the Thorncliffe Viaduct, and then reaches, near Thorncliffe Works, a tunnel which will be the most important and expensive portion of the line. It will be 1496 yards in length and lined with blue bricks throughout. Five shafts, varying from 20 yards to 50 yards deep, are being put down from the surface to ventilate the tunnel. The new line will give the Midland Company ready access to the capital of the South Yorkshire coalfield. At present its route is by Cudworth, which is a long way round, being 22 miles against 17¾ miles. There is some idea that the new railway will ultimately be carried forward to Bradford, forming part of a new line to the North.

## LAUNCHES AND TRIAL TRIPS.

On Monday, 17th inst., Messrs. Lobnitz and Co., Renfrew, launched the twin-screw hopper dredger St. Dunstan, being the first of two dredgers they are building to the order of the British Admiralty. The dredger will be fitted by the builders with twin-screw engines and dredging machinery, to work easily to a depth of 45ft. below water.

On Monday afternoon, the 17th inst., the Blyth Shipbuilding Company launched from its shipbuilding and graving dock works at Blyth a screw steamer of the partial awning deck type, built to the order of Messrs. Stephens, Mawson, and Goss, of Cardiff and Newport. The framework of the vessel is composed of a very strong section of bulb angle, and web frames are fitted in lieu of hold beams. She has cellular double bottom throughout, and is generally built of exceptional strength, and with all the most up-to-date improvements suitable for a first-class cargo steamer. The captain and officers will have suitable accommodation under the poop, and the engineers are comfortably provided for at the after end of the bridge. The vessel has powerful steam winches to each hatch, Clarke, Chapman, and Co.'s windlass and patent donkey boiler, and Hastie's steam steering gear. The ceremony of naming the vessel Kirkwall was performed by Miss Lydia Stephens, daughter of the senior partner of the firm. The Kirkwall was towed to the North-Eastern Marine Engineering Co.'s works, Wallsend, where powerful triple-expansion engines will be fitted.

On Tuesday Messrs. Wm. Simons and Co. launched from their yard at Renfrew, complete with its dredgings and propelling machinery on board, the twin-screw hopper dredger St. Alban. It is the first of two hopper dredgers recently ordered from this firm by the Government, and the fifth hopper dredger they have constructed for the British Admiralty. The St. Alban is specially designed to dredge and discharge clay of very adhesive nature, and is capable of working to a depth of 46ft. under water. The latest improvements have been carried out in this vessel, and it is expected it will leave for Portsmouth in a few days, where it is to be employed. As the St. Alban left the ways the naming ceremony was performed by Mrs. Robert Crawford, of Greenock. At the launch there were present Messrs. Painter, Parker, and Scoggins, H.M. surveyors, under whose supervision the vessel was built; also Mr. Robert Crawford, harbour engineer, Greenock, and others.

On Monday afternoon, the 17th inst., there was launched from the Cleveland Dockyard of Sir Raylton Dixon and Company at Middlesbrough a very handsomely modelled steel screw steamer, which has been built to the order of Messrs. Elder, Dempster, and Company for the African Steamship Company, and which is intended to run with passengers, mails, and cargo between Antwerp and the Congo and other settlements on the West Coast of Africa. The decks will be of East India teak, and cabin accommodation of very handsome description will be fitted for ninety first-class and sixty second-class passengers, with very spacious state-rooms specially ventilated, and with every improvement which experience has suggested as suitable for the intended trade, with marble baths, lavatories, &c. &c., and fitted throughout with electric light. The first-class dining-room is situated in a large house on deck, and will be panelled with marble and inlaid woods in the handsomest possible manner, the deck over the house being extended as a sunshade to the sides of the vessel so as to give shelter underneath it, and form a spacious promenade above for passengers under the protection of the awnings. A large cooling chamber is placed in the 'tween decks, fitted with Hall's refrigerating machinery, so that fresh provisions can be kept throughout the voyage. The dimensions of the vessel are:—Length, 343ft.; beam, 43ft.; depth moulded, 25ft. 6in. The machinery will be supplied by Messrs. Thomas Richardson and Sons, of Hartlepool, consisting of triple-expansion engines with cylinders 25in., 39in., and 67in. by 45in., with two large boilers working at 180 lb. pressure. On leaving the ways the steamer was named the Leopoldville by Miss Inga Raylton Dixon, daughter of the builder. Messrs. Dixon and Company have five other large steamers on the stocks in various stages of construction, besides two lying in the water waiting for engines, and the keel of a China tea steamer of about 6000 tons will at once be laid down on the berth vacated by the Leopoldville.

---

Railways in Japan.—The first railway in Japan was commenced in 1870, and there are now more than 1900 miles of railway working, besides several lines under construction or proposal, among which a few of the foremost are, according to the *American Engineer*, the Imperial Government Railway, 557·61 miles; Niphon Railway Company, 593·08 miles; Sanyo Railway Company, 145·10 miles; Kinshin Railway Company, 136·76 miles; Tanko Railway Company, 205·09 miles. The standard gauge of Japanese railways is 3ft. 6in. The permanent way consists of flat-bottomed steel rails weighing 60 lb. per yard, laid on cross sleepers, except 66½ miles for Tokyo-Yokohama and Kobe-Kyoto lines, on which double-headed rails on cast iron chairs are used. On the Kobe-Kyoto line cast iron pot sleepers were first tried, but they were gradually replaced with timber cross sleepers. Lately an experiment was made with earthenware sleepers in the Shinbashi Station compound. As there is an abundant supply of wood in Japan, and it is not attacked by insects, timber sleepers answer very well. The railway, are mostly single lines, with the following exceptions:—Shinbashi-Yokohama line, 18 miles double line; Numadzu-Oyama line, 22 miles; Ueno-Omiya line, 16¾ miles; total, 56¾ miles double line. As the country is mountainous and full of rivers and running streams, there are several engineering works—deep cuttings, high embankments, tunnels, bridges, and culverts. In order to carry out earthworks, temporary rails are used. The Japanese coolies are not at all accustomed to use wheelbarrows, but they are well trained to carry earth, stone, or anything on their shoulders with straw net or *mokkō*. In blasting rocks, gunpowder, dynamite, and other explosives are used.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

⁎ When patents have been "communicated" the name and address of the communicating party are printed in italics.

*6th September*, 1894.

16,975. Lawn Clippers, W. Burrows, London.
16,976. Heating Boiler Furnaces, &c., C. Naylor, London.
16,977. Machine for Stuffing Mattresses, R. R. Thompson, London.
16,978. Briquette Fuel, A. E. Tavernier and W. L. Malcolmson, London.
16,979. Tooth Brushes, L. Ehrlich, London.
16,980. Machine for Printing Oil-cloth, W. H. Schornberg, London.
16,981. Combined Couch and Washing Appliances, E. L. Still, London.
16,982. Hunting Knife or Bayonet, T. Prasse, London.
16,983. Securing Rails to Metallic Sleepers, J. Whitestone, London.
16,984. Combined Fan and Motor, F. Eisenbeis, London.
16,985. Block-sawing Machines, C. Temperley, London.
16,986. Apparatus for Diffusing Vapour, E. W. Frazar, London.
16,987. Red Tint Producing Apparatus, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany.*)

17,084. Detecting the Removal of Goods, F. A. Newey, Layerthorpe.
17,085. Stable Brushes, G. J. Hobbs, Birmingham.
17,086. Preparing Wheat, J. T. O'Callaghan, London.
17,087. Wooden Wheels for Vehicles, W. C. Coggan, Bradford.
17,088. Moulds for Advertisements, W. H. D'A. Cleminson, Ayrshire.
17,089. Coat Hooks, G. Hudson, Birmingham.
17.090. Cork Holder for Feeding Bottles, A. Smith, London.
17,091. Bearings for Vehicles, W. Landell, Glasgow.
17,092. Collapsible Boxes, H. and A. W. Stevenson, Manchester.
17,093. Cream Separating Machine, F. G. Jones and H. Brecknell, Bristol.
17,094. Mill for Grinding Glass, H. Brecknell, Bristol.
17,095. Brushes, J. G. Willis, Wallsend-on-Tyne.
17,096. Sticking Edges of Pottery, P. Shelley, Longton.
17,097. Enlarging Photographic Negatives, T. P. Bethell and J. W. Rhodes, Liverpool.
17,098. Tram-car Starters, R. Mackay, Glasgow.
17,099. Waist Belt, T. S. Lavis, Devon.
17,100. Advertising on Matches, G. M. Dudley, Dublin.
17,101. Shuttle Boxes of Looms, D. Anderson, Glasgow.
17,102. Swinging Pontoon Bridges, D. Cunningham, Glasgow.
17,103. Apparatus for Drying Cocoa, R. T. Love, Glasgow.
17,104. Construction of Cabinets, S. G. Browne, London.
17,105. Ball Bearings, T. Gerrard, Burnley.
17,106. Gear of Steam Whistles, E. H. Atkinson, Goole.
17,107. Trunk Locks, A. J. Bates, Wolverhampton.
17,108. Coat Hooks, H. Taylor and W. Holland, Birmingham.
17,109. Tires for Cycles, R. Gordon, St. Andrew's.
17,110. Determining the Location of a Distant Object, B. J. B. Mills.—(*W. C. Rafferty, United States.*)
17,111. Piston Packings, R. F. C. Tonge and J. Butterworth, Manchester.
17,112. Oxidising the Protosalts of Iron, N. McCulloch, Glasgow.
17,113. Making Red Oxide of Iron, N. McCulloch, Glasgow.
17,114. Tobacco Pipes, E. W. Gilbert, London.
17,115. Motive Power Apparatus, M. Bates and R. Evans, London.
17,116. Wheels for Road Vehicles, E. Dagnall, London.
17,117. Articles of Furniture, J. Wetter.—(*The firm of Jacob and J. Kohn, Austria.*)
17,118. Hairpins for Ladies' Dresses, A. Franklyn, Manchester.
17,119. Fastener for Window Sashes, J. Byfield, Birmingham.
17,120. Casks for Containing Butter, R. Mahoney, London.
17,121. Sheet-metal Articles, A. J. Boult.—(*E. Hofmann, Germany.*)
17,122. Bicycles, P. J. Deacon, London.
17,123. Winding Cops, A. J. Boult.—(*F. H. Bishop, United States.*)
17,124. Hooks and Eyes, H. Marles, London.
17,125. Albums for Photographic Prints, P. T. Johnson, London.
17,126. Improved Head Gear, J. E. Mathewson, London.
17,127. Main Taps, J. T. Garratt, London.
17,128. Taps or Cocks, J. T. Garratt, London.
17,129. Soldering Irons, P. Stotz and F. W. Schindler-Jenny, London.
17,130. Heating Liquids, P. Stotz and F. W. Schindler-Jenny, London.
17,131. Brooms, J. R. Gilbert, London.
17,132. Nut Lock Washer, W. B. McMaster and F. W. Weise, London.
17,133. Making Hydrazo Compounds, E. Straub, London.
17,134. Brick-making Machine, W. J. N. Tomlinson, London.
17.135. Water Meters, P. C. Duch, London.
17.136. Carving Forks, G. A. Keeler and J. E. Beal, London.
17,137. Collapsible Life-saving Buoys, J. Richardson, London.
17,138. Rubber Tires for Wheels, H. Brooks, London.
17,139. Overcoming Load Resistance, W. Lowrie, London.
17,140. Construction of Spring Clips, S. H. Crocker, London.
17,141. Horizon Glasses for Sextants, G. C. Lilley, London.
17,142. Gas Lamps, T. W. Cowan, London.
17,143. Treatment of Beer, &c., T. D. Lichtenstein, London.
17,144. Treatment of Beer, &c., T. D. Lichtenstein, London.
17,145. Making Lead Pigments, &c., W. B. Priest, London.
17,146. Pots for Boiling Milk, W. P. M. Gottheiner, London.
17,147. Sliding Sash Windows, E. J. Nowell, H. J. Carter, and J. Weymouth, London.
17,148. French Casements, E. J. Nowell, H. J. Carter, and J. Weymouth, London.
17,149. Sash Windows, E. J. Nowell, H. J. Carter, and J. Weymouth, London.
17,150. Apparatus for Bottling Beer, F. W. Jacob, London.
17,151. Metal Cans or Cases, J. A. Lloyd, jun., London.
17,152. Rolling Metal Beams, W. R. Lake.—(*L. D. York, United States.*)
17,153. Bobbin Holders, N. A. Easton, London.
17,154. Breech-loading Guns, A. Siret, London.
17,155. Steady Cycle, L. Wain, Kent.

*10th September*, 1894.

17,156. Turnstiles, &c., S. A. N. Deluce, Cheadle Hulme.
17,157. Leather Binding for Wearing Apparel, A. Garstin, London.
17.158. Opener for Bottles, H. Essam, Woolwich.
17,159. Weighing Machines, J. Hines, Glasgow.
17,160. Apparatus for Beating Liquids, T. Morton, Wishaw.
17,161. Chains for Cycles, T. Poirotte.—(*P. Lavigne, France.*)
17,162. Registering the Length of Yarn, D. Whiteley, Huddersfield.
17,163. Toboggan Skate, H. K. McAllum, Newcastle-on-Tyne.
17,164. Omnibuses, &c., J. Darling, A. R. Harvey, and R. C. Lyness, Glasgow.
17,165. Drilling and Screw-cutting Machines, A. Pickard, Harrogate.
17,166. Point Protector for Pencils, T. Banford, Birmingham.
17,167. Suspenders for Lamps, G. F. Sanders, Birmingham.
17,168. Boat Chocks, J. Muir, Liverpool.
17,169. Disengaging Gear for Ships' Boats, J. Muir, Liverpool.
17,170. Removing Sludge from Docks, H. S. Patterson, Manchester.
17,171. Fixing Brushes to Handles, P. Lucas, Portsmouth.
17,172. Apparatus for Dyeing Yarns, J. Pritchard and F. A. Blair, Glasgow.
17,173. Flower Pots, J. S. Hislop, Glasgow.
17,174. Funnels of Furnaces, L. G. Kok, Glasgow.
17,175. Distilling Sea Water, J. B. Hepburn and C. R. Honiball, Liverpool.
17,176. Chimney for Incandescent Gas, E. R. Kraner, Berlin.
17,177. Holding Bobbins, J. Gregson, Preston.
17,178. Grain Cleaner and Separator, J. P. West, London.
17,179. Supports for Garments, A. McLeod, Glasgow.
17,180. Electric Arc Lamps, R. H. Jahr, London.
17,181. Laying a Grain on Metal Plates, J. Addison, London.
17,182. Application of Gold Leaf to Lace, R. Scott and C. Birch, London.
17,183. Bevel-edge Letter-press Dies, A. Lerpiniere and F. Wallen, London.
17,184. Sealed-bolt Buckle, J. Greenwood, London.
17,185. Connecting Lines of Window-sashes, C. S. Steel, London.
17,186. Clearers for Ring Frames, J. Brooks, London.
17,187. Screw-socket Broom, L. Lewis, London.
17,188. Cooking Vessels, F. Long, London.
17,189. Slotting Machines, F. and C. Berry, London.
17,190. Webbing Weft-fork Blanks, J. Schofield and J. Crabtree, London.
17,191. Medicated Pillow or Cushion, N. B. Paul, London.
17.192. Purse Frames, S. Nathan, London.
17,193. Frame for Gas-light Shades, J. H. Sharp, Helensburgh.
17.194. Punkah Machine or Apparatus, W. G. Doyle, Bournemouth.
17,195. Matrices for Linotypes, O. Imray.—(*C. Sears, United States.*)
17,196. Transferring Articles across Water, D. M. B. H. Cochrane, London.
17,197. Jess for Training Homing Pigeons, M. Arnold, London.
17,198. Bolts, A. Gray, London.
17,199. Axles of Vehicles, J. Tagell, G. B. Edwards, and T. Darby, London.
17,200. Rail Joints, G. B. Ellis.—(*The "White" Patent Rail-joint Company, Australia.*)
17,201. Imitation Cording and Stitching, J. Dowling, London.
17.202. Mechanical Musical Instruments, J. E. Mucker, London.
17,203. Spinning and Twisting Frame, A. Gruschwitz, London.
17.204. Packing-case for Pictures, C. J. Palmie, London.
17,205. Treatment of Textile Materials, A. Dicktus, London.
17,206. Shorthand and other Manuscript Books, G. Hayes, London.
17.207. Closing Bottles, F. H. Lenders.—(*A. Denaeyer, Belgium.*)
17.208. Substitute for Stone, F. H. Lenders.—(*C. Bertin, Belgium.*)
17,209. Cultivators, J. Bamford, Birmingham.
17,210. Packing-case for Cheese, N. McKeever and H. Gray, London.
17,211. Cutting Off Rivet Heads, W. J. Feckett, London.
17,212. Evaporating Vessels, T. Glover and J. Brock, London.
17,213. Attaching Studs to Garments, G. H. S. Farrant, London.
17,214. Elastic Tires for Velocipedes, B. J. B. Mills.—(*P. B. Carante and J. Bocuze, France.*)
17,215. Plucking and Collecting Fruits, L. Götz, London.
17,216. Producing Printed Maps, G. W. Bacon and T. Best, London.
17,217. Apparatus for Mixing Materials, J. E. Smith, Liverpool.
17,218. Goloshes, R. M. Crabbe, Liverpool.
17,219. Feeding Liquid Fuel to Furnaces, R. Altschul, Liverpool.
17,220. Embroidery Machines, H. C. Sheldon and W. Lockwood, London.
17,221. Fireproof Ceilings, J. Rueben, London.
17,222. Carriage Brakes, R. Tucker and F. Boyling, Edinburgh.

*11th September*, 1894.

17,223. Photographic Cameras, &c., J. Ashford, Birmingham.
17,224. Burglar Alarm and Bell, H. Bagley, Birmingham.
17,225. Hydraulic and other Presses, W. Blackwell, Stockport.
17,226. Coating Tin and Terne Plates, A. J. Maskrey, Bristol.
17,227. Needles, F. Merryweather, London.
17,228. Adjusting Tied Bows, C. E. Cotton, Portsmouth.
17,229. Fixing Ends to Poles, H. Windibank and T. E. Smith, Southsea.
17,230. Toy, F. G. Barham, Coventry.
17,231. Cricket and other Balls, C. J. Allen, Birmingham.
17,232. Wood Block Pavements and Paving, F. Hayes, Manchester.
17,233. Oil or Hydrocarbon Engines, J. H. Knight, Farnham.
17,234. Candlestick, J. and H. Smith, Sheffield.
17,235. Electric Incandescent Lamps, G. L. Philips, Holland.
17,236. Pipe Grips, J. T. Towlson, Great Yarmouth.
17,237. Combination Tool or Pincers, G. H. Coleby, London.
17,238. Stopping Noise of Inrushing Water, J. Spear, Portsmouth.
17,239. Oil, Vapour, and Steam Generators, G. Rose, Glasgow.
17,240. Gathered or Plaited Garments, R. Potter, Manchester.
17,241. Method of Copying Letters, W. W. McLauchlan, Manchester.
17.242. Sheet Separating and Printing, C. Reising, Manchester.
17,243. Method of Glazing Houses, J. Quertier, Bournemouth.
17,244. Road Sweeper, A. G. Brookes.—(*F. Hopewell, United States.*)
17,245. Index Cases, A. G. Brookes.—(*H. E. Davidson, United States.*)
17,246. Cock, W. R. Deacon, Bristol.

17,247. The Lytenklean, J. W. Lovell, Rushden, R.S.O.
17,248. Devices for Training Horses, L. Defoy, Manchester.
17,249. Latch and Bolt, E. Baller and E. R. Baller, Southport.
17,250. Neckties, Scarves, and Collars, E. R. Baller, Southport.
17,251. Arresting Decay in Raw Meat, J. A. Wilson, Dundee.
17.252. Perforating Machine, P. W. Peckham, Glasgow.
17,253. Recording Volume of Liquids, W. P. Bruce, Glasgow.
17,254. Utilisation of Waste Products, R. Pickup, Manchester.
17,255. Lid or Cover for Boilers, &c , J. McCullagh, Dublin.
17,256. Pipes, W. Freeman, Leicester.
17,257. Compress or Poultice Protector, I. M. Hemsteger, London.
17,258. Toy Rowing Boat, B. Gott and E. Cousens, London.
17,259. Boiler Tubes, A. J. Boult.—(*C. W. Whitney, United States* )
17,260. Gearing for Bicycles, V. D. Cruser, London.
17,261. Friction Clutch, W. Spiess and C. H. Stoldt, Hamburg.
17,262. Fire Extinguisher, A. Köhler and C. H. T. Stoldt, Hamburg.
17,263. Scarfing the Edges of Metal Plates, H. Smith, H. Smith, jun., and O. Smith, Glasgow.
17,264. Photographic Changing Box, S. J. Levi and A. J. Jones, London.
17.265. Applying Hair to Artificial Skins, F. C. Tussaud, London.
17,266. Lock-up Date and Time Stamp, B. Warwick, London.
17.267. Shafts of Children's Mail Carts, G. Lacey, Dewsbury.
17,268. Convertible Tricycle, F. Leclercq. London.
17.269. The Safety-pin Spring Cuff, F. Jones, London
17,270. Domestic Cinder Sifter, B. Plummer, Newcastle-on-Tyne.
17,271. Propeller Pencils, B. Willcox.—(*The Eagle Pencil Company, United States* )
17,272. Looms for Weaving, E. Jansen, London
17,273. Rotary Motors, W. R. Lake—(*The Consolidated Car Heating Company, United States.*)
17,274. Apparatus for Drying Salt, &c , T. Craney, London.
17,275. Salt Evaporators, T. Craney, London.
17,276. Hinges, J. B. Knittel, London.
17,277. Alcoholic Ferment Mash, J. Takamine, London.
17,278. Mechanical Telegraphs, T. Tomlinson, London.
17,279. Cooking Kettles, B. C. Sabin, London.
17,280. Attaching Broomheads to Handles, F. W. Whitlock, London.
17,281. Transformer for Electric Currents, W. J. Still, London.
17,282. Kilns for Burning Bricks, &c., J. Hamblet, London.
17,283. Bicycles, &c , J. V. Pugh, London.
17,284. Distribution of Electric Currents, J. F. McElroy, London.
17,285. Steam Generators, C. D. Mosher, London.
17,286. Steam Generators, C. D. Mosher, London.
17,287. Valves for Engines, P. A. Newton—(*The Ingersoll-Sergeant Drill Company, United States.*)
17,288. Condiment-holding Appliance, A. E. Crawford, London.
17,289. Condensation of Nitric Acid, H. E. Newton.—(*E. Hart, United States.*)
17,290. Umbrella Tip-cup, F. W. C. Carr, London.
17,291. Manifolding Autographic Registers, W. Assheton, D. Stewart, and C. J. Carroll, London.
17,292 Pessary, J. A. Hurdle, London.
17.293. Dumping Apparatus, W. McMahon and H. J. Reilly, London.
17,294. Bearings for Rotary Blowers, W. W. Wainwright, London.
17.295. Check Book Covers, &c., N. J. H. Kenney, London.
17,296. Armatures for Dynamo-electric Machines, W. R. Lake.—(*R. Eickemeyer, United States.*)
17,297. Armatures for Dynamo-electric Machines, W. R. Lake.—(*R. Eickemeyer, United States.*)
17.298. Novel Construction of Bottles, A J. Weir, London.
17,299. Fire-escapes, E. Kallenberg, London.
17.300. Boot and Shoe Last, W. Armes and O. Wendt, London.
17,301. Braking Device for Cranes, &c., H. Schlösser, London.
17,302. Car Fenders, R Haddan.—(*The Darrach Car Fender Company, United States.*)
17,303. Pneumatic Tire Inflating Apparatus, R. Lucas, London.
17,304 Pneumatic Tires, W. S. Williams, London.
17,305. Printing Machinery, A. F. Battey, London.
17,306. Paper-making Machinery, T. A. and C. D. Marshall, London.
17,307. Cartridges, E. Rubin, London.
17,308. Internal Combustion Engines, J. Roots, Teddington.
17,309. Pasteurising Apparatus, C. W. Ramstedt, London.
17,310. Razor Guards, F. Lomas and T. Crookes, London.
17,311. Protection against Projectiles, A. Appelt, London.
17,312. Casters, L. B. Denton, London.
17,313. Electric Motors, J. S. Losch, J. H. Phillips, J. W. Moyer, and J. H. Williams, London.
17,314. Treating Powdered Materials, J. S. Detwiler, London.
17,315. Blending Powdered Materials, J. S. Detwiler, London.
17,316. Attachment for Umbrellas, &c., S. Joseph, London.
17,317. Pipe Couplings, J. J. Hanbury, London.
17,318. Pipe-making Machinery, R. Stanley and G. Beck, London.

*12th September*, 1894.

17,319. Combined Time-piece and Compass, R. Rood, Southampton.
17.320. Rim Lock Furniture, P. Fugler, Tunbridge Wells.
17,321. Rule, F. R. Jones and L. W. Jones, Birmingham.
17,322. Funnel, W. G. Behenna, St. Austell, Cornwall.
17,323. Combination Kitchen Dresser, T. Dobson, Lancaster.
17,324. Waterproof Paper Bag, W. C. Haigh, Manchester.
17,325. Bottling Aerated Liquids, H. W. Payne and H. C. Cox, Birmingham.
17,326. Egg and Globe Shooting Apparatus, J. Wright, Staffordshire.
17,327. Buttonholes, S. Keightley, London.
17,328 Rope-making Machinery, F. Raichl, London.
17,329. Boots, F. T. Walsh, London.
17.330. Plugs, &c., for Lavatory Basins, K. Jenkins, London.
17.331. Heel Protectors, T. C. Whitney and H. L. G. Dane, London.
17,332. Springs for Cycle Saddles, J. C. Lees, London.
17,333. Envelopes, W. J. Tate, London.
17,334. Apparatus for Pasting Paper, G. Newsum, Bradford.
17,335. Electrically Governing the Voltage of Dynamos, J. Graham and H. Chapman, Bradford.
17,336. Hot-water Boilers, H. Leggott, Bradford.
17,337. Velocipede Saddles, E. Woods, Liverpool.
17.338. Shuttles for Weaving Looms, J. Waddington, Bradford.
17,339. Combined Portiere Rod, &c., J. Hall-Edwards, Birmingham.
17,340. Treatment of Molten Iron, &c., G. Love, Durham.
17,341. Joining Shackle, F. J. and M. B. G. Sinnette, Southampton.
17,342. Scissors, M. M. Smith, Manchester.
17,343. Automatic Atmospheric Ink-supplying Bottle, A. H. Lessells, Cheshire.
17,344. Blind Roller and Slip, W. H. Jordan, Worthing.
17,345. Golf Club, J. D. Dickson, Glasgow.
17,346. Draughtsmen's Squares, S. W. Wilkinson and R. F. Drury, Sheffield.
17,347. Differential Screw Connector, C. P. Kinnell, London.
17,348. Rain and Pocket Protecting Seat Cover for Omnibuses, C. Morgan, London.
17,349. Picture Hook, H. Munslow, London.
17,350. Flange headed Nails, H. Munslow, London.
17 351. Fog-signalling Apparatus, W. A. and G. A Stephens, London.
17.352. Construction of Screw Propellers, C. Givone, London.
17,353. Charging Batteries, S. Miller and C. J. Grist, London.
17.354. Exhibiting Handkerchiefs, &c., J. Bromilow, London.
17,355. Watch and Eyeglass Pocket, J. S. Templar, London.
17.356. Washing, &c., Potatoes, J. Shackleton, London.
17,357. Electric Lamps, S. S. Allin and W. H. Wood, London.
17,358 Stand for Photographs, &c , E. Drechsler, London.
17,359. Driving Mechanisms for Velocipedes, C Stotesbury and W. M. White, London.
17,360. Indicator for Steering, E. A. Veale and W. R. Hayes, London.
17,361. Ladies' Boa Fastener, F. H. Whitlock, London.
17.362. Effecting Photographic Exposures, C. D. Durnford, London.
17,363. Cornice Pole Brackets, R. Jones, London.
17,364. Apparatus for Lace Machines, H. Tiddiman, London.
17,365. Raising Electric Standards, R. W. Braham, London.
17.366. Tiles, Craven, Dunnill, and Co., Ld., and T. Pitt, London.
17,367. Neck-ware, W. Willeringhaus, London.
17,368. Manufacture of Pocket-knives, A. J. Beal, London.
17,369. Secondary Voltaic Batteries, L. Epstein, London.
17,370. Separating Burrs from Wool, G. Riche and A. Rivret, London.
17,371. Horseshoes, W. H. Walker, London.
17,372. Purifying and Sterilising Water, W. Lawrence, London.
17,373. Steam Traps, V. C. J. Ortmans, London.
17,374. Filters, G. Fouchard, London.
17,375. Spring Tire, P. J. Vetter, London.
17,376. Umbrellas, K. Hyman, London.
17,377 Friction Gear, G. G. M. Hardingham.—(*C. Raleigh, South Africa* )
17,378. Transformers, A. B. Blackburn and T. L Boyden, London.
17,379. Electrical Cranes, B. Willcox.—(*The Eisenwerk vormals Nagel and Kaemp Actien Gesellschaft, Germany.*)
17,380. Stoppering Bottles, W. R. Lake.—(*A. A. Pindstofte, Denmark.*)
17,381. Boot-trees, F. E. V. Taylor, London.
17,382. Flow-pipes, W. Youlten, London.
17,383. Bearings, C. W. Brown and M. D. Rucker, London.
17,384. Burglar Alarms, T. A. Clarke, Liverpool.
17.385. Automatic Delivery Machines, T. Cain, Liverpool.
17,386. Station Indicators, M. Treitel and G. Tresenreuter, London.
17,387. Bottles, J. Bradley.—(*The Phœnix Company, New Zealand.*)
17,388. Kettles, Saucepans, &c , C. H. Hutton, London.
17,389. Tap and Measuring Device, E. Clairmonte, London.
17,390. Letter Paper and Envelopes, J. Pitt, London.
17,391. Mud-guards for Bicycles, W. Bransom, London.
17,392. Utilising the Energy of Running Water, R. D. Verbeek, London.
17,393. Transmission of Coins by Post, E. W. Kneen, London.
17 394. Motor and Drilling Machine, J. Abbott, London.

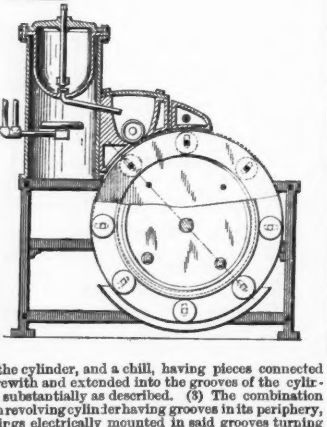
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**521,791.** Machine for Making Storage Battery Grids of Forced Lead, *W. W. Griscom, Haverford, Pa.—Filed July 24th*, 1893.

*Claim.*—(1) A mould comprising a revoluble cylinder having recesses extending around its periphery and provided with excentric ejectors, rotating with the mould, substantially as described. (2) The combination with a revolving cylinder having annular grooves in its periphery, of rings excentrically mounted in said grooves, turning with the cylinder on an axis excentric thereto, a reservoir arranged to supply metal for the cylinder, and a chill, having pieces connected therewith and extended into the grooves of the cylinder, substantially as described. (3) The combination with revolving cylinder having grooves in its periphery, of rings electrically mounted in said grooves turning with the cylinder on an axis excentric thereto a reservoir to contain the metal, and means for forcing the metal into the cylinder, substantially as described.

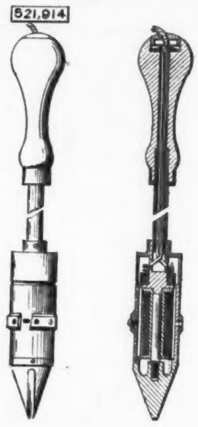
521,791



**521,914.** Electric Soldering Tool, *J. F. McLaughlin, Philadelphia, Pa.—Filed May 19th*, 1893.

*Claim.*—(1) In an electric soldering iron, the combination of a casting, a spool or bobbin removably mounted upon the same, a heating coil upon the spool and binding posts to which the terminals of the coil are detachably secured, with leading wires also detachably secured to the binding posts, a metallic mantle for the coil, and a removable bit securing the mantle in place, substantially as described. (2) In an electric soldering tool, the combination of a heating coil and an inclosing mantle provided with a circumferential series of heat radiating passages, with a ring, rotatable upon the mantle provided with holes corresponding to the said passages, whereby the latter may be partly or wholly closed and the heat of the tool regulated, substantially as described.

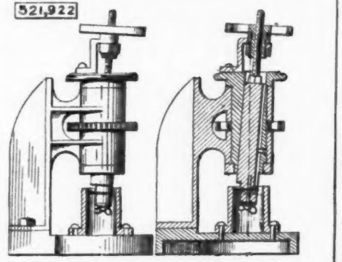
521,914



**521,922.** Metal Boring Machine, *D. Stevenson, Cold Spring, N.Y.—Filed January 30th*, 1894.

*Claim.*—(1) In a boring machine, the combination with suitable bearings, of a rotating bar spindle mounted for a fixed rotation in said bearings and having a longitudinal oblique bore crossing the central longitudinal axis thereof, a boring bar mounted for a longitudinal movement in the oblique bore of said spindle and adapted to turn therewith, means for adjusting the boring bar longitudinally in the spindle and for feeding the same beyond the spindle and into the work, and a tool axially adjustable on the lower projected end of said boring bar, substantially as set forth. (2) In a boring machine, the combination with the bed-plate or table for the work, of the bearing upright having an off-standing vertically-disposed cylindrical bearing, a spindle removably mounted for a fixed rotation in said bearing and having an upper flanged end, an exteriorly-threaded lower end projecting below the cylindrical bearing, and an oblique opening extending longitudinally therethrough, a gear wheel attached to said spindle at a convenient point intermediate of its end, a screw ring removably engaging the lower exteriorly-threaded end of the spindle, and fitting against the lower end of the cylindrical bearing, a boring bar mounted for longitudinal movement in the opening of the spindle and carrying a tool at its lower projected end, beyond the spindle, and a feeding screw connected to the upper end of the boring bar and geared with suitable operating means, substantially as set forth.

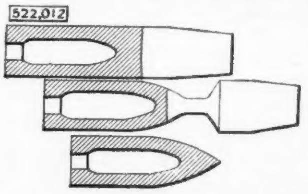
521,922



**522,012.** Shell, *R. A. Hadfield, Sheffield, England.—Filed May 28th*, 1892.

*Claim.*—(1) The herein-described projectile, it having its rear end left in the condition of a casting, and having an integral forged nose or point, substantially as and for the purposes described. (2) A projectile having its chambered rear end left in the condition of a casting, and having an integral forged nose or point, substantially as and for the purposes described.

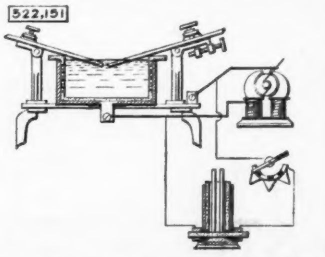
522,012



**522,151.** Method of Heating Metals Electrically, *C. L. Coffin, Detroit, Mich.—Filed November 16th*, 1893.

*Claim.*—(1) The herein-described method of electrically heating metal, consisting in heating the metal, connecting it with one terminal of a generator of electricity, bringing it in contact with a liquid electrode connected with the other terminal of said generator, and establishing a voltaic arc between the two electrodes. (2) The herein-described method of electrically heating metal, consisting in heating said metal previous to its immersion in a liquid electrode, connected to one terminal of a source of electric energy, the said metal being connected to the other terminal of the source of electric energy, and establishing a voltaic arc between the electrodes. (3) The herein-described mode of heating metal electrically, consisting in dipping a heated piece of metal into a liquid, passing an electric current through said metal and liquid, and establishing a voltaic arc between the electrodes.

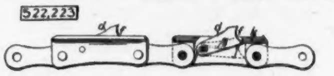
522,151



**522,223.** Carrier Chain for Feeding Boards to Wood-working Machines, *B. G. Luther, Worcester, Mass.—Filed June 15th*, 1893.

*Claim.*—In a carrier chain, the combination with the carrier link provided with the shoulder *k*, of the pivoted engaging dog *d*, provided with the recess *j*, and with the lip *j* adapted to engage with the shoulder *k*, and the spring *g*, arranged substantially as described.

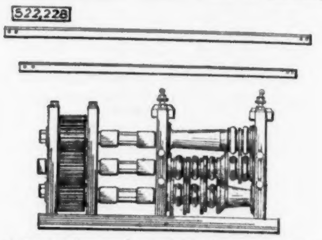
522,223



**522,228.** Process of Renewing Old Steel Rails, *E. W. McKenna, Milwaukee, Wis.—Filed July 26th*, 1892.

*Claim.*—The process of adapting old steel rails to further use, which consists in heating the same to a temperature near to, but below, the point at which the carbon contained therein would be materially affected, simultaneously straightening and reducing the cross section thereof equably in all its parts, but keeping the rail of the original height, and then sawing off the ends, whereby a rail of reduced cross section, but of the same or greater length and the same height as the original rail is produced.

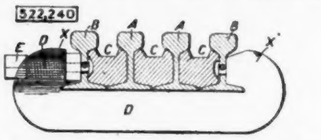
522,228



**522,240.** Railway Frog, *A. L. Stanford, Evanston, Ill.—Filed January 11th*, 1894.

*Claim.*—In a railway frog, the combination of the wing rails B and the point rails A braced intermediately by filling C or the like, of clamps D and D$^1$, each comprising a bar having its ends turned toward each other, affording the hook-shaped extremities X and X$^1$, the said clamps embracing the frog across its base so as to confine the wing and the point rails thereof, said hook-shaped extremity X$^1$ being provided with the projection *d* to penetrate the web of the wing rail to prevent the clamp from slipping from place, and tightening bolts E and E$^1$ for tightening said clamps, substantially as described.

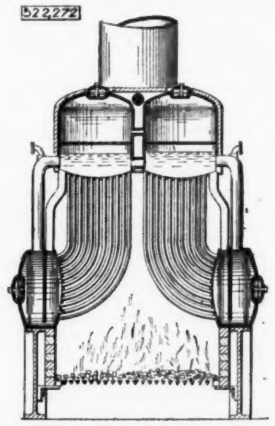
522,240



**522,272.** Water-tube Boiler, *M. H. Plunkett, Baltimore, Md.—Filed September 23rd*, 1893.

*Claim.*—(1) In a steam generator, in combination a cylindrical chamber arranged horizontally, along the side of a furnace, a cylindrical steam chamber arranged vertically above the furnace, bent or curved pipes passing through the furnace and connecting the inner end of the water chamber with the bottom end of the steam chamber, and return tubes located outside the furnace and connecting the steam and water chambers, substantially as set forth. (2) In a steam generator, in combination, horizontally placed cylindrical water chambers arranged in two series in lines with their diameters forming the sides of the fire-box, vertically placed cylindrical steam chambers arranged in two similar rows placed above the water chambers and forming the top of the fire-box, an open space being left between the rows of steam and water chambers for furnace room, and curved pipes connecting the inner ends of the several steam and water chambers, and return tubes located outside the fire-box and connecting the steam and water chambers, as and for the purpose set forth.

522,272



**522,273.** Valve Mechanism for Blowing Engines, *E. Reynolds, Milwaukee, Wis.—Filed May 1st*, 1893.

*Claim.*—(1) A hollow rotatable valve, having closed ends, and also a series of equally-spaced longitudinal bars *b* to form immediate ports in combination with a valve chamber having inlet and outlet ports, and means for rotating the valve in but one direction. (2) In a blowing engine or air compressor, a cylindrical hollow valve having longitudinal bars separated from each other to form ports, and closed at its ends, means for rotating the valve in one direction, and a valve chamber provided with an inlet port to permit access of the air into the valve at all times, and provided also with an outlet ports or ports.

## COLONIAL LOCOMOTIVES.

The question whether English or American locomotives are best adapted to colonial railways is one which has received a considerable amount of attention for many years past from engineers abroad. It is somewhat unfortunate for the Governments and corporations owning the railways that this attention has usually been bestowed after the engines have been landed and paid for, thus in many instances leaving a large equipment most unsuitable to the conditions under which it has to work.

Taking in review the rolling stock of the Australian Colonies, it is surprising to find the number of experimental types of engines which have been apparently ordered at random, in small batches, from various makers, English, American, and Colonial—legacies, in many cases, from locomotive superintendents of limited experience who have been changed, at short intervals, often for political reasons. It may be interesting to note the various results which have been obtained after these years of experimenting.

In Western Australia, where the railways are still in an embryo state, and have been largely built with English capital, the English engine at present is universal. It is quite probable, however, that this Colony will go through the usual throes of experimenting as it developes its resources.

In South Australia, where the railways have been constructed to two gauges—3ft. 6in. and 5ft. 3in.—engines of the English type will be found as the standard for the broad-gauge lines, while the American type, with colonial modifications and locally built, has been adopted for the narrow gauge, both for goods and passenger. Possessing two gauges, South Australia loses somewhat for purposes of comparison with other Colonies as to the best adapted locomotive for its railways, from the fact that a broad-gauge line is seldom constructed unless there is sufficient traffic to warrant its being maintained in a reasonable condition of repair, the narrow-gauge lines being left to grapple with the outlying districts of small traffic receipts and lightly constructed, poorly maintained permanent way.

The Colony of Victoria, which has for many years built all its own locomotives, and has a gauge of 5ft. 3in., has adhered almost entirely to the English type of engine. As these engines run through a fairly level country, which is for a new Colony exceedingly well populated, and have not any very long stretches of outlying road, it has never been compulsory to make any radical departures from the practices of the old country.

New South Wales—of which more will be said hereafter—has an almost indefinite number of types of locomotives, many of which are being allowed to fall out of existence as the engines wear out. It is a subject of doubt at the present moment which types will eventually be adopted as standard, though they are almost certain to be of the English family, unless there is some unlooked for change in the administration of the Colony. Amongst the number of useful engines are some four varieties of American construction, in addition to some two others which are being allowed to fall into disuse. With a total of about 2600 miles of road open for traffic, much of which is through mountainous country, with gradients in many places of 1 in 40, the main trunk lines of good construction, and the branch lines or feeders, though well laid and fairly maintained, of a somewhat lighter description, it will readily be seen that New South Wales possesses unusual advantages as an arena for a contest between the rival locomotives.

Passing on to Queensland, a younger, though larger, Colony, with a mileage almost equal to that of New South Wales, though built at a considerably less cost, being all 3ft. 6in. gauge, it will be found that after years of experimenting with almost every conceivable type of engine, from the Fairlie double-ended design to a diminutive copy of the English standard goods, that the American type with colonial modifications and locally built has been adopted both for passenger and goods traffic. Beyond the fact that these engines are somewhat heavy in their consumption of coal, the choice seems to to have been warranted by the successful results.

Were it possible to have access to the engineers' account books of the various Colonies, it would be an easy matter to decide the question of the most suitable locomotive; but this not being feasible, only the information to be gathered from public records and statements, together with any personal knowledge, is for the time available.

It has been much debated amongst railway engineers whether the introduction of heavier engines would result in a reduction of working expenses. The following extract from the report of the Chief Mechanical Engineer of the New South Wales Railways to the Commissioners, and which is embodied in their annual statements for 1893, should go far to prove that such is the case:—"A very large reduction took place in the mileage during the year, which was largely due to the extended employment of more powerful engines, but by economies in the expenditure, a saving of nearly 1¼d. per train mile has resulted, when compared with the result of last year. The whole of the new American engines have been at work throughout the year hauling loads of live stock and goods in single trains; for such loads two engines had been employed previous to their introduction, and consequently their influence in the reduction of train and unprofitable mileage has been substantially felt."

In 1892 the train mileage was 8,356,096, and the engine mileage 12,362,105. In 1893 the train mileage was 7,505,310, and the engine mileage 10,154,648, which shows a decrease of 850,786 train miles and 2,207,457 engine miles, an actual reduction of 948,705 unproductive engine miles, supposing the ratio of train miles to engine miles of 1892 to have been maintained. This should prove, having reduced the cost of working—from the same report—from 22·783d. per train mile in 1892 to 21·632d. in 1893, that the introduction of powerful engines in a country where the grades are heavy is attended with results of a most satisfactory character. Beyond doubt, equally good results will be obtained in all sparsely-populated districts where the traffic is small and of an intermittent nature, as is all agricultural and pastoral produce. Thus, a frequent service of trains not being warranted, it will consequently be found that great economy will result from being able to haul all the traffic on one trip with a heavy train, in preference to making two trips with lighter engines.

The recent depression in trade in Australia has clearly demonstrated that more capital has been sunk in constructing the railways than the traffic receipts promise to pay adequate interest upon. It will therefore be considered necessary in the future to use a still lighter and cheaper form of construction, not to cost more than £2250 per mile.

In order, therefore, to comply with both the above conditions, it will be readily seen that an engine which will draw a heavy load over a lightly and cheaply-constructed road-bed will be one of the chief requirements of the colonial future. This can only be effected in one way, viz., by the careful and even distribution of as great a weight as can be carried with safety by the road-bed, and will vary according to the section of rail and nature of ballast, over as long a wheel base as can reasonably be obtained. It is here that the American locomotive engines have made their prime success. By increasing the number of coupled wheels, and evenly distributing the weight over them, they have complied with the chief requirements of a light railway. In order to compare the difference in some of the main features of English and American engines, the principal dimensions and weights of a few of the leading classes used in the Argentine Republic are shown in detail below. They are taken from the report of the Government experts who in 1892 were instructed by the Department of Engineers to the Republic to examine the rolling-stock equipment of the Southern Railway. The engines picked out are taken as being nearest to each other in size. A few extracts from the report may be of interest.

*Comparison of English and American Locomotives.*

| Service | | Pass. | Pass. | Goods. | Goods. | Goods compound. |
|---|---|---|---|---|---|---|

| Cost of repairs for two years | £ | 360 | 100 | 390 | 100 | 390 |

"As regards quality of material and its strength, it is all that could be desired; but the builders did not take into account the character of the road-bed on which it was to run, and therefore made it too heavy and the wheel base too rigid. The locomotives might run well enough upon European roads, which are substantially built and well ballasted; but such is not the case in this province, where most of the railways are built on loose soil. The result is a large increase in the cost of maintenance of way and repairs to rolling stock." And in conclusion, after a careful and exhaustive inquiry, these gentlemen remark: "It may be concluded, from all the data furnished in this report, that the Southern Railway locomotives are but iron masses, entirely injurious to the roads and interest of the company, and that a large part of its rolling stock is unnecessary for the service of its lines, as neither the condition of its roads nor the necessities of its traffic require it."

The whole of the equipment was supplied from England by first-class makers; and though no doubt the Argentine engineers are somewhat harsh in their judgment, from the fact that a number of compound engines are found in the list together with a class of engines known as "single-wheelers" which are used in England for light express traffic, it must be concluded that the authorities responsible for ordering the rolling stock are more to blame than the makers, from their ignorance of the actual requirements of the country.

Comparing the English equipment of the Southern road with the American outfit of its Western neighbour, the following remarks in the report may be noted:—"The construction of the sixty locomotives, notwithstanding their simplicity, is first-class, except in a few details, which by no means affect their good conditions for service. The thirty locomotives for mixed trains have withstood very severe tests during the period when the railways had not the number necessary for its service, as, notwithstanding the excessive amount of work imposed upon them, the results have been very satisfactory and economical." It would certainly appear that these gentlemen held a brief for the Americans, and from the cost stated for repairs, as compared with the English-built locomotives, it is apparent that, either there is a very peculiar system of keeping accounts, or that figures have been somehow manipulated. An annual cost of £180 for maintaining a comparatively new engine in repair, even making due allowances for the increased rates ruling abroad, would be a high figure, while the sum of £50 attributed to the American engine must be equally, or more so, erring in the other direction. Should these figures, however, be correct, it is a matter of regret that American engines have not been adopted in England many years ago, as the average cost in that country of maintaining engines in repair is from £70 to £100 per annum. Regarding the stated consumption of coal, it is admitted that the dead loads hauled on the Western road are only about one-third of those on the Southern, the coaches and trucks being of American construction, and consequently of considerably lighter build. When the Railway Commissioners of New South Wales in 1891 decided to place upon their lines a more powerful description of locomotive than had hitherto been used, they submitted a specification to makers in England and America, stating the load to be hauled, the gradients, and the speed required; full particulars of which, together with the dimensions and weight of the two classes of engines supplied, will be found in a later issue. It may be stated here, however, that they were six-wheeled coupled, with cylinders 21in. by 26in., fitted with four-wheeled bogies, and of a weight corresponding with these enormous cylinders.

The American engines being first to arrive were, after the usual preliminary mileage with goods trains, placed upon passenger traffic, with the result that in a short space of time three of the bogie axles broke off short at the journal, which necessitated the withdrawal of the whole from service pending investigation. A commission of experts was afterwards appointed to inquire into the qualifications of these engines for passenger traffic; and after a protracted sitting and the hearing of much evidence, it was decided that they were unsuited for that purpose, and it was recommended that they should be retained for fast goods and stock trains. As will be seen from the list of weights and dimensions when published, the weight of these engines is excessive, and as those imported from England, though much lighter, performed their work in a manner which could not be excelled, it must be considered that the immense weight was unnecessary, and therefore a fault of design. It was chiefly on account of the weight, coupled with the fact that the material and workmanship were of a character incompatible with the care of human life expected in English countries from the travelling public, that the commission decided as they did.

The praiseworthy manner in which the English locomotives performed their work requires no further comment; and it may be stated, without much fear of contradiction, that the cost of repairs has been found at least 30 per cent. less than that of the American type. Also, could adequate conditions of test be applied, that the consumption of coal would be less to an appreciable degree. During the time that the American engines were running the mail service, it was found necessary to employ two firemen to each engine—not only on account of the heavy firing required, but because the arrangement of cab and footplate was such as rendered the fireman useless to assist the driver in keeping a lookout, and in the numerous other minor duties usually performed by him.

There are many points about American engines which require to be carefully considered before arranging to put them to work upon railways which have been constructed by English engineers upon their usual principles; and by so doing many of the sources of expense met with in New South Wales will be avoided. In ordering heavy engines, it should be clear that the rails are of such section as will bear their weight with safety, and that sufficient margin has been allowed in the construction of bridges for the additional strain that will be put upon them. Also it will be found that the position of the cylinders, and their great width over all, will cause fouling of the brickwork at stations, unless the platforms are set unusually far back, thus leaving a considerable space between them and the side steps of the carriages, forming a source of great danger to passengers both entering and leaving their compartments, by night especially. It must be remembered that in America raised platforms are not general, their coaches not requiring it, and that the space between roads or six-foot is much greater than in England. Engines with cabs and overhanging gear designed to pass one another in a space of 8ft., when brought within 6ft. are apt to be found most unpleasantly close together. It has been found in some cases that only about 8in. clear space remains between two engines standing on different roads; and, having regard for the manner in which American engines roll about on their springs, this is not enough to fulfil the usual conditions of safety. Again, in large engines the Americans hoist their boilers to such a height that to clear bridges, &c., built to the English standard limit, the chimneys have to be shortened to such an extent as to give a most unsightly appearance, even if not interfering with the proper working of the draught. Cow-catchers are a source of danger to shunters coupling trucks, and carriages built with the usual double buffers and central coupling, from the distance they project, being liable to mutilate the man's legs when standing in the four-foot. An American whistle, except where an absolute necessity for clearing the road of cattle, should never be introduced, as the shock to nervous passengers and children travelling, especially at night, is positive cruelty, in addition to being a source of nuisance to the population living around stations, crossings, and other places where it becomes requisite to sound the whistle. The quality of the coal to be burned should also be clearly set forth, as the enormous length of fire-box found on American engines and their contracted exhaust nozzles, which tear up the fire and vomit sparks, clinkers, and ashes to the detriment of the fireman and the surrounding country, remind us of the days when their fuel was firstly wood and then anthracite coal, which latter requires a draught, quite unnecessary where good steam coal is procurable. In comparing the cost of American engines with those of English manufacture, it must not be overlooked that, unless stipulated to the contrary, the Americans do not provide for copper fire-boxes and brass tubes, which in the Colonies, where repairs are cheaper than renewals, and the water being seldom filtered or in any way treated, cannot be classified as good, are looked upon as a good investment.

New South Wales certainly deserves credit for having, not only on the present occasion endeavoured to find an engine really suitable for its railways, but for having also made two former attempts, first to Anglicise the American engine by having drawings made from one imported from that country with such modifications as suggested themselves at the time — which modifications it is to be regretted were not all they might have been—and then having the engines built in England. The success of this venture would probably have warranted its repetition had the same superintendent remained in office. The second attempt was to Americanise the English locomotive, and resulted in failure, and as the improvements (?) consisted chiefly in extending the smoke-box, reducing the size of the driving wheels, and placing the cylinders outside the frame—when they might just as well have remained in—without adding in any way to the hauling power of the engine, being only four wheels coupled, it is not a matter of great surprise. Had these engines been made six-wheel coupled, with an adequate boiler, the purpose for which they were intended would probably have been attained. A careful study of American engines, with a few years of experience in their actual working, will soon convince the most sceptical that the principles upon which they are constructed render them admirably adapted to the conditions which the colonial railways demand, and that they have many points which are immeasurably superior to the English article. We may name the flexibility of their springs—to which the Americans devote a vast deal of attention—which are hung on compensating levers, allow the weight to adjust itself easily to the road, thus saving shocks to both the engine and the permanent way. Their flexible bogies, and their apparent immunity from derailment under ordinary conditions. The power saved in running round curves of small radii, so common in hilly countries with railways of cheap construction, by dispensing with the flanges on the middle driving wheels, enabling them to be most suitably and evenly spaced, and rendering any number of coupled wheels possible. The equal distribution of the weight over all axles so dear to the Americans and so beneficial to the road. The enormous capacity of the tenders for both coal and water, an arrangement which is economical and praiseworthy to a degree, in places where the water supply is untrustworthy, and where it is not unusual in the event of the failure through drought of a watering station to have to go on thirty or forty miles to the next, often with small tenders requiring part of the load to be shunted in order to get through, or often entailing total failure. The economy and advantage of being able to carry coal sufficient for the round trip when making a journey to the interior on a branch line, possibly through mountainous country, thus saving hauling, at enormous cost, trucks of coal, and the handling of it at its destination. The system of mounting the tenders upon two four-wheeled bogies again commends itself in many ways. These and many other items about American engines are all more or less admirable, such as their balanced valves, and the numerous devices for cleaning out smoke-box tubes and boilers; but as they do not materially affect the case in point, they may be left out of the question at present.

It will be noticed in the *résumé* of the types of locomotives adopted by the various Australian Colonies that, wherever the American engine has been chosen as a standard, the engines have been locally built; in which case, when carefully modified to suit existing conditions, they become about as desirable an article as could be wished for. In but few cases, however, have repeat orders been sent to makers in America; and the reason is not far to seek. The many admitted advantages of the American locomotive are mitigated by the crude design of detail, and the poor quality of both material and workmanship. In this lies the objection of colonial engineers to engines built in America. Bar frames appear heavy, clumsy, unsuited to the work they have to perform, and wasteful of space—so limited on the standard gauge—are liable to fracture, and require endless attention. The haphazard manner in which all fittings, springs, levers, &c., are attached, give the impression that the engine had been constructed without any consideration of their being required, and the various workmen left to arrange their attachment as most convenient during erection. Endless work is caused to the staff of the running-sheds through this when the engines are placed in working order, as, after a run of 100 to 150 miles, a most careful inspection is found to be required, together with a general screwing-up of all bolts and nuts, and the replacement of any part that may have chanced to shake off during the journey—an occurrence by no means uncommon. This may be what is described in the Argentine Republic as "defects in a few small details which do not affect their conditions of service," but the cost of these continuous small repairs, and the danger caused by this insufficient attention to detail and workmanship, is not easily overlooked by the authorities responsible for the safety of the travelling public. The feverish haste of the American makers to rush through work is responsible for the deficiencies; draughtsmen have not time carefully to place all these details, nor the workman for that admirable finish of work so much admired in English manufacture. Symmetry in appearance is unsought and uncared for. Boilers are punched and their pipe connections made in a manner quite at variance with English practice. Axle-boxes are of the commonest design, the lubrication system wasteful, and the axles, as will be seen from the experience of New South Wales, where all the bogie axles were replaced at the Government works, small and with insufficient journals to secure cool running; collars are attached with set-screws, and excentrics without keys. In a word, while the principle and conception of American engines is good, the detail and execution are crude to a degree as regards those manufactured for export. In America, on the leading railways, a very different state of affairs exists; the engines are built either by the railway companies themselves, or by makers carefully selected, and to the specification of the superintendent of motive power, under his inspection. The quality of the engines is all the time being improved by the introduction of many and useful innovations not considered necessary a few years back.

Colonial engineers are at a disadvantage in America by not having a firm like that of Sir John Fowler, to whom they can entrust their inspection work, and thus ensure at least an honest article in return for their money. As the American locomotive builders become obliged to find an outlet for their manufactures abroad, their export trade having till now been a very secondary consideration, coming of an adaptable race they will no doubt endeavour to comply more closely with the standard of work required by the English and other Colonies. From the manner in which work can be carried out in this large and enterprising country, it is possible that the English makers will meet with a competitor of no mean order in the near future, unless they endeavour to modify their somewhat conservative ideas. It is by no means clear that either English or American locomotive builders have had a fair opportunity to build a typical colonial locomotive, as usually they are supplied with so little data to go upon, that as a natural consequence they supply the article with which they are most familiar. It can at least be said in favour of English firms of any standing that their work is trustworthy and of good material, even if not carried out under rigid inspection, and when they err, it is usually from ignorance of local conditions, coupled with the erroneous impression "that what is good enough for England is good enough for anywhere." When colonial locomotive engineers are able either personally or by deputy to visit the country where they propose to have their locomotives built, and to superintend the design, America offers large inducements, and it would be one of the most interesting departures in locomotive practice to see what could be produced under the joint superintendence of an English purchaser and an American manufacturer. To design a locomotive entirely suitable for English colonies requires thorough knowledge of local requirements, coupled with that insight into economical working and repairing which is possessed by few outside the pale of the leading English railways.

## ANTWERP INTERNATIONAL EXHIBITION.

### THE FRENCH EXHIBITS IN INDUSTRIAL HALL.

IN my last letter I described French exhibits in the Machinery Hall; but engineers who wish to compare the progress made by French mechanics and metallurgists with that of their Belgian and German competitors will have to visit the main building, where the iron and steel industries of France fill a larger space than they do in the Machinery Hall. Why the products of French rolling mills, together with their steel forgings, cannon, and shells, should be shown in a different building from similar objects made by the Société Anonyme de Couillet, or Messrs. Cockerill, it is not easy to see; but I have already pointed out that the absolute want of system displayed in the arrangement of exhibits is one of the worst features of this Exhibition.

Every engineer who visits Antwerp should inspect the calculating machine and other instruments shown by M. Léon Bollée, of Le Mans; but as his stand is surrounded by exhibits of art pottery and dress materials, many pass it without noticing, who would not fail to see it if it were in the Machinery Hall. The calculating machine is an apparatus 3ft. long, made chiefly of brass. By its means additions, subtractions, multiplications, divisions, squaring, and square-root can be made mechanically. It will multiply any number of figures up to 20 by any other number not exceeding 10. The figures to be multiplied are along the front of the machine, near the top, and above them is another row, in which the result is given. Over this is a tape marked "units," "thousands," "millions," &c., so that large numbers may be easily read without counting the figures first. When multiplying with decimals this tape moves automatically, so that the decimal point is always correctly placed in the result. The figures of the multiplier are arranged in another frame below. The machine in several test operations was always accurate, and it is very quick. The inventor says that with any numbers up to the machine's limits, he can do 100 divisions, 120 square roots, or 250 multiplications in an hour.

Another apparatus shown by M. Bollée is a railway ticket distributing machine. This is chiefly intended for use in small stations of branch lines, where the person in charge is not very experienced. The tickets are arranged in piles, according to class, in the compartments of a locked, glass-fronted box. At the side of the machine is a dial bearing the names of the stations. A handle is turned round the face of this dial, till a projection on it enters a slot opposite the name of the station and class. The handle of the machine is then turned, when a ticket comes out numbered and dated; a needle pricks the description of ticket on a register, and a counter marks the total value sold. By using this apparatus the person issuing the ticket has only to see that he receives the value marked on it; a travelling inspector merely requires to ascertain if the cash agrees with the figures indicated on the counter, which he can do in a minute whilst the train is stopping; and if, on account of illness or other emergency, the ticket clerk's work has to be taken over by another man, there is no need for the stock of tickets to be counted, as the newcomer can see the number of the last ticket issued, as well as the cash in the till.

Several different descriptions of cash registers are also shown, arranged for railway way-bills as well as for shops. One of these machines has a horizontal dial like that of the ticket-distributing machine, but with four or more sets of slots, numbered from one to nine. The machine exhibited is for francs and centimes; but they can be equally well made for English money. The handle is placed successively opposite each figure in the bill, and a lever struck each time. By turning another handle a ticket is delivered bearing the name of the firm, &c., amount paid, and date. The tickets are numbered consecutively, and, if necessary, can also bear the number of the department or employé. Another machine issues two duplicate tickets, whilst in another, duplicate copies of each bill are inscribed on a continuous roll of paper.

M. Bollée's most ingenious invention is an apparatus for ascertaining the note of tuning forks by the eye, instead of being obliged to rely on the ear. A fork, of which the note is known, is set horizontally, and the fork to be tested, vertically. The latter is blackened, and then a small spot at the end of one of the prongs is made bright. A strong ray of light is now thrown on the two forks, and they are made to vibrate. If their notes are the same, the vibrations will be isochronous, and the reflection of the light will form a circle. As the notes of the two forks differ, so the curve made by the ray of light varies in form. These curves are in some instances very complicated, but the same variation between the note of the two forks always gives the same curve. M. Bollée uses a fork with the note C as the standard, and by comparing the curve with a set of diagrams, the note of the other fork is at once known. He has also a machine for making these diagrams; bevel-wheels, whose teeth vary as the vibrations of the notes are put in, the handle turned, and the curve corresponding to the difference between the notes is drawn.

The Compagnie Française des Métaux exhibits a plate of aluminium, probably the largest which has yet been rolled, as it measures 18ft. by 5ft. and is $\frac{1}{12}$in. thick. It weighs 52 lb., and is intended for the French torpedo-boat Le Forban, now being built at Havre. This company also shows a series of aluminium angle bars for the same boat. They are all 18ft. long, and vary in section from 2in. by 2in. by $\frac{3}{16}$in. up to $2\frac{3}{4}$in. by $2\frac{3}{4}$in. by $\frac{1}{4}$in. Besides these there are cartridge cases and smaller objects also in aluminium. In copper the company shows fire-boxes for locomotives, a solid drawn tube 12ft. long, 3ft. 3in. diameter, $\frac{5}{16}$in. metal, weighing 25 cwt., a pan 10ft. 8in. diameter, 5ft. 3in. deep, weighing 24 cwt., and other tubes and pans of smaller size. Another branch of its manufacture is that of ornamental copper and brass tubes, fluted or embossed, round, square, or hexagonal in section, and gilt or bronzed. In steel it shows cartridges, a torpedo tube, &c. It also exhibits drawn steel and copper tubes for boilers with internal radial projections ("Serve" tubes), spiral copper tubes 50ft. long by 2in. diameter for distilleries; brass and copper wire, &c.

Messrs. Schneider and Co., of Creusot, have not such a large display as they have had at former exhibitions. They show several samples of steel, including a bar 6in. square, bent cold, and a 10in. plate, with the shells that have been fired at it, imbedded in it. Their chief novelty is a 3in. quick-firing gun, which can be loaded and discharged three times in a minute. When the cartridge has been inserted, the breech is closed, and the handle turned 45 deg. If not closed properly, or not turned so that a clutch on the handle will enter its catch, the gun will not go off. After firing, the breech is turned back, and the act of opening it causes the extractor to throw out the empty cartridge case. They also exhibit several other guns, a torpedo tube, with a guide slot top and bottom, and a good many models. Some of these are of different descriptions of turret guns, another is of a steel torpedo boat 120ft. long, and several are of engines. Amongst the latter is a very pretty working model of the triple-expansion engines for the s.s. Alger, 8000-horse power.

The Société des Forges et Chantiers de la Mediterranée exhibit a fine collection of Canet guns. The largest, of which it only shows a model, is 42ft. long, $12\frac{3}{4}$in. diameter, weighs 65 tons, and carries a projectile weighing 9 cwt. Three guns of this size were made in 1889 for the Japanese war vessels Matsushima, Itsukushima, and Hashidate, and were at that time the most powerful that had been made in France. The initial velocity is 2800ft., and they will pierce an iron plate 4ft. thick placed at the muzzle.

The maximum range is 12½ miles. The makers claim that these guns are equally powerful with those of 15¾in. bore made in England and Germany, and weighing 100 and 120 tons respectively. In the smaller sizes they show the actual guns, and explain the mechanism. Two of these are rapid-firing guns, of 4in. and 6in. diameter. The former is 26ft. long, has a projectile weighing 28 lb., an initial velocity of 3300ft., and will pierce a 20in. iron plate. The latter is 23ft. 6in. long, the weight of the projectile is 88 lb., the initial velocity 2400ft., and it will pierce a 19in. plate. Amongst the other guns shown are two of 4½in. bore. One of these, made for the training ship Zaragoza, belonging to the Mexican Government, has a length of 17ft., an initial velocity of 2300ft., takes a projectile weighing 46 lb., and will carry 7½ miles. The other, of the same diameter, is intended to be used in fortresses. Its length is 10ft. 3in., the projectile weighs 40 lb., the initial velocity is 1900ft., and it will carry 6 miles.

If there is one lesson that the Antwerp Exhibition teaches us more than another, it is that foreign manufacturers in many branches are not only able to compete with us in Japan, Brazil, Chili, Turkey, and other countries which once came to England for their supplies, but that they are even able to supply our Government and our private firms with goods that were once always ordered at home. Another striking instance of this is seen in some shells 15in. diameter and weighing 11 cwt., which have been recently made for the British Government by the Compagnie des Hauts Fourneaux, Forges et Aciéries de la Marine, of Saint Chamond, of whose magnificent exhibit they form a part. They are of chrome steel, and form a portion of a collection of shells supplied to foreign Governments. Amongst these are 13½in., 9in., and 6in. shells for Great Britain, 10in. and 8in. for the United States, and 12in. and 11in. for Russia. Chrome steel is also shown in the form of armour-plates. One of these, measuring 6ft. 11in. by 4ft. 10in. by 10in., was fired at by a gun 6¼in. bore, with gradually increasing charges, the weight of the projectile being 91 lb. When the shell struck the plate with a velocity of 2000ft. the penetration was 9½in., and at a velocity of 2200ft. it increased to 10½in. Another plate measures 5ft. 11in. by 3ft. 3in. by 1¼in. Eight 40 lb. projectiles were fired at this from a gun with 4¾in. bore. At a velocity of 490ft. the penetration was $1\frac{7}{16}$in., increasing to 2¼in. at 690ft. A plate 5ft. 3in. by 3ft. 5in. by ⅛in., intended for decks of war vessels, has been fired at with projectiles 3⅜in. diameter, weighing 11 lb., and at a velocity of 600ft., without being pierced. Other steel plates are shown, and also iron plates of various dimensions, which, for land purposes, are preferred by French military engineers to steel. A detailed list of the tests to which these have been exposed would be too long, but all the plates shown have been tried, some with four or five shots fired at the same spot.

In ordnance, its latest type is the "Eclipse," a disappearing gun for land batteries. The one shown is 5¾in. diameter and 11ft. 10in. long. The projectile weighs 44 lb., and the initial velocity is 1970ft. The back of the gun-carriage runs on a rail, whilst the front is supported on a pivot firmly secured to the base-plate of the carriage. This carriage runs on rails 4ft. 11in. gauge, to which at the moment of firing it can be fixed by four catches, and is practically arranged like the carriage of a travelling crane. The gun itself is carried on the upper end of a lever, which oscillates at one-third of its height on a horizontal axle held by the gun-carriage, and the lower end of this lever is connected with an hydraulic brake. Another support at the back of the gun moves with and remains parallel to the lever, so that the gun in rising does not change its inclination to the horizon. This angle, which is set whilst it is in its lowest position behind the parapet or screen, can vary from +25 deg. to −10 deg. The gun can be turned by hand till it is approximately in the required horizontal position, and it can then be finally adjusted by means of a pinion gearing into teeth on the inner edge of the roller path. The brake, which is the essential part of the invention, consists of two cylinders placed one above the other, with valves by which the connection between them can be opened or closed. The piston of the upper cylinder is joined to the end of the lever carrying the gun by two connecting-rods, whilst that of the lower cylinder is pressed down by a set of "Belville" springs, which are steel discs, slightly dished, and strung in pairs on a central rod. At the moment of firing, the upper piston forces the liquid into the lower cylinder and compresses the springs. At the end of the recoil the valve closes, preventing the return of the liquid, the springs remain compressed, and the gun eclipsed. It is in this position that it is loaded and pointed; and then, when ready, the valve connecting the two cylinders is opened and the springs expand, and bring the gun up into its position for firing. If necessary, it can be raised and lowered without being fired. The difference in height between the loading and firing positions is 4ft. 1in.

Another gun shown is a 3in. bore rapid-firing field piece, in which nearly the whole of the recoil is taken up by the hydraulic brake and the springs. In one tested recently it was found that, after being discharged ten times, the total recoil was less than 4in.

The chief attraction at this stand is a full-sized revolving steel tower, carrying a gun 5ft. 6½in. long, 4¾in. bore. The upper part of the tower is formed of cylindrical armour-plate 8ft. 6in. diameter and 4¼in. thick, roofed over with a spherical plate 6in. thick. The embrasure is in the cylindrical plate, and the spherical roof plate oscillates with the gun-carriage, and causes the eclipse. The oscillation is produced by a balance weight on the platform which supports the gun-carriage, being raised or lowered by means of a winch in the chamber below. When ready for firing, the gun is run out till the muzzle projects 3ft. beyond the embrasure; its position can then be varied 3 deg. to the right or left without moving the tower; it can also be lowered 5 deg. or raised 30 deg., either in its firing position or when eclipsed. To prevent accidents, there is a special arrangement by which the gun cannot be fired until in position with the carriage firmly fixed; nor can the eclipse take place till it has been run in from the embrasure.

Besides the full size tower, three working models are shown, each to carry two guns of 6in. bore. Another part of the Saint Chamont Company's exhibit consists in steel castings. It shows some valves, &c., for marine engines, cylinders, bends, tooth wheels and other pieces. In rolled steel it exhibits plates and bars, many of which have been subjected to the usual tests of being twisted or bent cold; and various sizes of rolled joists, up to 26½in. by 5¾in. by 1⅜in.

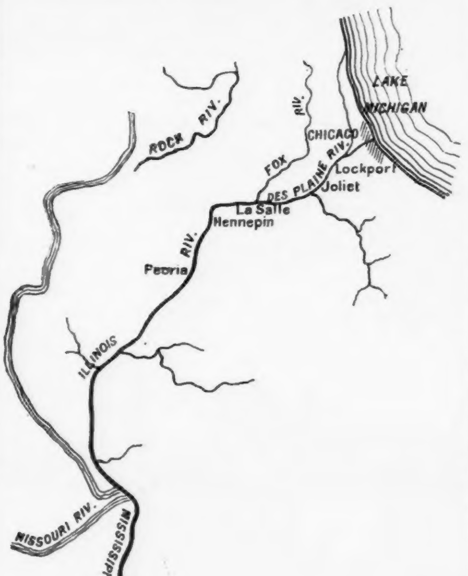
Adjoining the Saint Chamont installation, and scarcely inferior to it in size, is that of the Compagnie des Forges de Chatillon et Commentry. Like its neighbours it shows a full-sized turret. It is rather larger than the other, being for a gun 8¼in. bore. It also shows several models of turrets for weapons of various sizes, from one for two 9½in. guns, 28ft. long, down to a turret for a single 2in. gun. In steel castings it exhibits a gun carriage frame, and a screw for a torpedo boat; and in rolled steel, a series of armour-plates from 3in. thick, down to $\frac{5}{32}$in. Another of its exhibits is steel torpedo netting, of which it says it has made nearly all that is used in the French navy. Finally, it shows some forged steel shells with copper rings, the largest being 16½in. diameter, and some chilled cast iron shells up to 11in. diameter.

Amongst the French rolling mills which are not also exhibitors of artillery, the Forges et Aciéries du Nord et de l'Est have the largest display. They show locomotive and wagon axles in Martin-Siemens steel; joists, angle, T, and channel bars in basic Bessemer steel; steel rails varying from 9 lb. to 90 lb. per yard; and pieces split, twisted, and hammered flat with a 10-ton hammer.

Similar exhibits, but only in iron, are made by the Société de Ferrière-la-Grande and the Société des Hauts-Fourneaux de Maubeuge. The latter make a speciality of a joist with two longitudinal grooves on the under side of the bottom flange, intended to form a key for plaster on ceilings. There are many other French exhibitors of rolled iron and steel, axles, and other forgings, but they occupy less space, and their exhibits are less varied than those of the firms mentioned above.

## THE CHICAGO SHIP CANAL AND DRAINAGE CHANNEL.

A work, which if not entitled to rank in importance with the Manchester Ship Canal, yet is entitled to notice both from an engineering and commercial point of view, is now in operation for the purpose of effecting a waterway for ships of considerable size between Lake Michigan and the Illinois River. The primary object, however, for which this work was undertaken was the conveyance of the sewage of the city of Chicago, and it may certainly be classed as the largest outfall sewer that has ever been constructed. A short description of the physical character of the district and the circumstances which have led to the cutting of this waterway will make the description of the work now in hand more clear.



Chicago stands on the watershed which parts the waters flowing on the one side to the Mississippi and the Gulf of Mexico, and on the other to the St. Lawrence. The geological character of the strata indicates that the outlet of the great lakes was at one period westward, through a river two miles wide and 150ft. deep. Between Chicago and Joliet is a valley, the bed of which is rock, but which is now filled up with alluvial deposit. As the surface of the waters in the great basin of the North American lakes fell below the rocky bed of this valley, the flow westward was stopped and the St. Lawrence became the sole outlet, the valley being subsequently filled with glacial drift. A very slight change of levels would again allow the water from Lake Michigan to flow westward. At Lockport, thirty miles from the south shore, the lake level is reached; the fall then becomes rapid. At Joliet, ten miles further, the fall is 77ft., and at La Salle, 100 miles from Chicago, where the Illinois River is met, the total fall reaches 146ft. This river, after a course of 225 miles, joins the Mississippi. The construction of a canal from Lake Michigan to the Illinois, and the rectification of this river, will open up a waterway from Chicago to the Gulf of Mexico, making it thus the main port for traffic both from the East and from the West. This fact was realised in the earliest days of settlement of this part of America, and Joliet, who discovered the Desplaines Valley in 1673, reported that it would be quite practicable to make a canal so that vessels could pass from Lake Michigan to the Desplaines River, which runs from the summit level to the west of the lake to the Illinois. From that time forward the matter has been constantly brought forward. In 1795 a treaty was made with the Indians by which a free passage by land and by water was secured from the mouth of the Chicago to the commencement of the portage between that river and the Illinois, and down that river to the Mississippi. The subject was once more brought before Congress in 1804, and a survey ordered. The result of this was to show that the bed of the Desplaines was rock, and from 7ft. to 10ft. higher than the surface of the lake. The scheme, however, was considered practicable, and in 1836, with the aid of a grant from the Government, the State of Illinois made a commencement of the construction of a waterway. The width of the channel was 60ft., and depth of water 6ft. The summit level, 22 miles in length, was 8ft. above the lake. After spending about a million of money, the deep cut of 15ft. through the rock, originally intended, was abandoned, and the canal, 100 miles in length, completed in 1848 on a higher level, at a cost of about 1½ millions. In 1871 it was deepened across the "divide," or rocky summit, sufficiently to create a flow of the water by gravitation from Lake Michigan, and to carry away the sewage from the city. For a few years this canal served well both for commercial and drainage purposes. A few years, however, after the deepening the population of the city had so increased, and the amount of sewage sent down the canal became so great, that its water was excessively foul. Pumps were therefore put in operation to raise water from the lake, and thus to create a greater flow of water. As the population continued to increase the nuisance from the sewage became worse, and by backing up into the lake at times polluted the water supply of the city, which was obtained from it. To meet this a tunnel was sunk under the bed of the lake for a distance of four miles from the city, from the end of which the supply was drawn. But even with this precaution, under certain conditions of the wind and weather, the purity of the supply was affected. In 1882 the States Government authorised surveys for the purpose of enlarging the existing canal, and for improving its connection with the Mississippi, and for making it of sufficient size to take vessels of 600 tons. The City Council of Chicago also appointed a Commission in 1886 to report as to the best means of dealing with the sewage. This Commission reported that means must without delay be taken to prevent the sewage of the city flowing into the lake if the water supply was to be taken from it; that it was not practicable at any reasonable cost to deal with it by land irrigation or chemical treatment; and that the only effective way of dealing with it was by a channel down the valley of the Desplaines to the Illinois River, its section being of such an area as to take a sufficient volume of water from the lake to dilute the sewage, so that it should not be a nuisance to the people living in the district through which it passed. Under present conditions, as the sewage flows down the existing canal it passes through Joliet, a city of 25,000 inhabitants, and other towns of smaller size. The offensive condition of the water arising from the sewage of 1½ millions of inhabitants can be traced as far as Peoria, 120 miles from Chicago.

Finally, in 1889, the States Legislature decreed that the construction of a combined drainage and navigation channel between Chicago and Joliet should be undertaken. At the latter point it was assumed that the river would be able to receive and dilute the combined sewage and lake water until plans were completed for the continuance of the navigable channel. This was the origin of the waterway which is now being constructed, and which will be as large as a modern ship canal, and will provide a waterway for the largest lake and river steamers.

The quantity of water that will pass through the channel is put at 10,000 cubic feet a second, moving at a velocity of three miles an hour. It is an interesting question as to what will be the effect of so large a diversion of water, about 4½ per cent. of the total amount that now passes through the St. Clair River, and thence over Niagara to the St. Lawrence. The average variation of the level of the lakes is from 18in. to 24in. during the year, and the loss from evaporation represents a difference of 6½in. in water level. It is estimated that a discharge of 10,000 cubic feet a second into the new canal will lower the level of the four lakes 2·87in. a year. It is the opinion of the engineers who have investigated the subject that when the variations due to wind, evaporation, and rainfall are taken into consideration, the effect of the water which will be abstracted will not be noticeable.

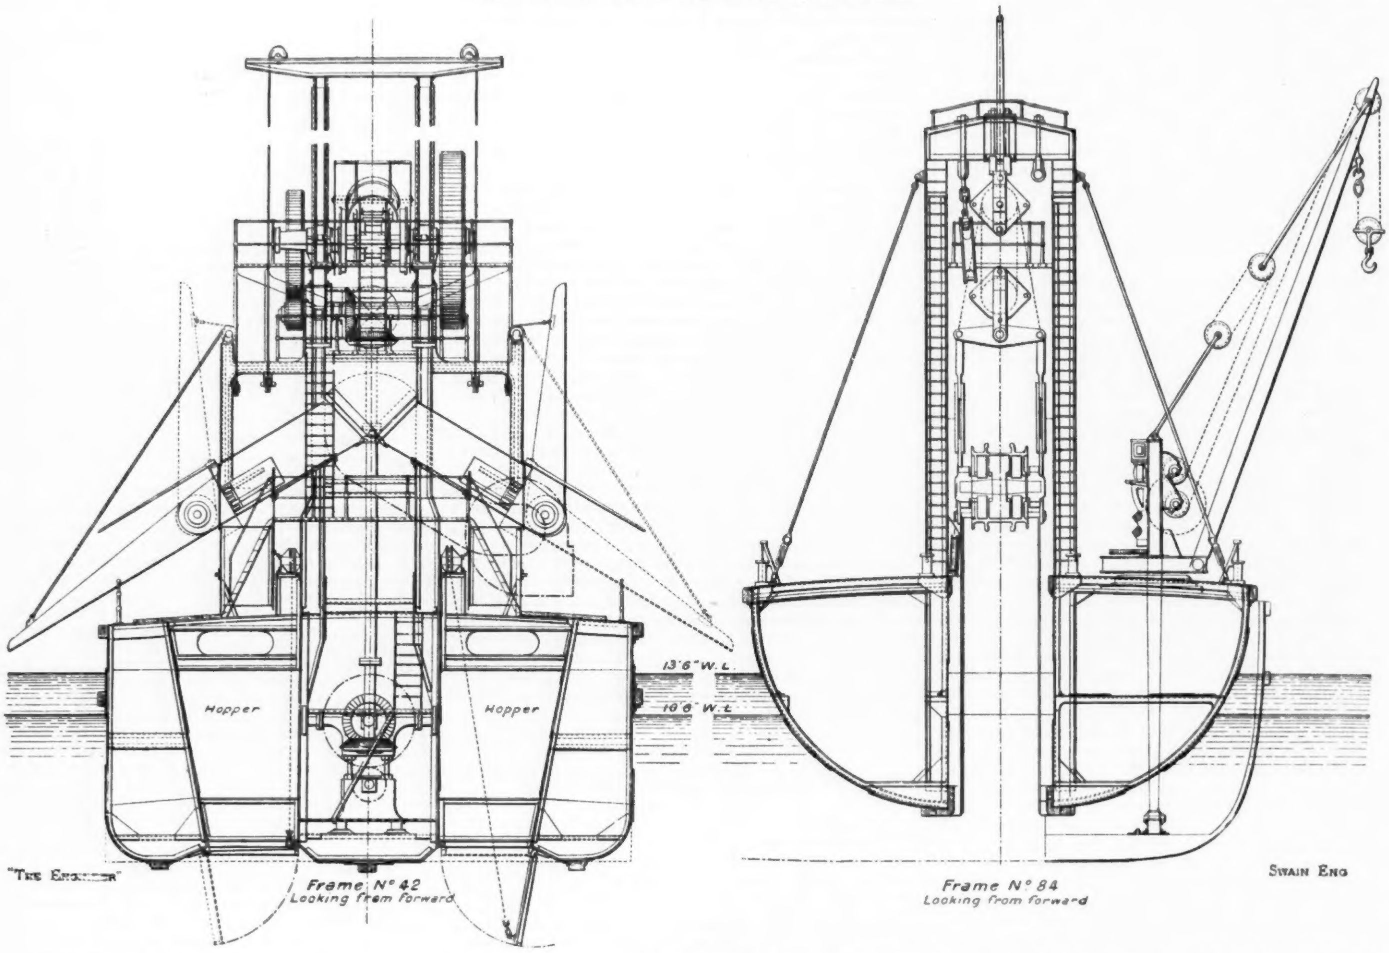
The course of the new channel runs nearly south-west, and at about nine miles from Chicago enters the Desplaines Valley, following the course of this valley for the remainder of its length of about forty miles, till, at a short distance below Joliet, it joins the Desplaines River. Before commencing the excavation of the canal it was found necessary, in order to control the fluctuations of the river, to construct a diversion of thirteen miles of new channel, and to erect thirteen miles of banks to separate the river water from that of the canal. It was also necessary to construct a concrete dam or spillway 367ft. long and 16ft. above the water level at Lake Michigan, to allow surplus water to flow towards Chicago. The width of the bottom through the part where the clay exists is 202ft., and of the other parts 110ft. About twenty miles of the canal is through rock or hard material, and this part will be 160ft. wide at the bottom, with vertical sides; the depth of the bottom from the surface of the earth being from 30ft. to 35ft. The depth of water throughout will be 22ft. The quantity of glacial drift to be moved will amount to 25½ million cubic yards, and of solid rock nearly 11 million yards. The price at which this material is being removed by contract is from 10d. to 15d. for the drift, and from 3s. to 3s. 7d. a yard for the rock.

The works were commenced in 1892, and are expected to be completed in 1896, and the cost is estimated at 5¼ millions of money, while a further sum of about four millions will be required to improve the navigation of the Illinois River below the junction of the new canal. When this is done there will be an unobstructed navigation throughout the 227 miles of the lower part of the river, sufficient for the largest class of Mississippi steamboats, to Utica. Above this a fall of 140ft. will have to be provided for by locks.

Road Bridge for Brazil.—The following corrections have to be made in the article on this bridge which we published in our last impression:—On the 23rd line of second paragraph, page 252, instead of "dead load" read "live load without balance weights;" and in the 4th line, 3rd column of the table of stresses, instead of 116 3 read 216·3.

# THE SOLID ROCK DREDGER MAJESTIC

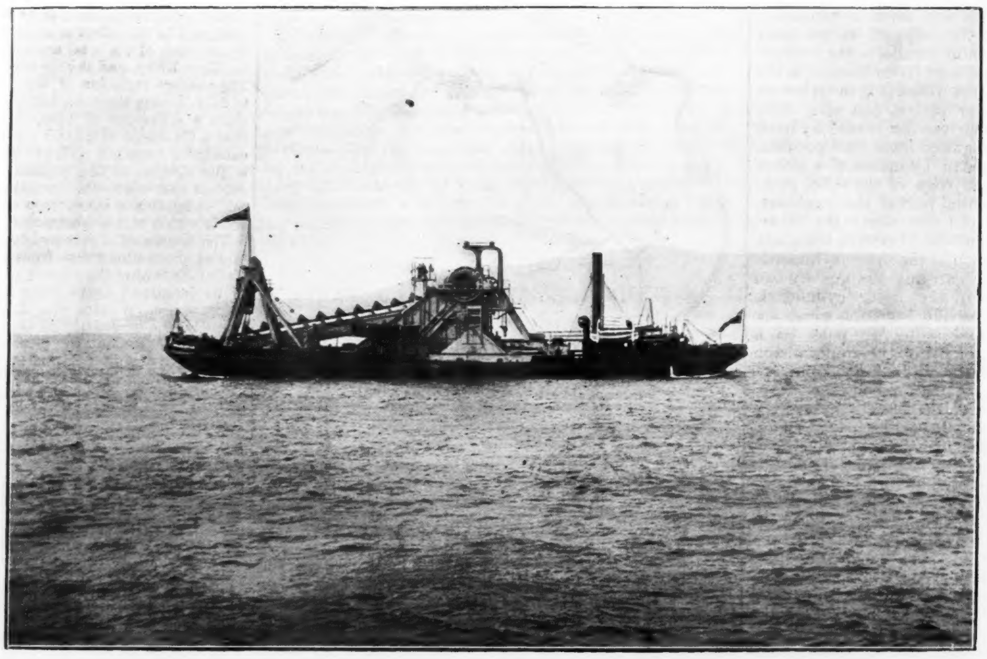
MESSRS. LOBNITZ AND CO., RENFREW, ENGINEERS



## SOLID ROCK DREDGER.

At the time when the entrances to most of the leading harbours and docks of the world were made, they were of ample capacity for the admission of ships of the heaviest burthen. Gradually, however, the tonnage and draught have been increased to such an extent that on the score of safety as well as of convenience it long since became necessary to deepen and otherwise improve these channels. In many instances the entrances have been cut through the solid rock, so that the work of deepening has proved very expensive, and has occupied a long time. Blasting had first to be resorted to and the spoil then dredged up. In some instances the entrances are situated in the open seaway, thus rendering the work increasingly difficult, and protracting the time of its execution. Step by step the strength and power of dredging plant have been increased, so that in some instances the solid rock has been successfully dredged with little or no blasting. In this way the new channel for the harbour of Alexandria was formed by Messrs. S. Pearson and Son, of Westminster. It was a heavy job, being a cutting in the open seaway 300ft. wide, through a series of ridges of solid rock, and running out about a mile from the harbour. The work, however, was satisfactorily accomplished, practically without blasting. Having disposed of the dredger used at Alexandria, and having taken a contract for cutting a channel through the rock at Bermuda, Messrs. Pearson and Son have had another dredger designed, into which they have introduced all the improvements suggested by their experience in previous contracts of this nature, and which is the strongest and most powerful dredger afloat. The vessel has been built, engined, and fitted by Messrs. Lobnitz and Co., of Renfrew, where we were recently afforded the opportunity of inspecting it. By the courtesy of Messrs. Pearson and of the builders we are enabled to illustrate this dredger very fully in our double page engraving this week, and to give particulars of its construction.

The dredger has been built entirely of steel, and is capable of steaming to any part of the world at a speed of 7 knots an hour. In the after peak is a water-ballast tank to carry about 100 tons, and which may be arranged for use as a fresh-water tank and a ballast tank. It is divided by a steel deck with a water-tight manhole so as to carry spare gear in the top compartment, which, however, will also be available for water when required. She is propelled by four-bladed twin screws, right and left-handed, and of 9ft. diameter, which are driven each by its own independent triple-expansion engine, the two representing 800 indicated horse-power. Steam for these and the dredging engines is supplied by two cylindrical steel boilers of the return tubular type, the two representing 1000 indicated horse-power. They are arranged independently, so that one may be cleaned whilst the other is in use for dredging. They are fitted with Fox's suspension flues, and their working pressure is 160 lb. per square inch.



THE MAJESTIC IN THE CLYDE

The dredging gear is of a very massive and powerful character, and is of sufficient strength to pull up the engine should any impediment be met with in the working, by which means the risk of a breakdown will be avoided. The ladder is a strong girder of the box type, with chilled rollers for carrying the bucket chains. A special point here is the manner in which the suspension shaft of the ladder is fixed on the incline of the framing with buffer gear. An elastic buffer 20ft. long, and of special construction, is provided on the incline of the framing on each side. It consists of a series of powerful spiral springs which can be adjusted to take the strain equally and without damage to themselves, and having a combined resistance of over 100 tons. When dredging hard material in a moderate swell, with the vessel rising and falling, the shocks to the bottom tumbler will be cushioned to such an extent that work can be carried on continuously without the liability to serious accident to which ladder dredgers are subject in these circumstances. Buffers have, of course, been used before in this connection, but their construction has usually caused them to give as much trouble as was previously experienced without them by breakages of the dredging gear. The pins of the bucket chain have 3ft. 4½in. centres, this large pitch being adopted with a view to dredging hard coral or other similar rock. Some idea of the massive character of this part of the machinery may be gathered from the fact that one element, *i.e.*, a bucket and one pair of links, weighs over two tons. The total weight of the chain of buckets is 60 tons, and with the ladder the weight is 100 tons. The pins and wearing parts in the bucket chain are of manganese steel, working in bushes of the same metal. The links are built up of three thicknesses of rolled steel of special quality, by which arrangement the liability to trouble from defects from internal flaws is obviated and other advantages are secured. When dredging at six buckets per minute, there will be a strain of 100 tons on the bucket points. The ladder is lowered and hoisted by forward shears with eight-sheaved chain blocks, worked by a powerful ladder-hoist winch, with independent steam engine. Although the dredger cuts her own flotation—that is, cuts her way through a bank above water-level—and has a closed bow, she still has the advantage of being able to raise her ladder and bottom tumbler above deck level through the well. In ordinary work the vessel can dredge to 35ft. below her light load line, but by making use of a guide wheel for taking up the sag of the bucket chain, she is able to dredge to a depth of 45ft. when required. As will be seen from our engraving, the dredger is fitted with overhead gear on top of the main framing, so that she can do her own heavy repairs, independently of assistance from the shore. The heaviest pieces of machinery can be moved about by the aid of steam winches placed fore and aft. The dredging apparatus is driven by a compound engine of special construction, with 16in. and 30in. cylinders, and 2ft. stroke, and which is arranged to meet any sudden changes of power. The bucket chains are driven through treble gearing, so arranged as to be capable of giving three different speeds to the buckets, with the same number of revolutions of the engine, this being effected by means of change wheels.

When dredging rock the spoil falls from the buckets with great force from a height of about 15ft. on to a flap-valve, which breaks the fall and regulates the loading into the hoppers, of which there are two, one on either side of the vessel. This valve consists of a thick armour-plate which normally rests at an angle of about 45 deg., and receives the shocks of the fragments of rock, some of which weigh upwards of a ton and a-half, and so prevents injury to the shoots. The valve, which forms a lid to either shoot alternatively, is worked by steam power, and is so arranged that either shoot can be closed or opened in order to regulate the loading of the hoppers into which the spoil is delivered fore and aft from the shoots by means of breeches pieces. Each hopper is capable of containing 7000 cubic feet of spoil, and when both hoppers are full the vessel will steam out to sea and discharge in the usual way. The hopper doors are built up of very thick steel plates on channel girders, and are opened and closed by special winches. The doors when closed are 1ft. clear above the grounding keels, so that they are well protected from injury by touching the bottom. The grounding keels and under-water fenders are of greenheart, to resist attacks of the *teredo navalis*. Should it be desired to load the spoil into barges alongside, the hoppers can be shut off from the side shoots, and hinged prolongations of the latter lowered by steam power for use. The vessel is also fitted with a centrifugal spoil pump for soft dredging, and she can discharge the spoil on to land through a spout. This pump will be driven by the propelling engines through rope-gear, and will absorb from 350 to 400-horse power, according to the distance to which the spoil has to be delivered. There is also an additional centrifugal pump which discharges a supply of water into the shoot at the top tumbler, and likewise delivers water into the discharge pipe of the spoil pump. The water thus assists in breaking up the soil, and acts as a carrier for it. It will thus be seen that the dredgings can be discharged either into the hoppers, or into barges alongside, or into the spoil pump.

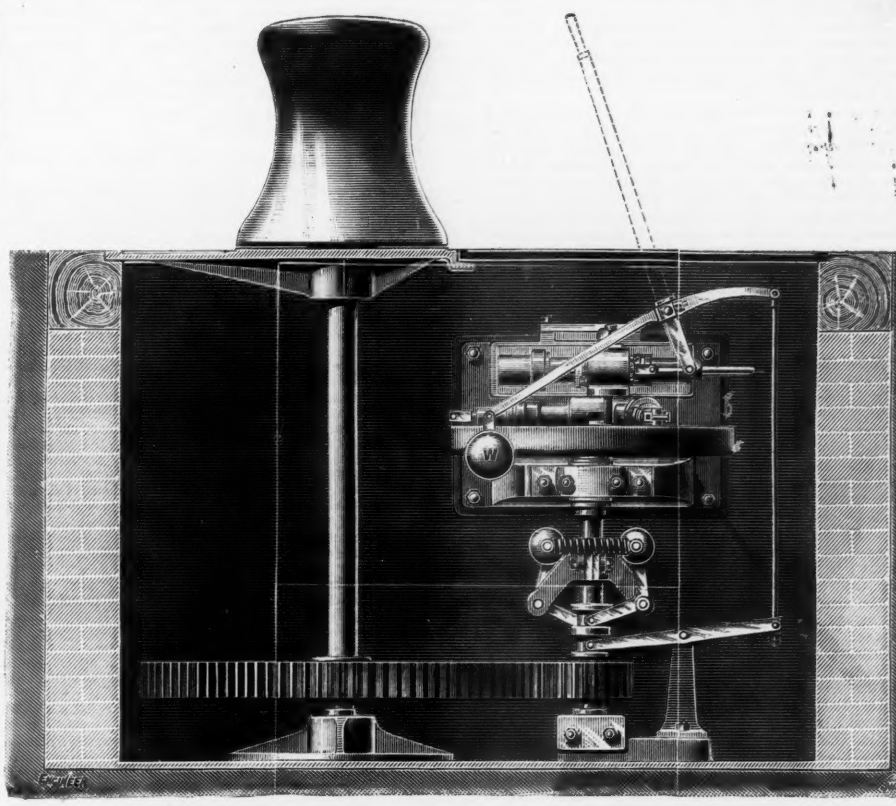
In addition to the dredging appliances, the vessel will carry a rock-breaking apparatus, which will be fitted forward as shown in our engravings. The rock-cutter is an iron bar weighing ten tons, and having a hard steel chisel point. It will be worked by means of a special steam winch and steel wire rope fitted with a monkey clutch, and will be operated after the manner of a pile driver. It is intended for use should any specially hard rock be encountered, which will be broken up by it ready for the dredger buckets to follow and pick up. The dredger carries a ten-ton deck crane with a sweep up to 35ft. radius. She also has powerful manœuvring winches at both bow and stern, each having three independent chain barrels. She is fitted with steam steering gear, which can be operated from the upper bridge and from the lower or navigating bridge. It can also be worked by hand should the steam gear break down, and, should these means fail, the dredger can still be steered by a steam winch. Special workshops are fitted up on board, so that all ordinary work can be done without outside aid. Besides all the usual hand tools, the workshops are fitted with various descriptions of lathes, planing machines, and drilling machines, and there is also a well-appointed smithy.

For ordinary service the dredger will carry 100 tons of coal, but her bunker capacity is 600 tons, which supply she will take in on long voyages. She will be fitted up with the electric light throughout, and will also carry a search light, so as to enable her to pass through the Suez Canal or any other similar channel by night. She will have on board a powerful steam launch as a tender, besides a complete outfit of all kinds of boats. There will be ample accommodation for the officers and crew, and she will, in fact, constitute the best appointed and most powerful dredger ever constructed, and will cover a wide range of usefulness. She has been built to Lloyds' and the Board of Trade requirements as a sea-going vessel, and was launched in February.

The following are the leading dimensions :—

| | Ft. | in. |
|---|---|---|
| Length between perpendiculars | 200 | 0 |
| Length over all | 208 | 4 |
| Breadth moulded | 39 | 0 |
| Depth moulded | 17 | 3 |
| Shear, forward | 4 | 0 |
| Do. aft | 3 | 0 |
| Round of beam | 0 | 9 |
| Draught light, in working order | 10 | 6 |
| Do. loaded, 700 tons in hoppers | 13 | 6 |
| Do. light, with ballast tank full, aft | 13 | 6 |
| Do. do. do. forward | 8 | 0 |
| Displacement, loaded | 2000 tons. | |

RIGG'S GOVERNED HYDRAULIC CAPSTAN



## HYDRAULIC CAPSTANS.

By Mr. ARTHUR RIGG.

HYDRAULIC capstans as hitherto constructed are wasteful in their use of pressure water, actually taking more when running unloaded than when performing their full work. It is mainly from this cause that there has been comparatively little extension in the use of hydraulic engines, and as the governing arrangement now to be described proportions the quantity used according to the demand for power, there is now no further reason why the application of these useful and convenient motors should not become greatly extended.

The hydraulic power supply companies practically restrict their sphere of operations to working lifts and cranes, as their pressure water is so much more costly than gas or steam power, and few opportunities occur where this convenient but costly power can be used for anything else. It does not seem to have occurred to these companies that it might pay much better to supply a cheaper power for a more extended class of customers than to keep up the out-of-date system of high prices and restricted output. As if to handicap still further the use of such hydraulic engines as have been hitherto put up, they use the same quantity of water when running at the same speed whether there be a full load or none, thus comparing in extravagance with a steam engine provided with a throttle valve, and using steam throughout its stroke. Any arrangement, therefore, by which the stroke can be altered in proportion to variations in load improves the economical working of hydraulic engines much as the working of steam engines was improved when an earlier cut-off gave the advantages derivable from expansion. What with the original high cost of water pressure, and its wasteful application, it is not surprising that hydraulic engines have not, up to the present time, become generally used for obtaining power, although their extreme convenience as compared with gas engines or steam engines is allowed on all hands. Before a governor can be applied, it is necessary to arrange for a variable stroke, which cannot well be managed with an ordinary crank. A reduction of speed seems the simplest method for regulating power, but as a uniform speed is so generally required, very few cases occur where this plan can be followed. For cranes or hoists regulation may be carried out by providing two or more rams and a system of valves, whereby one or more rams can be put into action, thus giving relatively proportionate powers. Such systems, however, are inapplicable to engines turning shafts, or at least they would be so inordinately costly and complicated as to preclude their general use, and an alteration in stroke remains the sole convenient and practical method whereby hydraulic engines can be satisfactorily regulated, and the speed maintained at a uniform rate.

In spite, however, of such drawbacks accompanying the use of hydraulic engines, great numbers are used at railway stations, docks, and other places, for driving capstans, and the surpassing convenience of such an unfailing power, so easily distributed, is found to compensate for the waste attendant upon its use. In order to mitigate, in some degree, the losses which occur when such capstan engines are running unloaded, it is usual to design their ports and passages extremely small, so that friction through them shall prevent too rapid a current, and also shall limit the speed at which the capstan can run when unloaded. Then the reciprocation of their rams frequently reverses the current of water, and this operation entails a series of destructive shocks upon the engine. Nevertheless, the combined effect of insufficient passages, and the reversal of currents at a tremendous pressure, imposes a limit—of utterly unscientific and wasteful character, it is true—upon the speed at which such capstans can be driven.

Capstan engines are made with two rams, having cranks at right angles, or with three cylinders, acting on the same shaft and cranks at 120 deg., so that they will start when water is turned on; and their dimensions are such as to provide an ample reserve to start a load beyond the nominal power at which they are intended to work. If we take the case of a capstan engine driven by three single-acting engines set radially around the same crank and at 120 deg. to each other, it is well known that the crank receives a tolerably uniform tangential effort, and a fairly regular movement ensues. But because of the crank turning round it is highly inconvenient to alter its radius; for this has already been attempted with results by no means successful from a practical point of view. If, now, we regard the same three-cylinder engine as having its crank centres fixed, so that when pressure is turned on the pistons will drive the capstan by revolving round the main shaft centre while the cylinders revolve around the crank centre, we get exactly the same results as to power by the ordinary system with more than one very distinct advantage. As the crank has now become stationary, it is easy to move its centre nearer or further from that of the main shaft, and all difficulty as to its regulation is at an end. If the crank centres be 3in. apart, then the stroke becomes 6in.; but if these centres be closed together until only 1in. apart, then the stroke becomes 2in., and there is the further utility in being able to alter the stroke, that by transferring the crank centre to that opposite the main shaft the engine reverses.

Having secured this mechanical convenience, it is no longer necessary to contract the area of water passages, for these can be made as large as desired, and the arrangements for governing, by altering the stroke, are all that remain to be carried out. There is now no appreciable loss by friction, and the full pressure may be admitted under the rams, and the speed can be maintained constant, while the power can be regulated in a thoroughly scientific manner by causing the stroke to vary as the governor balls move in or out. As a considerable pressure is required to move the centre carrying the cylinders, it is necessary to provide a supplementary engine, as a "relay," to perform this duty, leaving the governor to move its valves, and so determine how long the stroke shall be with any current load, and the engine running at any predetermined speed. The method by which this operation is carried out is shown by the accompanying illustrations.

This figure shows a three-ton capstan driven by a revolving engine, with the general arrangements of its governor —an apparatus of any ordinary kind. When the intended speed has been reached, the governor balls extend themselves, and through the intervention of levers and connecting rods, the valves of the subsidiary engine are actuated, so as to shorten the stroke of the main engine until it runs at any speed for which the governor has been arranged. The same speed is kept up while winding slack rope, and as this can now be made much faster than usually permitted with other capstans, a very adequate control is maintained and the capstan quickly gets hold of its load. As the rope tightens speed reduces, and the governor balls close together, permitting the weight W to descend and act upon the valves of the subsidiary engine in such a manner that the main engine has its stroke increased, and the hauling power of the capstan shows a corresponding augmentation, even until its full available power may be brought into operation.

In hauling vessels, a curious effect is shown by the capstan running at a high speed at about one-third stroke while drawing in the slack rope; then it acts with full energy until the load begins to move, and afterwards keeps changing between its shortest and longest stroke, as the cable tightens or slackens. Thus the governor keeps up a constant watch, and always regulates the stroke according to the load, however that may alter. As the capstan runs unloaded at one-third stroke, it may fairly be assumed that the average quantity of water used will, at most, be under one-half of that which would have been used had the hydraulic engine been unprovided with any governing arrangements. As three tons, moved at the rate of 60ft. per minute, requires at least 20-horse power exerted by the main hydraulic pumping engines, it is obvious that any contrivance by which this demand can be reduced to one-half represents a somewhat important economy, and one that justifies any additional cost of a secondary engine, with its valves and governor to gain. It means a saving of one-half the existing engine power, or doubling the number of capstans that might be employed on a railway or docks driven by the same power; and as it is well-known current expenses very soon represent an enormous interest upon capital, such a saving at so moderate an expense is a thing that, in the present days of keen competition, no company can afford to neglect.

It is sometimes useful to have the power of reversing a large capstan, particularly when new cables are being used. These sometimes acquire a kink which cannot be quickly released, and it may become necessary to cut and sacrifice a new cable to let a vessel go free. By reversing the capstan, however, a cable can be released, and the handle—shown dotted—is intended for this purpose. The governor acts only for the usual direction of hauling, but does not act when reversing is adopted for a few moments in order to release a cable. As there are no reversals in the direction of currents when driving one of these engines, it follows that there are no severe shocks in running, and this fruitful cause for the destruction of packings, if not for the breakdown of engines, is absent in those of the revolving type. If the water should not be flowing into one cylinder, it will be flowing into another, and that which is in any one cylinder when the inlet closes revolves with it at a considerable velocity, and in no case is brought to rest, as in any other type of engines with reciprocating pistons. It is this evil caused by stopping and starting a column of water, which so quickly injures the packings of those engines where such shocks occur. In the revolving type either cup leathers or ordinary packing glands can be used, and both are found extremely durable. The cylinder bosses and valve faces are somewhat peculiar in their construction. Their external packings are made of hydraulic leather, and there is a piston within the boss of that cylinder which is furthest from the valve face for the purpose of pressing all the bosses together, and for resisting any pressure against the face of No. 1 cylinder that would tend to force it away from the valve face. By the operation of such a balance piston, all the cylinder faces are retained in proper easy contact, and waste is prevented.

These engines have been running for many years, and although the relay engine, with its valves and governor, may seem somewhat complicated to those who see it for the first time, these additions are by no means so intricate as the Corliss or any other gear used for a like object—the economising of power in the use of steam; and as the cost of water power from an accumulator is necessarily greater than that of the steam power by which its pressure is obtained, it follows that the economical use of water is of correspondingly greater consequence than the economical use of steam.

## APPARATUS AT THE LONDON PHOTOGRAPHIC EXHIBITIONS.

Next Monday, when the Photographic Salon opens its doors in Piccadilly, there will be four photographic exhibitions running in London at one time, three of them of the major description. This position is unprecedented in the history of photography, and tends to show how its popularity has been increasing of late years. The salon devotes itself exclusively to the artistic side of photography, and does not exhibit apparatus. The annual exhibition of the Photographic Society—now the Royal Photographic Society—has on view as usual both photographs and apparatus. It opened last Monday. At the Aquarium at Westminster there is a miscellaneous exhibition devoted to nearly every phase of photography; it began about a fortnight ago. A fourth exhibition, that of the Central Photographic Club, is about to be opened near Covent Garden, of the photographs rejected by the Salon and the Royal Photographic Society, and all the specimens sent in will be hung without restriction.

Last Tuesday night, at a meeting of the Royal Photographic Society, Pall Mall East, under the chairmanship of Mr. Andrew Pringle, the makers of the apparatus placed on view described what were claimed to be the merits of their respective exhibits.

Mr. T. R. Dallmeyer described a new modification of his telephotographic lens, by which it is made suitable for long or short extensions of the camera within certain limits, so as to give the power of obtaining at will a large or small amplification of distant objects. He said that the main point with lenses of this class is the question of rapidity; it is easier to make a telephotographic lens at the sacrifice to some extent of the luminosity of the image upon the sensitive plate. He also exhibited his new naturalist's camera, a long narrow instrument of light weight, made chiefly for photographing wild animals from a distance when the camera is held in the hand, or when it can be partially rested against a tree or other fixed object, or when lying on the stomach on the ground. It is a long camera of light weight, preferably fitted with a telephotographic lens, acting upon a sensitive plate of somewhat small size. It has a lengthy eye-piece mounted upon its upper surface, and when this is adjusted to suit the eyesight of the user, it need never be shifted from that adjustment for the particular user; the image on the plate being at the same time in focus, it is never necessary afterwards to alter the adjustment of the eyepiece, for all the objects he sees in sharp focus through it will also be in sharp focus upon the plate. To minimise vibration a particularly light spring had been made for the instantaneous shutter by Messrs. Newman and Guardia, who, he said, had aided him considerably over the mechanical details. He was asked whether the length of the camera and the long focus of the lens did not add an extra amount of unsteadiness when it was used as a hand camera, and he replied that with a shorter camera more unsteadiness is probable, because then the user is more in the position of a man who is manipulating the short end of a lever. Mr. Fox Shew thereupon remarked that recently he had been using as a hand camera a long one with a telephotographic lens while standing, and resting it upon his left arm; he was taking no particular care, but obtained four images sharp out of six exposures.

Mr. Shew, on behalf of Messrs. J. F. Shew and Co., exhibited one of his hand cameras, the one which he uses himself, and which has adjuncts enabling it to take several classes of photographs. It can be employed as an ordinary fixed focus hand camera; it has also an attachable extension which doubles its length; it has likewise an extra front enabling it to be used as a stereoscopic camera, or for taking two lantern views upon one plate. The different parts will go into suitable side pockets, or can be carried together in a small case. He exhibited a variety of his type of hand or stand cameras, including one called the "Featherweight," with aluminium fittings, and weighing 17 oz., half-plate size, exclusive of the weight of the focussing screen. Fig. 1 represents one of his hand cameras mounted on the top of a stand, and fitted with a roller blind shutter working next the plate, and with a pneumatic release. Fig. 2 represents the same camera closed. We may mention that roller blind shutters working next the plate are theoretically of the highest class for allowing the maximum of light to pass in the shortest time; while they are in action the full selected aperture of the lens is acting upon the part of the plate exposed.

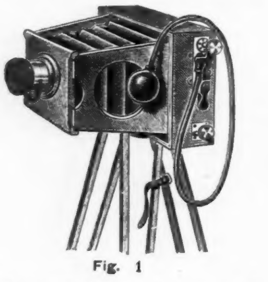


Fig. 1

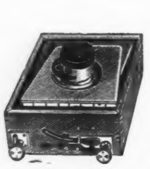

Fig. 2

Among the specimens of apparatus described at the meeting was a new hand camera designed by Major Lysaght, over which much care and thought had evidently been expended, and Mr. T. Samuels, another amateur, who has spent much time in devising simplifications of photographic apparatus, exhibited a new changing back for cameras, fitted with new holders for films, and which grasped them at all four sides.

Mr. Dallmeyer and Mr. Shew are also among those who are exhibiting specimens of their photographic apparatus at the Aquarium, where, among other things, the former exhibitor has on view a photographic telescope, equatorially mounted, and with driving clock complete. The Platinotype Company also is demonstrating there its beautiful process for producing permanent photographic prints in platinum black; it also has on view a new modification of its simple and effective "key" hand camera, adapted to the purpose of taking stereoscopic negatives.

## ENGINEERING LABORATORY INSTRUMENTS AND THEIR CALIBRATION.*

By Professor D. S. Capper, M.A., A.M.I.C.E.

The extent to which laboratory experiments can be relied upon evidently depends upon the accuracy of the instruments employed. The careful calibration of measuring instruments against a uniform standard is therefore of great importance where anything beyond a rough approximation is required.

In experiments on strength of materials, considerable divergence in the results obtained by different observers is due to this cause. In such experiments, both machine and strain-measuring instruments require calibration. A 100-ton vertical machine of the Buckton type, with a jockey weight of one ton, is reliable, and about 20 lb. absolute load if in good order. But errors in placing and reading the position of the jockey weight may amount to 45 lb. absolute load, and specimens to be tested should therefore be of such a sectional area that the resulting error is negligible. In ordinary specification tests it is generally sufficient if the elastic limit and breaking load are known to 1 per cent., but where modulus or resilience is required, a greater accuracy will be necessary. To be certain of the second figure of the modulus, a 10in. steel or iron test bar on the above machine would require to be at least $\frac{3}{4}$in. in diameter. A bronze or gun-metal bar must be of still larger section.

Extensometers to maintain the same reliability must measure accurately to the ten thousandth of an inch. A horizontal machine of the Kirkaldy type, where the jockey weight is adjustable, is suitable for specimens of smaller diameter, the limit being the accuracy of the machine itself. The machine in the author's laboratory at King's College is of this type, and a recent calibration of it against dead loads showed that it could be relied on to less than 20 lb. absolute load.

Another class of experiments which touch commercial work even more closely are engine experiments. The need for calibrating indicator springs and steam gauges is perhaps not always realised. It is impossible to make and keep these instruments reliable under the very trying conditions under which they are used, and where accuracy of power measurement is of importance a direct calibration of the indicator errors against some standard, such as a column of mercury, is indispensable. The author has recently erected such a column for testing indicators and gauges under steam up to 170 lb. pressure in his laboratory, and finds that the best indicators of the parallel lever kind are liable to errors, which reach 10 per cent. values when the indicator is taken over a 2in. pencil range. By plotting the errors at a number of consecutive pressures, it is easy to determine the range beyond which any individual indicator and spring should not be used.

The errors obtained generally fall for a considerable portion of the range reasonably well along a straight line, and from this line the true scale of the spring can be determined. The point which marks any considerable increase in these errors is the point beyond which the spring should never be used. The correction line may be either above or below the nominal scale line of the spring, and may thus either tend to increase or diminish the area of the resulting indicator diagram. Where the deviation from the true scale is found to be small it may be neglected, and the limits within which the indicator readings are true will then be known. Where indicators show much tendency to "backlash," the question of correction becomes much more complex. Two curves will then have to be plotted, one for falling and the other for rising pressures, and separately applied to the rising and falling lines of the diagram. This is a process which is of course out of the question in many cases; and the great object will then be to avoid the use of indicators which show a marked tendency in this direction.

A form of indicator which promises a considerable amount of freedom from backlash has recently been introduced into this country. It is of the rotary form, and is devoid of multiplying and parallel levers of any kind. Very good results, as far as backlash is concerned, have been obtained with this instrument.

## THE INSTITUTION OF CIVIL ENGINEERS.

### SUBJECTS FOR PAPERS—SESSION 1894—95.

The Council of the Institution of Civil Engineers invites original communications on the subjects included in the following list, as well as on any other questions of professional interest. This list is to be taken merely as suggestive, and not in any sense as exhaustive. For approved papers the Council has the power to award premiums, arising out of special funds bequeathed for the purpose:—

1. The Thermodynamic Problems involved in the Production of Power and of Heat without Smoke.
2. The Utilisation of Heat (*a*) generated in the compression of air and other gases; (*b*) carried away by steam engine condenser water; (*c*) contained in boiler furnace flue gases.
3. The Measurement of the Condition of Steam as to Dryness.
4. The Production and use of Superheated Steam.
5. The Comparative Efficiency, as shown by independent testing, of different types of (*a*) stationary engines; (*b*) marine engines; (*c*) locomotives; and (*d*) workshop motors.
6. The different Methods of Governing Steam Engines, so as to give Uniform Speed with greatly varying Loads.
7. The Arrangements of Boilers and Engines best adapted for Electric Light Stations under different conditions.
8. The Machinery of Modern Warships.
9. The Lubricants in use for the Machinery of Steamships, the methods of lubrication employed, and the recovery of waste oil in the engine-room.
10. The Stresses in the Crank and Screw Shafts of Marine Engines.
11. Steam Locomotion for Passenger Traffic on Common Roads.
12. The Application of Oil and Gas Engines to tractive purposes on tramways and on common roads, and to marine propulsion.
13. The losses that occur in Gas Engines and means for reducing them, with special reference to "after-burning."
14. The relative merits of the several Cycles in Gas Engines.
15. The Theory and Development of the Compound Steam Turbine.
16. Mountain Railways: their laying-out, construction, and working by cables, rack engines, &c.
17. The laying out and arrangement of Railway Stations.
18. The Design and Construction of Railway Carriages having reference to (*a*) lavatory accommodation; (*b*) provision for refreshments; and (*c*) sleeping arrangements.
19. The Encroachments of and Reclamation of Land from the Sea.
20. The Buoying and Lighting of Tidal Rivers and Estuaries.
21. Investigations as to the quantity of Water yielded by the Chalk Formation.
22. The Purification of Sewage by Filtration, Precipitation, Electrolysis and otherwise.
23. The Means and Appliances, other than sewers, for dealing with the Refuse of Towns.
24. Plant for the Treatment and Disposal of Waste Effluents from Manufactories.
25. The Working of Inclined Retorts in Gasworks.
26. The Design and Construction of Modern Gasholders of large size.
27. The Methods of Enriching Gas for illuminating purposes and their relative advantages.
28. The Theory and Practical Working of Single and Multiphase Alternate-Current Motors, illustrated by examples of existing installations.
29. Alternate *versus* Continuous Electric Currents for (*a*) Electric Lighting; and (*b*) Transmission of Power.
30. The Forms of Electrical Conductors for lighting, stationary power, heating, and tractive purposes.
31. The Utilisation of Electric Lighting Plant during hours of small demand.
32. Electric Lighting and Haulage Plant in Mines and Collieries.
33. The Application of Water Power, and its transmission to a distance by electricity.
34. Electrical Motors for (*a*) Inland Navigation and (*b*) Ocean Vessels.
35. The Use of Electrical Motors for driving machine tools in engineering workshops.
36. The Design of Navigable Balloons and of their propelling machinery.
37. Quarrying Operations and the Plant employed.
38. Coal-winning in seams situated at great depths below the surface.
39. Explosions from Coal-dust in Mines.
40. The Surface arrangements of Collieries; including those for banking, cleaning, sorting, and screening the coal.
41. Coal-shipping Appliances and Discharging Apparatus.
42. The Comparative Merits of Blast or Reverberatory Furnaces.
43. The Manufacture and Application of Steel for Structural purposes.
44. Standard Designs for Main Girders and Floors of Railway Bridges of Steel.
45. The Present Position of the Basic Steel Process.
46. The Molecular Constitution of Iron and Steel.
47. The Micro-structure of Iron and Steel.
48. The most suitable Alloy for the working parts of Pumps for lifting acid-waters from mines, &c.
49. The Treatment of Tin and its associated Ores.
50. The Effect of small quantities of Impurities in Commercial Copper as regards its use in Electrical work.
51. The Electrolytic Deposition of Copper.
52. The Uses of the Rarer Metals, and the modes of extracting them from their combinations.
53. Aluminium, its manufacture, properties, uses and alloys.
54. The arrangement of Engineering Workshops, with descriptions of modern Machine-Tools and Appliances.
55. The present Limits of Speed at Sea.
56. The most recent types of (*a*) Passenger and Mail Steamers; (*b*) Cargo Steamers; and (*c*) War Ships.
57. On Fast Cruisers, Torpedo Catchers, &c.
58. The Loading and Discharging of Grain Cargoes.
59. The recent developments of Mechanical Refrigeration, and auxiliary Plant employed therewith.
60. The Screw Propeller of the present day, its material, proportions and efficiency, and the Relative Advantages of Single Screws and of Twin Screws in Vessels of High Power.
61. The Comparative Merits of the various modes for Manufacturing and Gauging Ammunition with solid-drawn Cases.
62. The Manufacture of Heavy Ordnance.
63. The Manufacture of Armour.
64. The Organisation and Execution of any Railway or other Work, with reference to the cost of materials, labour, and plant.

## CATALOGUES.

Loewe and Co., Ludw., Berlin. London: H. F. L. Orcutt. Oil Testing Machine. Hammers and Heating Forges. Air and Gas Fans and Furnaces.

Vosper and Co., London and Portsmouth. Oil Engines and Oil Launches Complete. A catalogue which affords some proof of the position now taken by these engines without boilers and of the increasing sizes of launches propelled by them.

Easton and Bessemer, Limited, Taunton. Engines, Boilers, Woodworking, and Grinding Machinery, Pumps, Edge Runners, Pan Mills for Sand and Coal Dust Grinding, Mortar Mills. A well-prepared catalogue illustrated with good engravings.

Herbert, Limited, Alfred, Coventry. Horizontal Milling Machines, Vertical Milling Machine, Universal Cutter-Grinder, Sensitive Drills, Capstan Lathes for repetition and general work, Universal Grinding Machine, Special Machinery for Cycle Manufacture. A catalogue in sections with good illustrations of new machinery.

H. Bamford and Sons, Uttoxeter. Bamford's "Rapid" Grinding and Crushing Mills and Split Pulley.

Joseph Cook and Sons, Washington Ironworks, County Durham. Illustrations of their leading manufactures, including everything used in or about collieries or mines, such as pulley frames, pit gear, iron, steel, and wood tubs, trucks and wagons, engines, iron and steel cages for from two to six tubs, foundry ladles and sinking kibbles, rollers, drums, and sheaves, winding pulleys, pit heapsteads and cleaning arrangements, with picking belts and shaking screens, teaming cradles, coal washers. A costly catalogue of useful size—8vo—full of illustrations, but no name on back.

A Coalowner's Proposal for Settling Coal Values.—Speaking at the annual meeting of the shareholders of the Sheepbridge Coal and Iron Company, at Sheffield on Tuesday, Mr. C. B. Maclaren, M.P., one of the directors, and a large holder in colliery undertakings in South Yorkshire and Derbyshire, made a suggestion which has caused no little comment in the district. It was to the effect that coalowners should work together more harmoniously than they had done in the past, and ought also to co operate with the Miners' Federation in endeavouring to settle and steady prices. The men had a very powerful organisation, and he had not a word to say against it, for he had always contended that a strong Miners' Federation was the best guarantee for good trade, if the masters knew how to take advantage of it. The coalowners, he thought, ought to work with the Federation, and recognise the power the men possessed, instead of trying to undersell each other to gain a paltry advantage over their rivals. Coalowners should aim at steadying prices together, and in concert, if necessary, with the leaders of the Miners' Federation, on a basis which would be remunerative to all parties. He contended that this could be done perfectly well. It was not a question of shillings, but often only a question of pence. These pence, however, meant a matter of pounds. He deprecated any idea of exacting unfair prices from the public. All that was asked was that whilst the men took a fair living wage, the shareholders should at the same time have a fair return on their capital. "That return," said Mr. McLaren, "is not to be obtained by owners slipping out of a meeting by a back door, and wiring acceptances of railway contracts at 6d. less per ton than the price agreed upon at the meeting." That sort of thing, he said, had been done at meetings of owners in the Midlands, and he held that it was not the right state of things, and while it lasted the men might justly complain that the owners did not assist them to keep up prices.

* Abstract of paper read before Section G of the British Association at Oxford.

## LETTERS TO THE EDITOR.

*(We do not hold ourselves responsible for the opinions of our correspondents.)*

### TRADES UNION POLICY.

SIR,—The events of the Scotch strike have been extremely suggestive. They have been the outward palpable manifestations of a tendency which usually brings about deplorable results. As such, they are extremely instructive.

The mixed multitude of men working in Scotch mines is largely composed of Irishmen. There are also North-country Englishmen, Welshmen, men from Devon and Somerset. Of true bred Scotchmen there are comparatively few, because Scotchmen do not as a rule take kindly to mining. It is, I think, a time for speaking out and stating the plain truth. In the Scotch, as in all other mines, will be found a percentage of shrewd, competent men who are skilled in their business. They are miners in the proper sense of the term. The remainder are mostly farm hands, and what may be termed "drift." The pay that a miner can earn is always greater than that of a field labourer. The moment the pit has been opened in any district the field hands crowd to it for employment. The facts are quite well known. They have been stated over and over again by such authorities as Mr. Pickard. There is not at this moment the slightest difficulty in getting all the hands needed to work the mines, if those who are heart and soul for the strike would quietly withdraw and leave the contented hands and the new men who would come forward to themselves.

Now, any individual who studied the signs of the times must have known that a strike could not possibly succeed. The only chance lay in the power of the colliery proprietors to drive up prices; but this could not possibly be done while the iron and other trades were so bad. It is not too much to expect the colliers to know such things in a general way; and it is certain that the union leaders, whose ostensible business it is to look after the interests of the men, ought to have possessed the most minute information on the subject. In the present day the intelligence department of an army is regarded as of the utmost importance. A strike is an open declaration of war. If the intelligence department of the Union did its business properly, a blunder such as the Scotch strike has been would have been impossible. The patent fact is, that of late years the leaders of the Unions have been deteriorating—and that rapidly—in common sense. Instead of being, as they ought to be, hard-headed sensible business men, they are simply and only blatant wind-bags, who are manifestly incapable of guiding their men to victory. I have heard it said that Mr. Keir Hardie is an enthusiast, and is not to be judged by the same standard as other men. But let us fancy what would take place if a general commanding an army was an enthusiast and nothing else. Trades Unionism is right; it has done much good, it is capable of very considerable things—but its affairs must be managed by competent business men, not by hot-headed dreamers.

It is not enough, however, merely to state a case, we must go on to consider the cause. Why is it that such men as typical Keir Hardie get into the positions that they hold? Now, on examination, I think it will be found that they are one and all great talkers. In all ages mankind has been led by the talkers. But the men who do the world's work are not the talkers after all. If, however, Mr. Keir Hardie and his fellows had to rest content with addressing here and there a few hundred miners they would quickly give up the functions of the orator, and turn to something else. Such men have been rendered possible only by the newspaper press. It is impossible to overrate the vanity of the class, and nothing on earth so flatters and pleases that vanity as the publicity which is afforded by the Press. It would be too much to expect reporters and editors to leave the Union leaders and their utterances severely alone, although the best results would follow from the adoption of such a course. But failing this, it seems to me that the Press, having the interests of the workers at heart, should do that which I am doing, and urge on Unionists throughout the length and breadth of the country the vital necessity of selecting to lead them men who are really competent, from a business point of view, to do the work.

The strike in Scotland has failed. It has inflicted frightful misery on multitudes. It was all brought about by a handful of Union leaders. Now, what excuse have these men to offer for the mischief they have wrought? I will not adopt the monstrous theory that the English Federation selfishly brought the strike about in order that English miners might benefit by the ruin of Scotchmen. But we are in any case face to face with the fact that a fearful blunder has been committed. If we assume that the leaders were confident of success, then it is clear that they were ignorant of facts with which they ought to have been perfectly familiar. The strike was a blunder. If, however, they knew that the chances were a hundred to one against its success, then it was a crime. To me and to, I think, most sensible men it has been nothing more nor less than the result of an overweening self-confidence, backed up and urged on by that senseless antagonism to capital which is an embodiment of one of the heights of human folly. The "working man" would not trust an idiot to spend his wages for him. When will he learn that those whom he trusts to lead him ought to be men possessed of common sense?

As the strike has failed we hear a cry for the nationalisation of the coal mines. When that takes place, and the State becomes the owner, the Union leader will be no more. There will be no place for him in the scheme, and "the State" will make very short work of the matter. The moment coal becomes plentiful in excess of the demand at the price fixed by the State, the pits will be shut and the miners sent about their business. That is what the Government is now doing at Woolwich, discharging men because they are not wanted. If the State fixes a price which no one will pay for coal, there will be an end to the demand for it. So with iron, so with every other commodity. It would not do, however, for a Union leader to make this statement. If he did he would cease to be a leader; his salary would no longer be paid; but that is only because so many workers are so unutterably ignorant of what goes on in the world around them.

There is one bright spot in the whole matter. It is that the Union leaders will discredit themselves by their folly. Already Mr. Keir Hardie has ceased to be a power. There is in every Union a considerable minority of hard-headed, sensible men. There is some evidence that they begin to think it is time that their voices were heard. If they would but combine and exert themselves there would be a chance for labour. Unless the millions of working men in this country refuse once for all to be led by men who are so incapable and so ignorant that they brought about the Scotch strike, the end must be disaster. The one thing of all others most wanted at the present time by the working man is not more wages, or shorter hours, or a higher education, but common sense.

GRETA BRIDGE.

Dunfermline, September 24th.

### THE SCOTCH STRIKE AND THE SCOTCH PRESS.

SIR, I wish your excellent article on the coal strike could be read by the blockheads concerned in it, or even by the newspaper men in the district. As for the *Mail*, any man who by reason of his qualities gets his head above his fellows, is a fair mark for its slings and arrows. Nobody pays much attention to the *Mail* for all its desperate attempts to attract notice.

The whole disturbance would have been over long ago but for the fact that the Scotch papers, even the respectable ones, have devoted whole sheets to the chronicling of the sayings and doings of Mr. Tom at Camlachie, Mr. Dick at Auchengray, and Mr. Harry at Cowdenheath. The ridiculous vanity of these "leaders" has been pampered to the uttermost. Their gabble appears in the evening papers and re-appears in the morning issues. Even the usually sober *Glasgow Herald* has its shrieking headlines to draw attention to the drivel with which its columns are filled. The characteristic interruptions of the Irishry, "To h—l with the coal-masters," and the like, are all duly inserted along with the scarcely less violent utterances of the man on the cart.

It is said, I know not with what reason, that these pests are even *paid* by the newspapers to furnish copy; the effect of this on the duration of the strike may be imagined.

The collapse of the Scotch railway strike dates from the time when the orators on that occasion offended the too sensitive reporters, who retaliated by letting these same orators severely alone. The strike endured every form of adversity except indifference. Mr. John Burns retired to London in disgust when his bellowing attracted no attention beyond the limited circle of his hearers, and the still small voice of common sense began to have a chance.

When the present rabble of agitators is ignored altogether by the Scotch press, the strike will die a natural death.

Glasgow, September 22nd. OLD GLASGOW.

### LABOUR AND LUXURIES.

SIR,—In the report of a meeting held by some of the Woolwich workmen it is stated that one of them made use of words which are worth notice and correction because they are the embodiment of a popular fallacy. The men grumble because many are being discharged by the Government. The man in question said that the wages were "only 19s. 6d. a week, about the cost of a bouquet worn by one of the Government clerks."

The assumption is that the money thus spent—supposing the statement to be true—was wasted. This is a fallacy. Those who are wealthy are blamed for spending money on horses, carriages, and so-called luxuries. It is easy to see that from the political economical standpoint they are not at all blameworthy. Let us stick to the bouquet. The flowers must have been grown under glass, and in their production they gave employment to the bricklayer, the carpenter, the glazier and painter, the ironmonger, the founder, the paint maker. The price of the flowers was divided among all those and the landlord of the garden, the hot-water engineer, the gas company who supplied the coke, the gardener, flowerpot maker, and the maker of artificial manure. Then another portion went to Covent Garden or other florists, and to the girl who made up the bouquet and the wire-drawer who supplied the wire. It would perhaps not be easy to select a worse example of mis-spent money than was this; almost the whole sum was divided among working folk.

If the critic whose words I have quoted had his way, the same sum would have been diverted into a different channel; that is all. The result of the expenditure would have been, say, 19s. 6d. worth of cartridges; of the two it seems to me the flowers are the more innocent. Precisely the same line of argument as that I have employed applies to carriages, rich carpets, &c. In all cases these represent the expenditure of money among a very large number of workers. It may be urged that the result obtained might be better, but this has nothing to do with those who produce. The best possible result for them is money, and that they obtain whether the thing produced is useful, destructive, or ornamental.

The principle involved in my argument has always been held sound by the best authorities. It is a pity it is not better known.

London, September 25th. Y. X.

### THE VELVO BATTERY.

SIR,—We thank you very much for your very full article in your last issue describing our batteries.

Regarding the smell your representative observed on the Velvoca, it was due to the newness of the ebonite cells, and has already nearly disappeared. For some time now there has been no smell from the smaller boat Velvo, and the odour was far stronger during the first few trips than anything we have had on the Velvoca, which, by the way, I think can hardly be called a small electric launch; there are few electric launches on the river of more than 35ft. in length and 6ft. 6in. beam.

Regarding the cost of current, half speed, which costs only 1s. 8d. an hour, is nearly as fast as full speed, and is a perfectly satisfactory rate of progress for the river. The boat will carry a dozen persons comfortably, and the cost of under 2d. an hour per person carried cannot be considered excessive.

In connection with lighting work, there are very few cases in which the cost of current from my batteries would amount to more than 2s. per B.T.U., and in very many cases the cost would not exceed 1s. 6d. I know many small installations fitted up in the ordinary way where the first costs have been far higher than a battery plant would have entailed, and where the working expenses run up to and exceed 2s. per B.T.U.

I claim that one of my ½-kilowatt batteries would not need more than half an hour's attention per recharge in a period averaging three weeks.

I may mention that I will not in the future allow the boat-builder to make the battery box, but shall have it properly dovetailed and provided with a close-fitting lid, a pipe running to the stern of the boat carrying off all hydrogen generated.

For THE BATTERY AND MOTOR CO.
(H. T. BARNETT, Manager.)

### TRACTION ENGINES.

SIR,—I wonder none of your correspondents have called attention to the red tape wrapped round and round traction engines; upon an average, I believe, England contains one traction engine to every three miles of turnpike road. The cost of traction engine haulage may be taken at twopence per ton per mile, and ordinary cartage at one shilling. In the light of recent legislation, the lowest maximum haulage rate Parliament would be likely to sanction upon "light railways" would certainly be at least twopence per ton per mile. But borough and county bye-laws, *i.e.*, red tape, throttle traction engine traffic by differing to an absurd degree; for example, in counties adjoining, a traction engine may travel by night in the one, and in the next an engine must not move after sunset; whilst a borough may insist upon the deposit of £100 being made before a wheel is turned in it. Some of the bye-laws are fifteen to twenty years old, and others, with all the force of law, are out of print.

The statutory right to shut up the roads for eight hours is made use of by some local boards to stop this traffic. Others, again, bar their roads to traction engines by public notice upon their bridges that they will not carry them, though these bridges do. As if this was not enough, every traction engine has to have a separate £10 licence for each county. Now, Sir, if our rulers would only put their heads together and make these bye-laws uniform to the whole kingdom as well as the licence, do you not think a good deal of traffic would result of advantage to the farmer, the railways, and the people too? With bicycles and tramways upon our coach roads, what possible harm can a traction engine do that it cannot be made to pay for?

ROBERT CAPPER.

18, Parliament-street, Westminster, S.W., September 25th.

### THE SAMUEL MORLEY MEMORIAL COLLEGE.

SIR,—May I call attention to the evening classes for working men and women held here? A new session begins October 1st. Fees, from 1s. 6d. a term for the first class, and 6d. for a second-class if more than one is taken. Special lectures 1s. the course to College members, 1s. 6d. to outsiders. The subjects taught are very various. Languages, grammar, part singing, violin, dress-making, cooking, book-keeping, and shorthand are only a few of them. Some, such as mechanics, building construction, hygiene, &c., are in connection with South Kensington. But at this time three courses are about to begin, especially worthy of attention. One is a university extension course on Thursdays, by P. H. Wicksteed M.A., on the "Life and Structure of Human Society," a subject of special interest at a time when social questions are so much to the fore. Another is on "Early Tuscan Art," by Miss Taylor. The third, on Fridays, is by Professor Pritchard, M.R.C.V.S. on the "Care of Horses." A similar course last winter was attended by 130 men, chiefly drivers and stablemen, all practically interested in horses, and taking full advantage of the opportunity given them to ask questions.

Physical training both for men and women is provided by means of a gymnasium. For recreation there are cricket, football, and other clubs, while social evenings once a month offer an opportunity of friendly intercourse such as working people in their crowded homes find unusually difficult of attainment.

Full particulars may be had any evening at the College, or by letter to the Principal.

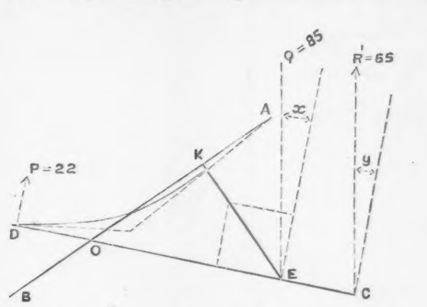
C. A. MARTINEAU,
(Principal.)

Waterloo Bridge-road.
September 26th.

### THE GRAPHIC STATICS OF A DECK CHAIR.

SIR,—I regret to have to ask you to correct an oversight made by me in my last communication on this subject. In computing the tension in O E, I forgot to add to it the difference between the components $x$ and $y$ parallel to O C.

The better way of making this computation would be to find the perpendicular force at E, resolve it along E K and E O, and from the tension obtained in E O, if it be under tension, subtract the component $y$, or the compression along E C.



The tension, therefore, in E O of my former diagram would have to be increased from 35 to, say, 38 or 39. It would perhaps be difficult to bring out the same figures as I gave in my last, as a very slight alteration of the angles makes a considerable difference, and my own measurements were only approximately close.

16, Nelson-road, Southsea, C. L. S.
September 24th.

### THE THEORY OF THE STEAM ENGINE.

SIR,—Mr. Maurice Cross's letter in your issue of the 21st inst. is not to the point. I have not read, and do not intend to read, the correspondence which has appeared in your columns *re* steam engine efficiency, but I did read Mr. Cross's letter on "The Theory of the Steam Engine," and formed the opinion that, as I have already stated, it was either obscurely worded or absolutely erroneous. That opinion I have seen no reason to change; his last letter simply strengthens it. I have introduced no irrelevant matter into the consideration of the point, which, so far as I could comprehend, he was endeavouring to support, viz., that steam and air behaved in an intrinsically different manner when expanded without doing work.

I have not leisure at present to pursue this correspondence very far. I will simply observe that the increase of energy of a pound of air when expanded without doing external work or reduction of temperature is not, as Mr. Cross appears to assert, properly to be termed "infinitesimal." Its amount is calculable, and, although small when compared with the total amount of energy of the fluid, is quite appreciable, and certainly in no proper sense of the word is it "infinitesimal."

Also Mr. Cross appears to imply that Rankine was without experimental verification of the "probable" superheating of saturated steam after free expansion. If my memory serve me correctly, Mr. Cross is in error here, and that experiments have demonstrated the fact of the superheating.

The reason for my reference to air at its critical point appears not to have been understood by Mr. Cross. I should have thought, however, that it was sufficiently clear.

HENRY CHERRY.

21, Festing-road, Putney, S.W., September 26th.

### BELLEVILLE BOILERS.

SIR,—We observe in your impression of the 14th inst., under the heading of "Decennial Programme for Naval Construction in France," mention is made that the vessels Charlemagne and Catinat are to be fitted with Belleville boilers. We beg to draw your attention to the fact that other ships mentioned in your interesting article, viz., Bouvet, Descartes, Pothuan, Pascal, Galilée, and Lavoisier are also to be supplied with boilers of the Belleville type.

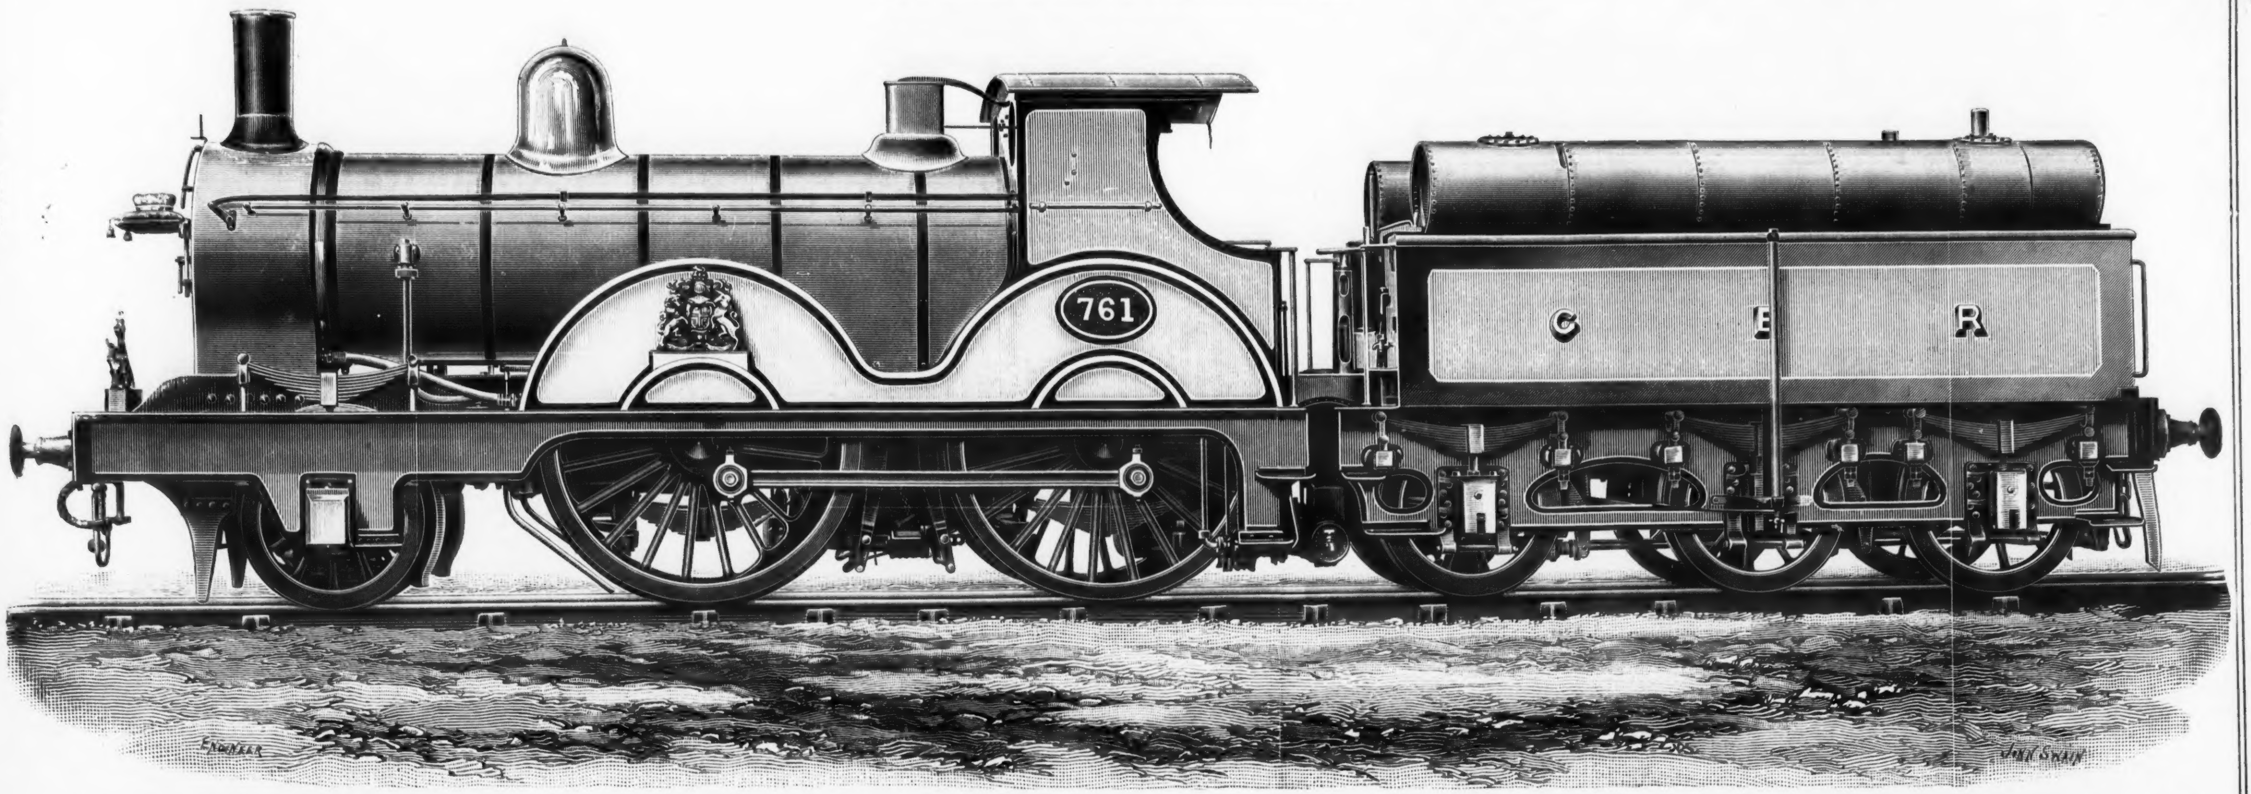
For MAUDSLAY, SONS, and FIELD, LIMITED.
(JOHN SAMPSON, Director).

Lambeth, September 25th.

**PETERHEAD HARBOUR WORKS.**—According to a report on the above for the years 1893-4 by Messrs. Coode, Son, and Matthews, the engineers-in-chief, recently issued as a parliamentary paper, progress is being continued both with the Barge Harbour and South Breakwater. The quarry has been further opened out by the removal of about 5400 cubic yards of boring and decomposed rock. The railway, dockyard, &c., have been properly maintained, and additional plant, comprising steam cranes, travellers, trollies, driving gear, &c., has been provided. In the Barge Harbour there was excavated from its bed to form the new basin 2012 cubic yards of rock, of which 945 cubic yards was below low-water level. The staging in the harbour was extended about 200 lineal yards, and the necessary approaches made thereto. A length of 150ft. of the sea wall was built and blocked with rubble, involving the use of rubble backing, 1865 cubic yards; concrete blockwork, 1301 cubic yards; concrete tugwork, 58 cubic yards; concrete masswork, 556 cubic yards; granite ashlar in facework, 5124 cubic feet. The whole of the blocks required both for the quay and sea walls are made. The South Breakwater has extended 105ft., the foundations of a further length of about 40ft. prepared, and the work thereon brought up partly to the level of 4ft. below, and partly to that of 2½ft. above low water. The foundation work has during the previous year involved much rock excavation and levelling under water by divers. The chief items of work carried out were: Rock removed by divers, 173 cubic yards; concrete blockwork deposited, 3182 cubic yards; concrete tugwork deposited, 584 cubic yards; concrete masswork, 1386 cubic yards; granite pitching, 2525 super. feet; granite ashlar, including facework, 9407 cubic feet; permanent way laid, 60 lineal yards; gas and water pipes, 40 lineal yards. Blocks containing 1261 cubic yards of concrete and 4893 cubic feet of ashlar were made, but not set. The daily average number of men employed during the year was 362, of whom 229 were convicts.

# EXPRESS LOCOMOTIVE, BURNING OIL FUEL, GREAT EASTERN RAILWAY

MR. J. HOLDEN, M. INST. C.E., STRATFORD, ENGINEER



## THE OIL-BURNING LOCOMOTIVE PETROLIA.

In former articles we have described the ingenious arrangements for burning liquid fuel invented by Mr. James Holden, Locomotive Superintendent, Great Eastern Railway. Recently we have spoken of the express engine No. 761, the Petrolia, and we now illustrate that locomotive and the oil-burning arrangements above and on page 277. One of the most recent modifications introduced by Mr. Holden deserves special notice. Although the Westinghouse brake is used by the Great Eastern Company, the Great Eastern engines have frequently to haul mixed stock of other companies fitted with the vacuum brake. It is known that a small ejector has to be kept constantly at work maintaining the vacuum, and the steam used for this purpose represents an expenditure of fuel amounting, it is said, to about one pound of coal per train mile; whether it is less or more, however, is of little consequence. The loss is appreciable. Mr. Holden, to save it, uses the inducing steam blast blowing the liquid fuel into the furnace. The air from the train pipes is, in other words, forced into the fire.

The driving wheels of the engine are 7ft. diameter, the leading wheels 4ft. diameter, and the cylinders 18in. by 24in., cast in one piece, with the valves underneath. The link motion is of the Stephenson type. In this boiler there are 256 steel tubes $1\frac{5}{8}$in. diameter. The shell is of steel plates $\frac{1}{2}$in. thick, the fire-box of copper, the heating surface 1230 square feet, the grate area 17·9 square feet. The total weight of the engine in running order is 42 tons, and that of the tender in running order is 32 tons. The liquid fuel burning apparatus is placed below the footboard, so as not to interfere with the ordinary working of the locomotive. Further, the fire-bars, &c., remain, and are available for coal firing, either for lighting up and raising steam, or for ordinary coal burning, should it by accident or design become necessary. The injectors — described later — face two holes provided through the fire-box casing, about 12in. above the fire-bar level.

The usual practice on the Great Eastern Railway is to keep the fire-bars covered with an incandescent base of solid fuel, limiting the combustion by partially closing the damper; the air necessary for the oil fire is introduced by the action of the ring blower of the injector above the solid fuel base, and as the spraying and distribution are also effected by the steam jets, no exceptional firebrick is required.

For fuel, oil, and coal gas tars, creosote oils and petroleum residues are used. With any of these, if fair samples, one ton will replace nearly two tons of coal. This difference in favour of the oil fuel is not only to be attributed to the higher calorific value of it, but also to the fact that very complete combustion can be secured, and no unnecessary air need be admitted at the fire door, as usually occurs at intervals of firing with a coal fire. In addition, the fire can be exactly regulated to meet requirements.

The liquid fuel is carried in two cylindrical tanks on the tender, with a combined capacity of 600 gallons. From these it is conveyed by pipes and a flexible connection to the engine. Here branch pipes are provided to each burner with regulating valves working through spindles from a convenient position. This regulating gear is shown separately to a large scale on page 277. Liquid fuel can be simultaneously admitted or shut off at both injectors by one horizontal movement of the handle marked A, or the fuel can be regulated and controlled to either one of the injectors by turning the milled heads B′, B″. These lift the valves C′, C″, whereas the partial turn given by the handle A merely revolves the valves like the plug of a cock. On reaching the injector the fuel is sprayed by an internal annular steam jet. This steam, as it escapes from its orifice to receive the fuel, sets up a strong induced current through a central air tube; this eduction of air is utilised for securing the continuous vacuum for the automatic vacuum brake—22in. vacuum—or by means of a cock marked L. The vacuum pipes can be put into communication with air heating coils in the smoke-box, thus supplying hot air to the centres of the injectors for combustion. The fuel spray escaping from the nozzle of the injector is further atomised by the small jets of steam arranged around the ring of the burner, at the same time the ring acts as a blower, inducing atmospheric air for complete combustion, and further it spreads and diffuses the flame and heated gases over the fire-box. Steam is obtained from a fitting on the fire-box front, having an internal pipe to the dome. Four cocks are shown, one for steam to the central jets of the injector, one for the ring blower on the same, one for steam to the warming coils in the oil tanks, and one for allowing a steam jet to enter the oil pipes for cleaning purposes.

In consumption of fuels, the liquid fuel burners for a month's average of over 3000 miles burn:—Coal for lighting up, standing, &c., 11·8 lb. per mile; liquid fuel, running, 10·5 lb. per mile; total, 22·3 lb. per mile. This compares favourably with a consumption of 34 lb. per mile of coal on similar engines on same service. On June 15th, 1894, engine No. 761 ran through from London—St. Pancras—to Scarborough and back, with a special train of saloons, dining car, &c., weighing 200 tons. The total distance is 534 miles, and consumption of fuel 11·5 lb. of coal per mile and 11·25 lb. of liquid fuel per mile; total, 22·8 lb. per mile. The fire was not cleaned, and the only stoppages made were those required for water and oiling the engine.

## ELECTRICITY IN THE TURRET.

Keeping pace with modern progress, the Ordnance Department of the Navy has about determined to operate the guns and turrets of the men-of-war belonging to the United States Navy by means of electricity in future. It is not intended that electricity shall entirely take the place of steam for this work, for there will be no attempt to replace the existing method with the new one. The new system will, however, probably be placed on board many of the ships, where it will take the place of the steam apparatus should the latter be injured in any way. In any event it has all but been decided to equip the battleship Iowa and the new cruiser Brooklyn with this system when they are sufficiently advanced towards completion to receive it.

Experiments of a most severe character have been going on with the system for some time past. In order to thoroughly test its capabilities, Capt. Sampson, Chief of the Bureau of Ordnance and Ensign Joseph Strauss, who has special charge of all matters relating to turrets, visited League Island on Wednesday, where they witnessed a severe test of the system, and, in fact, operated it themselves. Electric turning gear has been installed in the turrets of the old monitor Montauk, which is lying at the Navy Yard at League Island. Before the arrival of these officers it had been given a thorough trial and worked admirably. Captain Sampson and Ensign Strauss carefully examined the apparatus and found that it not only worked perfectly, but that it was decidedly better than the steam system now in vogue.

It will be remembered that the Department intended fitting the turrets of the cruiser New York with an electric system, but for some reason or other steam was adopted instead. There are numerous advantages which electricity possesses over steam, and it is because of this fact that the ordnance officials have been anxious to secure some system by which it could satisfactorily be used to operate the guns and turrets of the big vessels. With the new system there would be an absence of the steam pipes which the vessels are now supplied with. The electric wires could be easily run around bulkheads, instead of boring through them, as the workmen are now compelled to do in the case of pipes conducting the steam for the turning gear of the turrets. Should they become injured in battle, there would be no way by which the turrets could be operated and the guns elevated or depressed except by hand power. With an electric wire, a projectile has a smaller surface to strike, and the two ends of the wire could be bound together in an instant and a current re-established without delay were it to be broken.

To the minds of ordnance officials the crowning advantage of the new system lies in the ease with which it is handled. Instead of the valves present in the steam system there is a single lever, which, if thrown to the right or left, turns the turrets with it, or if thrown up or down elevates or depresses the guns accordingly. This lever connects with a small switch, which alters the voltage of the current to the motors. The current by which the system is operated may be obtained from the electric lighting machinery of the vessel, a current of 80 volts being all that is necessary to work it. *U. S. Army and Navy Journal.*

"THE ENGINEER" SWAIN ENG

## RAILWAY MATTERS.

It is officially announced from Delagoa Bay that an agreement has been arrived at between the Netherlands Railway Company and the Portuguese Government, in accordance with which a reduction of 12s. per ton will be made for the railway carriage of goods landed at Delagoa Bay ex direct steamers. The agreement is for a term of one year, and is subject to ratification at Lisbon.

The Tonawanda Valley Railroad will hereafter be known as the Buffalo, Attica, and Arcade Railroad. An American contemporary says no other road in the State has had so many titles as this road. It was built in 1853 and called the Attica and Arcade Railroad; then its name was changed to the Attica and Alleghany Railroad, and later on, in 1872, it became the Tonawanda Valley Railroad. Afterwards it was known as the Attica and Freedom Railroad, and now its present name. At first it was built as a standard gauge road, and in 1870 it was made narrow gauge. At present it is being altered to the standard gauge.

The following list of proposed Indian railways to be surveyed, according to present plans, during the winter of 1894 and 1895 is given in the *Indian Engineer*:—Bara-Muttra, 150 miles; Wazirabad-Lyallpore location, 200 miles; Rohri-Kotri location, 206 miles; linking up the metre-gauge systems in Northern India, 90 miles; extensions of the Bengal and North-Western Railway from a point west of the Chota Gunduk to Benares with a branch to Ballia, 157 miles; Hilli-Kaligunge, 48 miles; Northern Bengal-Assam connection—exploration only—200 miles; Arsikere-Mangalore, 125 miles; Shoranur-Cochin, 60 miles; Calicut Cannanore, 55 miles; Tinnevelly-Quilon, 106 miles; Madura-Paumben, 91 miles; Vizianagram-Parvatipore, 300 miles; Chittagong-Minhla, 420 miles; Assam-Burma connection—exploration only; total, 2208 miles.

The second annual convention of the Travelling Engineers' Association was held in Denver, convening on Tuesday, September 11th, and continuing three days. This Association was organised two years ago, for the mutual benefit of the travelling engineers of the country, and "to improve the locomotive engine service of American railroads." The following topics were reported upon and discussed:—True and false economy in caring for and the safe handling of the air brake under all conditions; and when examining a fireman for promotion, how much knowledge of the air brake is it necessary for him to have to be considered fully competent to take a train out on the road? What are the best means of saving coal, and increasing or holding the mileage per ton at a desirable figure? Testing coal in actual service, what are the easiest and most accurate methods? What relation does a clean engine bear to the economical use of oil and supplies? How can travelling engineers improve the service when engines are double-crewed or pooled? On a uniform form of examination for firemen for promotion and new men for employment.

The Bavarian Premier and Minister of Ways and Communications, who has recently returned to Munich from England, Scotland, and Ireland, where he has been spending his vacation, devoted much attention during his visit to the railways of the United Kingdom, of which he speaks in terms of great praise, declaring their traffic arrangements to be excellent and far more developed than in Germany. The Minister was especially struck with the quiet and able manner in which the British railway officials managed to control the enormous amount of traffic which passed through the comparatively small stations, and contrasted their demeanour with that of their colleagues on the Continent, to the disadvantage of the latter. After, however, pointing out the greater speed and smoothness of railway travelling in the United Kingdom as compared with the Continent, the Minister observed that there the advantages of the British system ceased, and proceeded to describe the carriages, the railway stations, and the refreshment rooms as decidedly inferior to the accommodation provided for travellers in Germany.

It is now some two months since it was proposed to adjudicate the concessions for several lines of tramways in the city of Alexandria, and at the appointed date the adjudication was duly announced. Subsequently, however, the Minister for Public Works in Egypt declined to ratify the decision arrived at by the Municipal Council, and the opportunity of re-considering the whole subject *de novo* was taken advantage of, and was unquestionably a step in the right direction. Under the recent fresh arrangement the Municipal Council has invited the assistance and co-operation of the different European tramway companies, who had previously taken great interest in the whole matter, and were fully prepared to do all in their power to further the affair. Unfortunately, the companies retired from the prosecution of the original project, owing to certain clauses in the specification and agreement, which did not coincide with their own particular views. In order to remove this cause of objection, and further smooth away difficulties, the Council, while not losing sight of the interests of the city, will revise these documents, and will shortly announce the date of the next adjudication, which will be as early as circumstances will permit.

It is probable that before the end of this century trains will be running from St. Petersburg through to Vladivostock, on the Sea of Japan. On the eastern division of the Great Siberian Railway trains are running from Vladivostock well into the interior, and it is expected to have the entire line in operation before the end of this year. The western division is also nearing completion. By utilising river navigation, it is found that rails can be laid from three different points at the same time, instead of from but one, as at first supposed; and also that, most unexpectedly, local workmen prove to be very abundant. The Government proposes to spend large sums upon auxiliary enterprises, for the development of the natural resources of Siberia. Branch lines are to be built, the rivers are to be improved, and steam navigation established from points intersected by the railway; colonisation is to be assisted, ironworks are to be encouraged, and scientific expeditions are to be organised for thorough study of the country. For these purposes, along the line of the first division alone 14,000,000 roubles have been appropriated. The total cost of the entire railway is estimated at 350,210,482 roubles. The political and social effects of this stupendous enterprise—which, indeed, is the most gigantic railway undertaking ever planned—will be of tremendous moment.

A recent French railway journal publishes the results of an extensive investigation by M. Couärd, a French engineer, on the life of wood sleepers. He finds that they last much longer under a light than under a heavy traffic. On a line passed by 18,000 trains yearly, the average life was 8·1 years; on a line with 13,000 trains, 9·7 years; and on a line with only 8700 trains per year, the life was 11½ years. He found one local road with only 1760 trains a year, and here the sleepers lasted 18·9 years. The influence of climate may make a difference of one-half in the durability. Further, the number of sleepers per mile has an effect. On a line with 28 per cent. more sleepers per mile than on another, the sleepers lasted 37 per cent. longer. They are worn in proportion to the work they have to do; whence Couärd concluded that heavier rails will make the sleepers last longer. As to grades, he found on double track roads that sleepers on the down track on the average last only 78 per cent. of the life of sleepers on the up track, and that the longest life is on the steepest ascents, which he interprets as meaning that the life of sleepers decreases with the increase of the speed of trains. On some curves the fastening of some chairs—for double-headed rails—are loosened so often that the resetting of them soon destroys the sleepers, the life of which is reduced by one-half in these situations. On other curves he found less effect on the sleepers, yet a reduction of 30 per cent. in their life. Thus he finds the durability of sleepers affected by a great many elements beside the kind of wood and its treatment.

## NOTES AND MEMORANDA.

The deaths registered in thirty-three great towns of England and Wales last week corresponded to an annual rate of 15·7 per 1000 of their aggregate population. This is 1·2 per 1000 more than in London, Halifax had a nominal record for the week, namely, only 6·2 per year per 1000. Liverpool rate was 23·5, and so kept up its reputation which is made for it by its "last end."

It is stated that a Mr. Keyser has soldered aluminium, without the use of any flux at all, by heating the metal and scraping the surface while in contact with a solder, so as to remove the oxidising film until the metal is what is called "tinned." Then union takes place easily enough. The alloy used consists of tin 50, silver 25, aluminium 25, and melts at 750 deg. Almost any tin solder serves, however.

The Glasgow and West of Scotland Technical College Electrical Engineering Laboratory has just received a very handsome addition to its testing apparatus in the shape of Siemens' low resistance bridge, which is capable of indicating resistance to the one-millionth of an ohm. This present is all the more acceptable since it has been given in recognition of the tests done by Professor Jamieson's students during last session.

A feature of the Oerliken Works, Switzerland, is the electric balancing of turbines. There is a 600-horse power turbine, driving a three-phase dynamo. The balancing apparatus consists of a ring-field magnet wound with a single exciting coil, and firmly fixed above the apparatus to be counterbalanced. The shaft carries a ring armature, and when the turbine is running the attraction between this armature and the magnet is 42·6 lb. per square inch. The power required to operate the magnet is only about a third of a horse-power per ton of load carried.

In London 2358 births and 1211 deaths were registered last week. Allowing for increase of population, the births were 234, and the deaths 150, below the average numbers in the corresponding weeks of the last ten years. The annual death-rate declined to 14·4. During the four weeks ending on Saturday last the death-rate averaged 14·5 per 1000, being 2·5 per 1000 below the mean rate in the corresponding periods of the ten years 1884-93. In Greater London 3183 births and 1550 deaths were registered, corresponding to annual rates of 27·9 and 13·6 per 1000 of the estimated population.

Whilst in the Thames Valley the rainfall has been 1·72in. more in June, July, and August than in any year of the last twenty-five, it has been curiously small in the effective supply area of Leicester, where the water supply is rapidly diminishing. Both reservoirs are about 21ft. below the weir level, and even with a greatly diminished consumption on the one hand, and several auxiliary supplies on the other, the quantity in stock is so small that, unless something unexpected happens, not a drop will be left in stock on October 15th. Gangs of men are engaged night and day sinking wells near the river Soar, where it is hoped supplies will be found, and pumping engines are being prepared to force the water direct into the water mains without filtration.

America is now reported to have a moving mountain, that is, one which moves more than most of them. Near the cascades of Columbia it rises, a gigantic mass of dark basalt, six or eight miles long, and 2000ft. high, with a three-pronged pinnacle to tempt the adventurous. Year by year this mountain is moving down towards the river, and some day it will dam it, and form a vast lake. The forests at its root are being gradually pushed beneath the water, and are fringed with submerged stumps. The *Pall Mall* says the railway that runs along it is displaced to the extent, in parts, of 10ft. in a few years. The cause of the phenomenon is supposed to be a gradual subsidence of the soft sandstone at the base of the mountain, which is continually washed away by the swiftly-flowing waters of the Columbia river.

Researches on the movements of the solar atmosphere formed the subject of a recent paper in the *Comptes Rendus* by M. H. Deslandres. An examination of many photographs of spectra of the sun reveals interesting phenomena in connection with a bright line occurring within the wide dark lines H and K of calcium. This line may be resolved into two bright lines enclosing a dark line; the bright lines correspond to the lower layers of the chromosphere, while the dark line belongs to the higher layers. These bright lines often show dissymmetry, sometimes one and sometimes the other becoming the narrower. Spectra of the faculæ do not usually show this dissymmetry, but it is a common condition over the remainder of the surface, and is more pronounced near the equator than in the neighbourhood of the poles. Near spots the observed dissymmetry is often in the opposite direction on opposite sides, and the narrowing of the line is sometimes irregular. These phenomena can be explained on the hypothesis of a continual circulation of the sun's atmosphere, but *Nature* says it is worth noting that a less marked dissymmetry has been obtained in the calcium spectrum produced by the induction spark.

Some little time ago forty-three officers of metropolitan police were deputed to make certain observations concerning road traffic generally during the discharge of their daily duty in the busiest thoroughfares of the world. These observations extended over fifty days for twelve hours each day—namely, from 8 a.m. to 8 p.m.—and granite, asphalte, and wood pavement were considered. In one day of twelve hours no fewer than 12,366 horses and vehicles passed along Cheapside and 5350 along Cannon-street. During the fifty days upon which observations were taken 542 accidents took place on wood pavement, 719 on granite, and 1066 on asphalte. From these figures it was estimated by an expert that a horse could travel 330 miles on wood pavement during the fifty days without meeting with an accident, 191 on granite, and 132 on asphalte; therefore the great superiority of wood pavement over all others—at least, where horses are concerned—is at once apparent. Altogether, 1054 falls were recorded, and an analysis of this number, *London* says, affords some curious information. On asphalte 247 partial and 190 complete falls took place; on wood 326—only 39 complete falls. Roughly, for every fall on wood pavement four took place on granite and asphalte.

The recovery of the india-rubber from goloshes and similar articles forms an extensive branch of industry in the United States. The process by which this recovery is effected consists in the mechanical separation or destruction by means of dilute sulphuric acid of the textile materials and the subsequent treatment of the finely-ground product with steam under a pressure of six atmospheres. The steaming process seems to effect a devulcanisation by oxydation. This assumption is borne out by the fact of the regenerated india-rubber possessing, unlike vulcanised rubber, to some extent the plastic properties of natural caoutchouc, and also by the results of an analysis, which showed the presence of a large quantity of sulphates and but little sulphur in combination with organic matter in the recovered product. The *Journal* of the Society of Chemical Industry says various qualities of this regenerated or reclaimed rubber are met with in commerce. The price of these products, which at best represent but mediocre mixtures approaching closely in composition to the waste material from which they have been obtained, is high—1s. to 1s. 6d. per kilo.—considering the quantity of real caoutchouc contained in them does not exceed 35 or 40 per cent. Their industrial value, therefore, appears doubtful. Three samples in the shape of black sheets, examined by the author, had a specific gravity of from 1·59 to 1·66, and contained lead oxide, calcium sulphate and carbonate varying in quantity from 12·23 to 14·02 per cent., 21·43 to 22·13 per cent., and 10·91 to 18·00 per cent. respectively, together with small quantities of ferric oxide, alumina, silica, and water. The sulphur in combination with caoutchouc amounted to from 0·71 per cent. to 2·03 per cent.

## MISCELLANEA.

Messrs. Charles Churchill and Co., Cross-street, Finsbury, have been appointed special agents for the Brown and Sharp Manufacturing Co., tool makers, Providence, Rhode Island.

On Monday last the large hopper dredger, Percy Sanderson, recently built by Messrs. Wm. Simons and Co., for the European Danube Commission, arrived all well at Sulina, Roumania, after a quick voyage of 19½ days from the Clyde.

The Council of the Society of Engineers have unanimously elected Mr. Perry F. Nursey, a Past-president, and for thirty-six years a member of the Society, as honorary secretary and treasurer, in place of the late Mr. Alfred Williams, who had occupied the position since the foundation of the Society in 1854.

Messrs. W. H. Allen, Son, and Company, of Lambeth, have completed their new works at Bedford, and they are now in working order. The works are built on a site adjoining the main line station, one hour's ride from London. We hope shortly to give a description of these very interesting works, which are driven partly mechanically and partly electrically.

Another Niagara power development company has reached the stage where proposals for actual construction are invited. The work consists of a canal excavation about 7½ miles in length and involving the excavation of about 1,300,000 cubic yards of earth and 4,300,000 cubic yards of limestone rock. An average rate of work of 16,000 cubic yards of excavation daily is to be required of the contractors, at which rate about a year would be required to complete the excavation.

Our cruisers and gunboats seem to comprise a good many crocks. The Barossa is internally very ill; the cruiser Fox was on her eight hours' draught trial off Portsmouth on Wednesday, when she again broke down, and the trial had to be abandoned in consequence of a hot big end; and the gunboat Sharpshooter, which has been a great source of anxiety and expense to the Admiralty since she was first commissioned for sea, developed defects of so extensive a character following on her three-hours' commissioning trial off Plymouth on Monday that her further trials have had to be abandoned; and it is stated to be unlikely that she will be able to join the Channel Squadron on their forthcoming cruise.

A new graphic wire table designed by Mr. A. H. Howard has been issued by Messrs. W. T. Glover and Company, of Westminster and Salford. This table shows the dimensions of copper wires and cables in both decimals of an inch and in metric measurements, the equivalent sizes in solid and stranded wires, the fall of potential, the rise of temperature with given amounts of current, and other necessary information, all arranged in a simple and graphic form. The various wires and cables are arranged above one another in vertical columns according to their area, ranging from ·001in. to 1 square inch, so that all equivalent areas are shown in the same horizontal lines; while diagonal lines give the fall of potential per 100 yards upon any sized conductor with any current from 1 to 1000 ampères. A series of curves printed in red shows approximately the temperature of any conductor with any given current.

In Louisville, Ky., civil engineers are now required to take out a licence in order to practice, and must pay an annual licence tax of £2. In case civil engineers are associated in a firm or corporation, each member of the firm must pay a separate licence tax. *Engineering News* says: "It seems like a slur on the profession to require licences from those who follow civil engineering; but in several Southern States the old-time custom of raising revenue by laying a licence tax upon those who follow many special occupations is still kept up. Questions occur which have puzzled wiser people than the tax authorities of Louisville. Where is the line to be drawn between the civil engineer and the mechanical engineer; or suppose a man chooses to call himself simply an engineer, can he thus avoid the tax? Again, is the land surveyor a civil engineer, and does the engineer who is employed on a salary 'practise' his profession? Another unique idea which has been recently put in force in Louisville is the requirement that candidates for the office of city engineer must take an examination before a board, in which they must obtain a marking of at least eighty. The examination was one which would puzzle many an engineer of much experience." Evidently the city authorities of Louisville want to employ well crammed school-boys or schoolmasters and to pay for getting their town into a mess.

The French Channel Squadron—Escadre du Nord—is about to be thoroughly re-organised. According to the *Times*, the sea-going coast-defence ironclads Fulminant and Tonnerre, which are nearly twenty years old and proportionately slow, will be withdrawn, and their places will be taken by the new 17-knot coast-defence ironclad Jemmapes, 6590 tons, carrying two 13·3in., eight 3·9in., and fourteen quick-firing or machine guns, and by the new 19-knot armoured cruiser Latouche Tréville, 4750 tons, carrying two 7·4in., six 5·5in., and fourteen quick-firing or machine guns. The Victorieuse, a slow and weak armoured cruiser, dating from 1875, and having a wooden hull, will be temporarily supplanted by the steel armoured cruiser Turenne, and later by the Tréhouart, a sister ship to the Jemmapes. The Valmy, a third vessel of the Jemmapes class, will take the place of the sea-going coast-defence ironclad Furieux. Instead of the battleship Suffren, which has been afloat since 1870, either the Hoche, which is about to exchange her ordinary breech-loading guns for quick-firers, or the Brennus, which is the most powerful completed ironclad in the French navy, will be commissioned. The French Channel Squadron is already fairly well provided with modern unarmoured cruisers and light craft; but to the ships of these classes already flying the pennant there will presently be added the 19-knot cruiser Coëtlogon, 1850 tons, and the 18-knot torpedo despatch vessel Fleurus, 1310 tons. The 19-knot sister cruisers Isly and Jean Bart, 4160 tons, have quite recently been attached to the squadron, which, after the contemplated changes have been made in its constitution, will be exceedingly powerful.

The 30 calibre magazine rifle adopted by the United States army as a substitute for the old ·45 calibre Springfield rifle is to be used with a bullet made of 87½ parts lead, and 12½ parts tin. This bullet will be probably covered with a jacket of cupro-nickel steel as the German silver jacket, used abroad now instead of copper, permits too much deformation of the bullet. Recent tests show that at three yards range the German silver-jacketed projectile will penetrate only 5·3in. into oak, and was much deformed, while with the steel jacket the bullet penetrated 19·5in. to 24·2in. under similar conditions, and was not deformed. The copper-jacketed bullet was also much deformed. The ·45 calibre Springfield bullet gave only 3·2in. penetration at 50 yards. The "humane" purpose of this change in calibre and jacket metal is that the smaller calibre and harder casing of the projectile will disable rather than kill, as the ball will bore clean through a large bone with comparatively little shattering or "shock." As opposed to this theory, an American contemporary remarks that late German experiments have been made with the casing removed from the end of the ball, with the deliberate intention that the lead should "mushroom" on striking and increase the effect on the victim. The tendency in all armies is now to reduce the calibre, though nothing smaller than ·315 calibre has been yet used in actual warfare. Italy, Roumania, and Holland, have adopted a ·256 calibre; our own navy has selected a ·234 calibre, and gun barrels as small as ·197 calibre have been actually made. The United States new army ·30 calibre carries a ball weighing 220 grains, with a charge of about 37 grains of smokeless powder. For the benefit of some readers it should be stated that the calibre of small arms is here expressed in decimals of an inch.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

J. C. (Whitworth Scholarships).—*We hope to publish an article on the subject of your letter in an early impression.*

MAXWELL.—*Write to the Secretary, Institution of Civil Engineers, Great George-street, Westminster, and the Secretary of the Institution of Electrical Engineers, 28, Victoria-street, Westminster.*

H. M.—*You can have copper, silver, or nickel, deposited on the wooden model by any competent electro-plater. The surface is coated with blacklead, and on that the metal is deposited. Or you can prepare a paraffin mould of the model and have an electro-plate shell taken off that. The Elmore process is not in any way adapted for that kind of work. You cannot do better than apply to some of the large electro-plating firms in Birmingham.*

G. A. H. (Newtown).—*There is no difficulty in fitting ships with two sets of paddle-wheels. The Channel steamer Bessemer had them. The after paddles make a greater number of revolutions per minute than the forward wheels. But seeing that all the power needed by the very fastest paddle ships can be exerted through one pair of wheels, no sensible individual would use more. In the case of the Bessemer the whole central portion of the ship was occupied by the Bessemer swinging saloon, and one pair of engines was put forward and the other aft of this space. The ship was a failure, but not because the paddle-wheels were not efficient.*

C. E. R.—*The rapidity of fire of the Maxim gun is about as follows:—With weak Italian cartridges, 500 a minute; poor quality Russian cartridges, 550 a minute; English machine gun cartridges, 666 a minute; Martini-Henry, 650 a minute; American service cartridges, 775 a minute; with French smokeless powder with a muzzle attachment, at the rate of 1000 a minute, but has not been fired for a full minute. The fully automatic 1½in.—37 mm.—has a projectile which weighs slightly over 1 lb., and fires 300 rounds a minute. A 6-pounder fully automatic gun has been made with a belt feed; the rapidity of fire is at the rate of 200 a minute. Semi-automatic guns, such as 1½-pounders, can be fired about 25 or 30 times a minute. 45-pounders may be fired a dozen times a minute.*

### SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)*.. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* THE ENGINEER *is registered for transmission abroad.*

*A complete set of* THE ENGINEER *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
*Half-yearly* .. .. .. .. .. .. .. .. £0 18s. 0d.
*Yearly* .. .. .. .. .. .. .. .. .. £1 16s. 0d.
THICK PAPER COPIES—
*Half-yearly* .. .. .. .. .. .. .. .. £1 0s. 3d.
*Yearly* .. .. .. .. .. .. .. .. .. £2 0s. 6d.

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* THE ENGINEER.

### MEETINGS NEXT WEEK.

THE JUNIOR ENGINEERING SOCIETY.—Friday, October 5th, at the Westminster Palace Hotel, at 7.30 p.m. General meeting. Annual report of the Council. Election of officers for the ensuing session, &c.

THE SOUTH STAFFORDSHIRE INSTITUTE OF IRON AND STEEL WORKS' MANAGERS.—Saturday, September 29th, at The Institute, Dudley. First meeting of the session, when the President, Mr. Thomas Ashton, will deliver an address.

SOCIETY OF ENGINEERS.—Monday, October 1st, at the Town Hall, Westminster. Paper: "The Utilisation of Town Refuse for Generating Steam," by Mr. T. W. Baker, B.A., of which the following is a synopsis:—Present system of disposal—Destruction by fire, the recognised method—Component parts and quantity of town refuse—Theoretical evaporative value with and without sludge—Description of destructor furnaces—Steam generation in existing plants—Proposed new system for rendering the fumes innocuous and augmenting the steam pressure—Storage of heat and production of purified feed-water—Cost of working and net results.

### DEATH.

On September 22nd, at Southsea, suddenly, of heart disease, J. L. F. TARGET, C.E., aged 65.

# THE ENGINEER.

*SEPTEMBER* 28, 1894.

### GOVERNING ELECTRIC LIGHT ENGINES.

AT various times and from different quarters we receive letters complaining of the difficulty which the writers find in obtaining governors which will satisfy the demands of the electrician. Apparently every centrifugal governor in the market has been tried, and not one gives complete satisfaction. Are we to assume that the governor wanted cannot possibly be made, or that it is beyond the powers of inventors to produce one? We think neither solution of the difficulty is sound. The much desired governor is not forthcoming because the electric light engineers have not explained fully what they want, and—which is perhaps more to the purpose—why they want it. Let us endeavour to make good this deficiency.

The conditions under which electric light engines run are very trying. It is essential that they should always run at precisely the same speed, no matter what the load; or else the speed must be varied with the load in some definite ratio. Then the load varies from time to time through enormous ranges and with great rapidity. Thus, for example, we have an engine of, say, 350-horse power. It is developing 150-horse power. Suddenly, by the turn of a switch, perhaps a mile away, the load is doubled. Now if the engine is not prepared to take this instantly, without a check, the lights already on absorbing the 150-horse power first named will blink, and possibly drop very considerably in intensity, for some seconds. This blinking the public will not stand. It is a thing of all others to be avoided. Under some conditions of working, this engine, now with a load of 300-horse power instead of 150, must make precisely the same number of revolutions as before. If it runs a little faster the first lights may have too much current; if a little slower, too little. Under other conditions of working, the engine must run faster with 300-horse power than it did with 150, but the new speed must bear a precisely definite ratio to the old speed. Thus, then, we have two diverse sets of conditions. Under the first, the number of revolutions made per minute must remain unaltered, no matter what the load; under the second, the speed must bear an invariable ratio to the power. It will be seen that in either case the conditions are extremely trying.

When the ordinary centrifugal governor is used, no matter whether it acts on the throttle valve or on the expansion gear, a definite speed of engine accompanies each position of the governor balls. If the engine is making 100 revolutions and indicating 150-horse power, the circumference of the circle described by the centre of gravity of the balls has a given dimension. If the engine takes more steam and developes 200 or 250-horse power, then the circumference of the circle must be larger, for unless it is larger the throttle valve will not be opened further, but the balls cannot remain further apart unless the number of revolutions is augmented. Clearly, therefore, such a governor cannot comply with the condition of constant velocity of rotation of the crank shaft. Consequently, a centrifugal governor will not comply with one set of conditions. On the other hand, however, it might be made to comply with the second set of conditions, under which the speed is to vary with the power, if only a definite relation between the speed of the governor and the power could be commanded. It will not suffice to have a definite relation between the speed of the engine and the position of the governor balls. Only those who have tried to get a throttle valve or a Corliss governor to bear a definite relation in position to the power and the speed of the engine, can realise the difficulty of the problem to be solved. In practice a great deal has after all to be left to the engine driver, and he has to do the work that a properly made governor would perform. All this, it will be seen, applies to the action of the governor in keeping the engine to the normal rate and correcting the small changes in speed due to a thousand-and-one trifling irregularities of load, friction, steam pressure, &c. The great initial difficulty remains untouched, namely, the power of the governor to deal with lightning speed with large alterations in load. What appears to be needed is a governor which the moment the speed drops or rises—say 1 per cent.—will open the throttle valve full or shut it absolutely, and will then by a series of very rapid alterations or oscillations open and close it through smaller and smaller arcs until the new position suited to the load has been attained. Something quite analogous to this is found in the gas engine, and it is by no means certain that the same principle might not be applied with advantage to the steam engine. Messrs. Brown Brothers make an anti-racing gear for marine engines. Mr. Weir has, we fancy, something of the same kind. The moment the engine tends to race, the inertia of a small moving weight opens a trigger and the throttle valve closes. We have here the fundamental idea of a governor for electric light engines. The isochronal governor complies well enough with the conditions up to a certain point. The balls will remain in any position independent of the speed; it is only a change in speed that will cause them to move in or out, to or from the central spindle; but the isochronal governor is altogether too delicate a plant for the engine-house of an electric light station, and, besides, it is prone to "hunt" to a most distressing degree. On the whole, it appears to us that a modification of Pitcher's governor would best satisfy the conditions. This governor was at one time largely used by Fairbairn for regulating cotton mill engines. The principle involved is very simple. A piston driven by the engine works up and down in a cylinder, and pumps air under another piston in a second cylinder. The air escapes through a snifting cock. The piston rod of the second piston is jointed to the throttle valve. If the engine runs too fast the air cannot get away in sufficient quantity through the snifting cock; the second piston rises and shuts off steam. In the same way, if the engine runs too slowly, the second piston sinks and opens the throttle valve. By substituting water for air the whole apparatus can be reduced in dimensions, and a very obvious modification will put the governor into such a condition that the opening of the throttle valve may be anything for any speed, its position not depending on the speed, as is the case with the centrifugal governor, but on change of speed.

Whether the governor acts on a throttle valve or on the expansion gear seems to be a matter of no consequence, as far as governing is concerned; we have seen an expansion gear governor taken off and replaced by a throttle-valve governor with excellent results, and no appreciable difference in steam consumption. Throttle-valve governors generally fail because the valve is not properly constructed. There is no sort of relation between the area opened and closed and the position of the governor. The result is of course disappointing. The best arrangement, it appears to us, would consist in passing the steam through a circular orifice in a plate in which moves a cone. If this cone is sufficiently tapered a very long range of motion will be required to make any material alteration in the area opened for the steam to pass through. But if, instead of making the sides of the cone straight, we curve them, then it is obvious that we can establish what relations we please between the position of the governor and the area for steam admission.

It is quite beyond our purpose to go into matters of detail, our principal object has been to direct attention to a much felt want. Some electric light engineers are no doubt satisfied; but we often find that the satisfaction is based on ignorance. They do not know what a first-rate governor could do for them. Engine builders, again, often say that if the engine does not govern properly, the conditions under which current is generated are at fault and should be changed. The electrician's answer is simply, in some cases, that he cannot change them, and in others that he will not. We have ourselves no doubt that any competent inventor who would take the trouble to master the whole question could produce what is desirable. But the thing will never be done if a cotton mill engine is taken as a standard. The conditions to be satisfied are in essential particulars totally dissimilar. In what respects, the would-be inventor will do well to find out before he does any scheming.

### ELECTROLYTIC SANITATION.

A FEW years ago every new process of empirical character and doubtful merit was dubbed "electrical," much to the ultimate discouragement of legitimate enterprise. Names, not things, are mutable; and the same spirit of obscurantism has led to the wholesale adoption of the term "electrolytic" as the modern analogue of the older word. A similar effect on reasonable and well-considered methods involving the use of electrolysis is again apparent. Many persons, including those whose opinion is best worth having, are insensibly prejudiced against any suggested process bearing a name associated in their minds with much quackery and fraud; and a new electrical or electrolytic method has to contend with personal bias in addition to the ordinary physical difficulties which attend the establishment of all novel undertakings. The proper spirit in which to approach a matter of this kind consists in deliberately ignoring the association of ideas connected with its title, and in looking only to the method and its results—an attitude much aided by considering that electrolysis is only a particular means of effecting chemical change, and that the reactions attending or consequent on that change can be profitably discussed separately from their ultimate cause.

The strong advocacy and the unsparing condemnation which the method of sewage treatment proposed by M. Hermite has received in the lay and technical Press render it more than commonly necessary to adopt the attitude of impartial criticism to which we have alluded. With this attitude as our aim, it has seemed best to accumulate a sufficiency of data in the form of reports published concerning the process, both in France and in this country, before pronouncing an opinion having a greater value than that of a surmise. Such data being now available, a tolerably definite conclusion can be reached. Before dealing with the merits and shortcomings of the Hermite process, it is necessary to recall briefly its leading features in its present experimental form. Sea water is electrolysed with the formation of magnesium hypochlorite from the magnesium chloride naturally present, and the resulting solution, which has well-marked bleaching, oxidising, and sterilising properties, is used to flush water-closets, and to disinfect general household waste water. The ideas underlying the invention are the disinfection and sterilisation of fœcal matter in the act of passing to the sewer, and the preparation of the disinfectant from a cheap material occurring on the spot at all towns on the coast, and costing nothing but its freight when conveyed inland.

The apparatus adopted for the electrolysis of sea water —in order to convert it into a sterilising solution—cannot be usefully described here, published accounts being scanty and barely intelligible. This circumstance offers no obstacle to the consideration of the character of the reactions brought about, or to the discussion of the efficiency of the solution produced; and, indeed, only becomes of importance to a municipality contemplating the adoption of the system, in which case expert advice would presumably be sought. It is a matter of common knowledge that a bleaching and oxidising solution can be prepared by the electrolysis of magnesium chloride solution when the cathode and anode products are allowed to interact, and the temperature is kept below that which determines the formation of chlorate. For all bleaching solutions containing unstable chlorine compounds it is customary to measure their oxidising or chlorinating effect in terms of "available chlorine." Thus the quality of common bleaching powder, "chloride of lime," is estimated in this manner, a content of 35 per cent. of available chlorine being a normal amount present in a fresh sample of good quality. The Hermite solution may contain from 0·25 to 1·0 grammes of available chlorine per litre, *i.e.*, 0·025 to 0·10 per cent., stronger solutions being found uneconomical both in preparation and use. Choice between these strengths is much guided by the investigations of Dr. Alain Piton, of Brest, who has dealt with this and other points in a lucid report addressed to the municipality of the town in which he holds office. From his results it appears that a solution containing 0·025 per cent. of available chlorine is very unstable, while, when 0·05 and 0·075 per cent. are present the solutions keep well. Dilution of a strong solution with fresh sea water is to be avoided, as the mixture loses strength rapidly on account of the action of the chlorinated substance on the organic matter present in ordinary sea water.

It follows from this—and the matter is of sufficient importance to be insisted on—that sea water is a wasteful material to choose for the preparation of a bleaching and sterilising liquid, inasmuch as a notable fraction of electrical energy is expended in the early stages of electrolysis in oxidising the organic matter present, and it is only after this task has been accomplished that the formation of the active constituent takes place unimpeded. When once the solution has been prepared it can be diluted with clean fresh water without appreciable loss of strength other than that determined by the degree of dilution, *i.e.*, the total quantity of available chlorine in the diluted solution is sensibly equal to that originally present in the undiluted sea water. Transmission to a distance, and dilution on the spot where the solution is to be used, are therefore practicable. The electrolysed solution is perfectly efficient as a deodoriser, removing the characteristic smell of fœcal matter with rapidity and completeness. It has, however, but little solvent action upon solid fœcal matter and paper. In this connection it may be mentioned that a report published by the *Lancet* states that although there is but little solvent action on paper, yet that certain kinds, *e.g.*, newspaper, cause a loss of strength of the solution in contact therewith. Newspaper is no doubt particularly active in this respect, because of the impure woody character of the cellulose from which it is made (mechanical wood pulp being largely used), the substances other than cellulose which are present possessing considerable chemical activity, and suffering oxidation and chlorination more readily than cellulose itself. With regard to the quantity of solution needed for complete sterilisation, it was found that a given quantity of solid fœcal matter required about 3 per cent. of its weight of available chlorine—*i.e.*, 9 litres of 0·05 per cent. solution for a mass weighing 150 grams. With a solution of this concentration a period of ten minutes contact with the liquid was necessary, even longer being required with micro-organisms of resistant type. A natural consequence of this fact is that some device must be adopted whereby each flushing of a water-closet shall be kept in contact with the matter flushed out before both find their way to the street sewer—that is, there must be a filter basket or syphon in the soil pipe.

The investigation already referred to as having been carried out at the instance of the *Lancet*, adds certain conclusions to those arrived at by Dr. Piton. In this investigation an attempt was made to determine the nature of the constituents of the electrolysed solution. The strength in terms of available chlorine was determined by the standard method used for the valuation of bleaching powder, which consists in titration with a solution of arsenious acid, and the results were found to agree fairly with those obtained by measuring the quantity of iodine which the solution was capable of liberating from potassium iodide in neutral and acid solution. A large difference was, however, observed in comparing the amount of available chlorine determined by titration with arsenious acid, with that liberated by distillation with sulphuric acid, the first value being about half that arrived at by the second method. An explanation of this discrepancy is attempted by the erroneous statement that the available chlorine produced by the interaction of free hydrochloric acid and hypochlorous acid according to the equation $H\,Cl + H\,Cl\,O = H_2O + Cl_2$ is greater than that represented by the direct oxidising power of a hypochlorite in suffering reduction to a chloride, thus $Na\,Cl\,O = Na\,Cl + O$. So far from this being the case it is clear that the $Cl_2$ set free in the first equation is strictly equivalent to the O available in the second reaction. We should not have adverted to this mistake in chemistry on the part of our contemporary were it not that the matter has more than an analytical interest. If a Hermite solution contains an oxidising or chlorinating substance which is only capable of exhibiting activity on distillation with acid, it follows that it must contain some oxidised chlorine compound such as a chlorate, useless for disinfection and representing a waste of the electrical energy needed for its formation. Careful control of the process of electrolysis will therefore be necessary to avoid the production of useless substances of this type. There seems reason to believe that a part of the active substance present in the electrolysed solution is free hypochlorous acid instead of magnesium hypochlorite. This accounts for the activity of the solution being greater than that of chloride of lime of the same strength in terms of available chlorine, for in the latter instance calcium hypochlorite is undoubtedly present, accompanied by no hypochlorous acid save that liberated by the action of the carbonic acid of the air. This interesting distinction between the two chlorinated substances—chloride of lime and Hermite solution—is of direct practical significance. On the one hand, it explains the special efficiency claimed for bleaching solutions made by electrolysis, and proves it to be due merely to the presence of free hypochlorous acid, and not to any magical compound unknown to chemists and obedient only to the wand of the patentee, and on the other, leads directly to the preparation of what is termed an "artificial Hermite solution" in a manner vastly simpler than by electrolysis. By passing carbon dioxide into a solution of bleaching powder, the very feeble hypochlorous acid which is present in solution as calcium hypochlorite is set free, and the solution thus obtained is found to present the salient features of the Hermite solution prepared by electrolysis. In short, the latter may be regarded as a solution of hypochlorous acid prepared by taking advantage of the instability of magnesium hypochlorite.

The facts having thus been set forth, it remains to state the conclusions to which they lead. In the first place, there can be no reasonable doubt but that an actively oxidising and sterilising solution can be prepared by the electrolysis of sea water. Secondly, that this solution is unstable in the presence of oxidisable matter, exerting thereupon a well-marked action with considerable rapidity. Thirdly, not only dead organic matter but living organisms are attacked by this solution, and complete sterilisation of liquids containing even hardy bacteria can be effected, provided a large quantity of sterilising solution be used, and adequate time be allowed. Fourthly, all these results can be equally well produced by hypochlorous acid prepared by any well-known method. The whole question, therefore, is brought within very narrow limits. Only two phases need be closely considered. The first is whether it is desirable to sterilise human fæces immediately after their disjection. Seeing that many diseases are propagated by organisms passing from one human being to another by a circuit including the excreta of the diseased person, and the food or drink of the sound individual, only one answer can be returned. It is eminently desirable that immediate and regular disinfection of the excreta of all persons, hale or diseased, should be effected. How far the addition of the necessary disinfectant will affect the growth of innocuous organisms, whose important function it is to decompose and oxidise all waste organic matter in sewage on its way to or passage through a river or the land, is a matter which experiment only can decide. On account of the large dilution which excremental matter suffers from the addition of domestic washing waste and surface drainage by the time it finds its way into the main sewer, it is unlikely that the disinfectant added to the first-named material will be sufficient appreciably to retard the growth of scavenging organisms. Granting then that immediate and local sterilisation is desirable, the device of an effective system of flushing with the disinfectant selected may safely be left in the hands of the sanitary engineer. The second point for consideration is the best method of preparing a disinfecting solution of the requisite activity. Now, in this case there is one governing condition, and only one, viz., the cost of the process of manufacture. This vital question has not yet been dealt with by M. Hermite as explicitly as is desirable. One estimate states that 1 kilo. of available chlorine per hour can be obtained from an electrolyser absorbing 12-horse power. This, at the rate of ½d. per horse-power hour, equals 2·7d. per lb. of available chlorine. Another estimate gives one shilling per year as the cost of 40 litres of disinfecting solution per day. Taking the strength of solution at 0·05 per cent. of available chlorine, this is equivalent to 20 grammes of chlorine per day, or 7·3 kilogs. per year, corresponding with a cost of available chlorine of 0·75d. per lb., including, be it noted, the cost of distribution. The reconciliation of these estimates is a matter of some difficulty. Meanwhile, it may be observed that 35 per cent. bleaching powder at £8 per ton is equivalent to 2·4d. per lb. of available chlorine. To this must be added the cost of treating the bleaching powder solution with carbon dioxide—by no means an expensive item however. Thus it is plain that any process using hypochlorous acid as a disinfectant must, to compete successfully with bleaching powder, be manufactured at a rate not exceeding 3d. per. lb. of available chlorine produced. It is futile for any inventor to fall back upon the elegance and directness of an electrolytic process as distinct from one purely chemical. The brutal necessities of every-day life require a given end to be attained by the cheapest method, and take no account of purely æsthetic advantages.

### DEFECTIVE TORPEDO-BOATS IN FRANCE.

It will be remembered that a few months ago M. Lockroy made certain surprising declarations in the French Chamber of Deputies as to the condition of some of the vessels composing the French war fleet, and for thus exposing the weakness of the navy he was pounced upon by a crowd of writers who blamed him for his want of patriotism. The outcry against these revelations was the more bitter as at that moment some orders for ships were placed by the Governments of Russia and Japan with English firms, and it was stated that the allegations of M. Lockroy would deprive France of the business which she had been building up in the construction of war vessels for foreign Governments. A commission was appointed to make a thorough inquiry into the state of the navy, with special reference to the alleged defective torpedo-boats, and a report has just been drawn up by M. Lockroy for presentation to the Chamber. The report deals principally with the behaviour of the three torpedo-boats Nos. 167, 168, and 169. The first of these was ordered from Creusot in April, 1890, but exactly two years elapsed before the boat arrived at Toulon, and it was not until April, 1893, that it was delivered up to the Minister of Marine. No penalty whatever was inflicted upon the builders for the delay. Shortly after its reception it was found that the zinc sheathing on the hull was damaged, and the Government had to repair it at its own expense. The torpedo-boat 168, which was ordered about the same time as the preceding one, was not delivered until August, 1893. It was then examined in a dry dock, and it was seen to possess exactly the same defects. Six months afterwards an engineer discovered that the hull had become oxidised at the water-line, and was in some parts eaten through. A thorough examination of the vessel was then made, and it was not until May last, four years after the order had been given out, that the boat entered into service, and notwithstanding the repairs that had been made it seemed likely that the vessel would have to be again overhauled at an early date. The boat was accepted on condition that the builders should consent to a reduction in the price paid equal to about half what it would cost to have the hull thoroughly repaired. The torpedo-boat 169 remained a year and seven months before it was examined by the commission preparatory to official acceptance. Soon after its completion in August, 1892, it was found that no fewer than 300 rivets had not been properly zinced, and that the steel plates were likewise insufficiently protected. The boat was consequently sent back to the builders upon the understanding that the hull should be entirely re-sheathed. At the end of six months the work had not even been begun, and a voluminous official correspondence took place as to what should be done. The original decision to have the hull re-sheathed was reversed, and it was proposed to merely paint the hull, and to reduce the sum to be paid to the builders. As the efficiency of the boat was greatly impaired by its numerous imperfections, it became a question as to how much of the contract price should be deducted. Nothing so far has been decided, and the boat which was ordered in 1890 has not yet been delivered. In his report M. Lockroy also deals at length with the boilers of these torpedo-boats, and states that they are not placed in competent hands. Altogether he draws a very gloomy picture of these vessels, some of which, in their actual state, are quite unfit for service, but he thinks that a remedy would be found by keeping them in more active work, which would prevent the machinery and boilers from so rapidly deteriorating, and would at the same time afford more experience to those in whose charge they are placed.

### TRADE AND THE LABOUR PROBLEM.

Whenever the Duke of Devonshire addresses himself to trade questions his utterances are always of a sort commanding careful attention. The important position which this nobleman occupies as a capitalist deeply interested in iron and steel and shipbuilding manufacture, as also in colliery undertakings, invests his communications with especial weight. Some remarks which his Grace has made within the last few days at Staveley, in Derbyshire, on the labour position, evince an originality of thought and a weighing of surroundings which should appeal to manufacturers engaged in the industries we have mentioned, and to workmen in all parts of the country. The Duke of Devonshire is clearly to be reckoned among the number of iron and steel masters who to-day, in face of increasing competition from Belgium, Germany, America, and other of the world's manufacturers, view with alarm the demands of the operative classes. His Grace points out that there was a time when it was possible for English miners and ironworkers to strike and bring about the closing of collieries and ironworks without doing serious damage to the trade of the country. England's customers could not go elsewhere, for no other nation was in a position to supply them. But now all this is changed. Strengthened doubtless by the published testimonies of the iron and steel masters who recently visited Belgium with the Iron and Steel Institute, his Grace observed that we no longer possess a monopoly of iron and steel and coal manufacture and raising. Other countries have now learned to use their minerals in manufacturing processes, and their workpeople are as well trained as ours, both physically and mentally, perhaps in some cases better trained, to make the best use of their enterprise and resources. His Grace warns labour that by their ignoring of employers' interests in their demands for shorter hours and higher wages they may probably be taking a course which, instead of operating to their advantage, may result in there being no profits to divide at all.

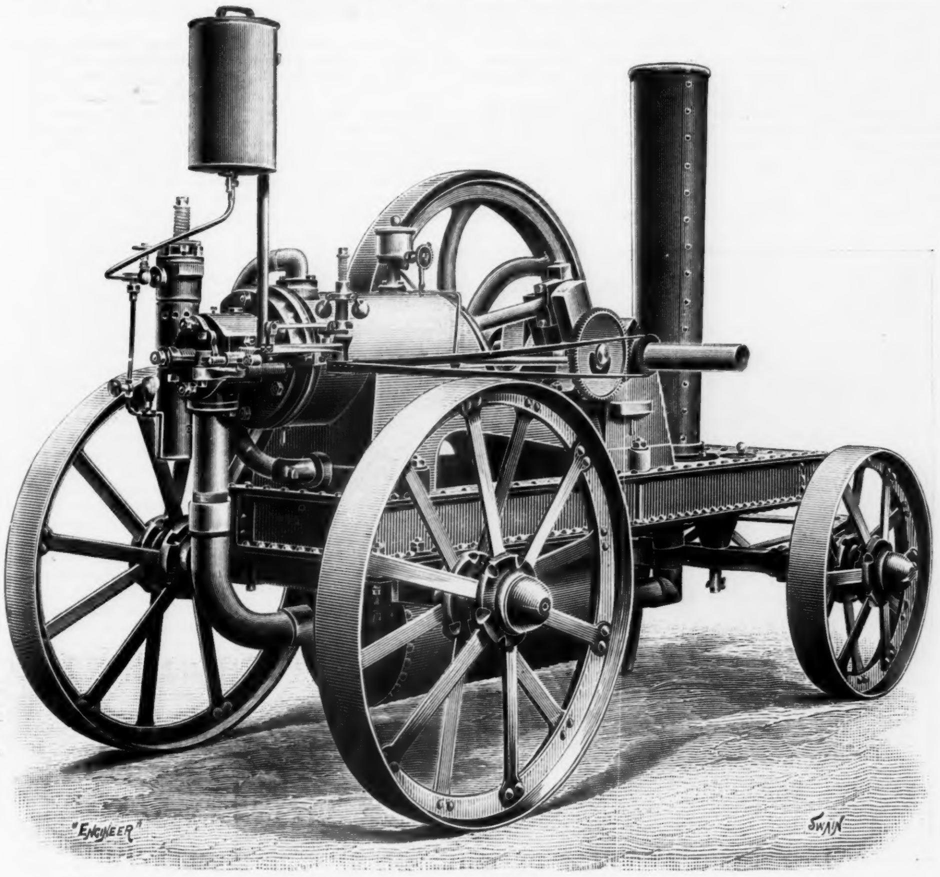
# THE CAMPBELL OIL ENGINE

THE CAMPBELL GAS ENGINE CO., HALIFAX, ENGINEERS



## THE CAMPBELL PORTABLE OIL ENGINE.

THE above engraving illustrates a new form of the Campbell portable oil engine which has been made since the trials at Cambridge in June last. The truck of the engine is made of two channel irons 7in. deep by 3in. by 3in., and the plates ¼in. thick. The capacity of water carried is 55 gallons; oil capacity is 30 gallons. The wheels of the truck are 4ft. and 3ft. diameter, made of wrought iron. The weight of the whole engine, complete with shafts, is 3 tons 2 cwt., as compared with the weight of the same size of engine at Cambridge, which was 4 tons 18 cwt., a very large reduction.

A cooling arrangement for the water supply is provided. The water is pumped out of the truck tank and delivered into the jacket of the engine, and from there taken by the pipes from the top of the water jacket to a perforated pipe situated in the hollow of the engine bed-plate. This bed-plate is cut away at the sides, and currents of air, caused either by the wind when the engine is working out in the open, or by the draught caused by the fly-wheels, act together to help to cool the water as it issues from the perforated pipe. The water on issuing from this pipe falls into an open space cut in the top plate of the truck; this also gives cooling surface to the water, but the exhaust is also utilised to induce a draught of air over the heated water. The round box shown underneath the truck is used to silence the exhaust. The driving arrangements are so made that a driving pulley can be put on either side of the engine, and a belt can be taken therefrom in either direction. The engine thus contains several improvements made in the last few months.

The engine itself is very similar to the fixed engine, but mounted on wheels and truck; and this Mr. Campbell considers the best method of making a portable oil engine. He thinks that for oil engine purposes sufficient strength and rigidity cannot very well be obtained with a cylinder bolted on a light wrought-iron truck, and entirely separated, except by two stays, from the crank bearings, as these engines must stand the hard wear and tear in agricultural or contractors' work. With designs such as that shown, the engine is in one part, and that part strong enough in itself to stand all working stresses without any chance of details moving out of position or out of line. It can, if necessary, be disconnected from the truck and used as a fixed engine with little trouble. Some well-known makers adopt this method in their portable steam engines. The engine illustrated is made by the Campbell Gas Engine Company, Halifax, and is of 8 nominal horse-power, giving, we are informed, 10 brake horse-power.

---

## THE DECAY AND FAILURE OF TAIL SHAFTS IN STEAMERS.

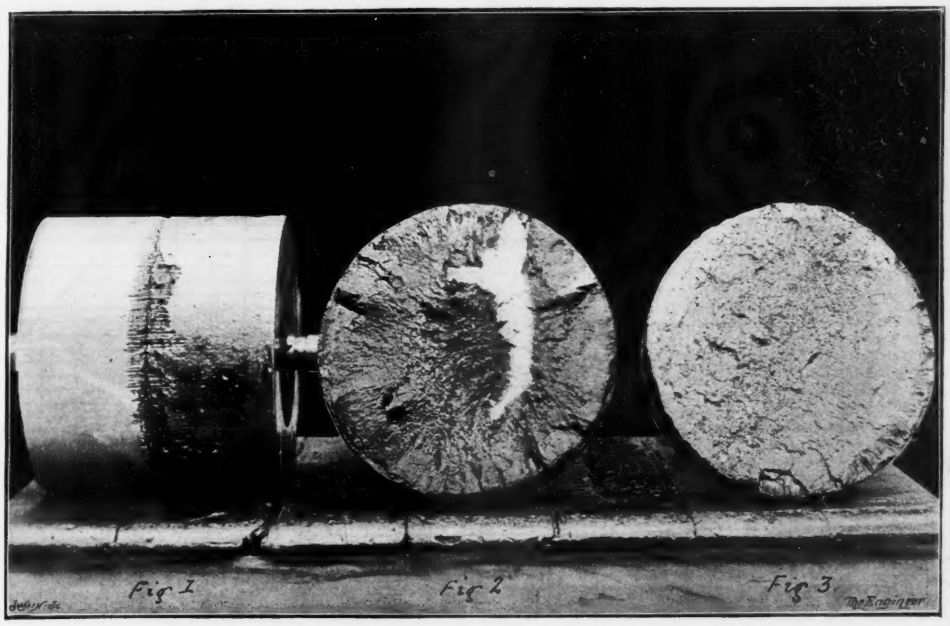
THE theory that the corrosion from which tail shafts suffer near the ends of the brass liners is induced by galvanic action has sometimes been assailed, and the breakage of the shafts attributed to other primary causes. It must be admitted that when a shaft has become corroded greatly throughout the length of the part exposed to the action of water between the liners, it becomes difficult to determine from that case alone what was the whole history of its failure. But when experience of a great number of shafts is accumulated, and a life history built up from numerous scraps of indisputable evidence, the theory referred to at the outset of these remarks appears to be amply justified.

Our illustrations, if at first sight of small significance, and such as are within the experience of thousands of engineers, are nevertheless interesting as representing actual examples of various stages in the life history of unprotected tail shafts. Fig. 1, perhaps more graphically than could be shown in any other way, illustrates a somewhat early stage in the process of decay. The object shown in this figure is a piece cut from a condemned tail shaft, and it has been turned so as to be mounted upon journals and preserved as a specimen. The left-hand portion of this specimen is the part on which the brass liner had been shrunk, and the right-hand portion is part of the exposed middle body of the shaft between the liners. This shaft had been less than two years in work, and the important thing to note about the illustration is that there is but little general corrosion of the part exposed to the action of water, but severe corrosion around a narrow zone just at the end of the part covered by the liner. This example, therefore, illustrates and bears out very conclusively the theory of galvanic action between the metals inducing the initial corrosion, and the fact of the corrosion proceeding largely in deep longitudinal grooves is a further proof of the decay being due to galvanic action, and not, as is sometimes asserted, to mere wash or eddying in the water, caused by the rotation of the shaft at the angle made by the liner with the shaft.

After studying this zone of corrosion in the region of the end of the liner, which is pretty equally distributed on both sides of the line formed by the end of the liner, we come to study what is of still more consequence, viz., the narrow but deep gutter or knife-like cut which has taken place immediately at the end of the liner, and which is very distinctly illustrated in our engraving. It would appear that the galvanic action inducing the corrosion is enormously more intense at the sharp angle of the liner where it meets the shaft than at a short distance away therefrom, resulting in this nicking of the shaft all round, and which is further illustrated in Figs. 2 and 3, but especially visible in the latter. Fig. 3 is a condemned shaft that was broken for fuller examination, and it will be seen that the shaft had been originally quite sound, but that the corrosion above alluded to had penetrated it to a depth of about 1in., and which is visible on the face of the break for about half-way round the shaft. It may be assumed that if the shaft shown in Fig. 1 had been broken it would have exhibited also just such a fracture as that shown in Fig. 3.

We then come to examine Fig. 2, which is a shaft that had been running for six years, and which had exhibited on the surface signs very little more disturbing than those shown in Fig. 1, excepting that the whole body of the shaft between the liners had become pretty deeply corroded, due to the longer time the shaft had been exposed to the action of water. Herein, perhaps, lies a considerable danger, viz., that the general corrosion here alluded to is apt to obliterate the appearance of deep local corrosion such as is shown in Fig. 1, by making it all appear general throughout the shaft. This shaft, however, was fortunately condemned, and it was broken by dropping a ball upon it to see what the fracture was like. It is one of the worst cases the writer has ever seen, inasmuch as the light-coloured vertical strip was all the sound metal left, although the shaft had been a thoroughly sound and good shaft originally. The whole of the remaining section of the shaft was fractured and discoloured, and it appears almost a wonder that the shaft could be lifted up in the crane without the thing falling in pieces, and yet it had been driving the propeller and was not suspected of being in this condition. It is not contended that the galvanic action and consequent corrosion above alluded to had penetrated to the heart of this shaft, and of itself caused the total destruction of the shaft, but that, given the initial local decay and nicking of the shaft by galvanic action and corrosion, as shown in Fig. 1, the strains due both to ordinary driving and the more severe ones due to heavy seas or running light ship, when the blades of the propeller frequently flop upon the flat surface of the water so as to cause shocks out of all proportion to the normal driving stresses, become concentrated upon this particular reduced section of the shaft, and, naturally, all the fatigue takes place there, and actual fracture then proceeds to the ultimate destruction of the shaft.

It is sometimes argued that when a shaft shows a broken fracture like that in Fig. 2 that it was of too light a section for its work. This, however, is by no means proved by the circumstances, and the addition of more metal subjected to the same conditions could have little effect in ultimately saving the shaft, though it might defer for a short time the date of its ultimate failure. The whole matter appears to be a sequence of events which bear one upon another. First a galvanic couple is formed between the brass and the iron, which in the presence of water induces corrosion at an abnormal rate. This corrosion penetrates a short distance straight into the shaft around the end of the liner, and so weakens the shaft like nicking a stick that it is intended to break over one's knee. This reduction of strength all in one plane at right angles to the axis of the shaft concentrates all strains upon that unfortunate section, and the ordinary work to which a tail shaft is subjected then proceeds to complete its ruin. Obviously, if the initial stages of this process can be averted there is hope, if, indeed, there is not certainty, of averting also the later stage; and it is this averting of the insidious initial stages of the process alluded to, that is the object of the tail shaft preserver patented by Mr. Mudd, of Hartlepool, and which has now been applied to the tail shafts of a large number of ocean-going steamers.



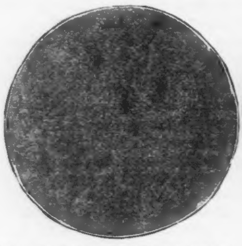
EXAMPLES OF CORROSION IN TAIL SHAFTS

The elastic sleeve, which is pulled over the shaft and cemented thereto, overlaps the end of the brass liner some 5in. or 6in., the liner being thinly tapered down to receive it, and thus the water is excluded from the shaft altogether in a very simple and cheap manner, the consequence being that no corrosion whatever can proceed at the end of the liner, or at any part between the liners. The strains, therefore, due to the work passing through the shaft are left to be distributed evenly throughout its length, and no dangerous nicking of the shaft at a particular section is at any time in existence when this sleeve is applied. A fracture occurring in a shaft thus protected would be one from a blow or accident, such as would fracture the shaft in any case, and would not be the much lighter shock that would be sufficient to shatter a shaft that has already been nicked around and reduced in sound section at one point by perhaps 20 per cent. of its area. The improvement implied by the adoption of this sleeve appears to be a small and simple one, but when one remembers the thousands of shafts that have failed from these causes, it becomes evident that in its results it is an exceedingly important matter, and one that should not escape the attention of shipowners and their superintending en-engineers. The india-rubber being in the dark, cool, and always wet, ought to last without "perishing" for a very long period.

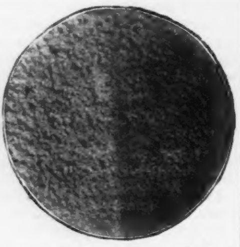
## THE COWPER-COLES GALVANISING PROCESS.

The Cowper-Coles galvanising process, which we briefly noticed in a former issue, has since that date been considerably developed, plants being now in course of erection with a bath capacity of some 14,000 gallons, capable of turning over forty tons of light work per week. Certain fallacies have long existed with reference to the relative merits of the dry and wet methods of galvanising. Zinc, as a protective coating, is unexceptional, on account of its electro-chemical relation to iron. The comparative inertia of lead to the chemical action of many acids has led to the contention that it should form as good, if not a better protection to iron than zinc, but in practice it is found to be very deficient as a protective coating against corrosion. A piece of lead-coated iron or terne plate cut from a sheet and placed in water will rust badly in the course of twenty-four hours, the water and plate being discoloured with a red oxide.

Iron coated with zinc by passing it through a molten bath of that metal has the somewhat misleading name of "galvanised iron," unless the term is taken as applying to the nature of the protective coating, not the process. The first method employed for coating iron with zinc was electrolytical; but it was soon abandoned in favour of the dry, or molten, process, as the results obtained were not satisfactory, and the process was found to be too slow and costly. With the object of cheapening the process of coating iron with spelter and of avoiding the deterioration of the quality of the material which usually follows pickling and hot galvanising, the application and the electro deposition of zinc has been the subject of many patents, as the records of the Patents-office bear ample evidence. Most authorities recommend a current density of 18 or 20 ampères per square foot of cathode surface, and aqueous solutions of zinc sulphate, acetate or chloride, ammonia chloride or tartrate, as being the most suitable for its deposition. Hermann's process has also been experimented with on a commercial scale; the chief feature being the addition of the sulphates of the alkalies or alkali earths to a weak solution of zinc sulphate. Electrolytes made by adding caustic potash or soda to a suitable zinc salt have been found to be unworkable in practice, on account of the formation of insoluble zinc oxide on the surface of the anode.



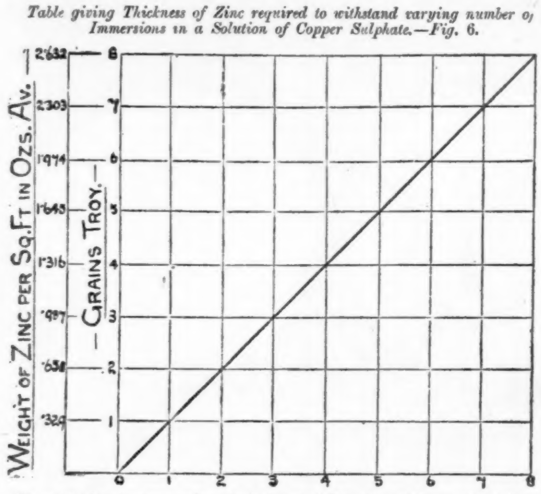
Zinc Coating Applied by Hot Galvanising Process—Magnified Five Diameters—Fig. 2



Deposit from Zinc Sulphate Solution (Acid — Magnified Five Diameters—Fig. 3

To all intents and purposes the deposits obtained from acid solutions under favourable conditions are fairly adhesive when great care is exercised in the preparation of the receiving surface; but unfortunately the zinc coating is of a transitory nature, its durability being incompatible with hot galvanising, as the deposit is porous and retains some of the acid salts which cause a wasting of the zinc and rusting of the steel or iron. Castings coated with zinc, in a similar manner, rust comparatively quickly even when the porosity has been reduced by oxidisation, aggravated by forcing some corroding agent, such as sal ammoniac, into the pores of the metal. The relative porosity of zinc coatings applied by different methods is shown by the above micrographs, Figs. 2 and 3.

*Table giving Thickness of Zinc required to withstand varying number of Immersions in a Solution of Copper Sulphate.—Fig. 6.*



No. of 1 Minute Immersions in Saturated Solution of Copper Sulphate

Other matters of serious moment are the slowness of ordinary electro-zincing, the trouble experienced in coating articles of irregular shape, and the trouble caused by the formation of loose dark-coloured patches on the work. These difficulties, and the unhealthy non-metallic look of the zinc coating obtained by the humid process, its want of brilliancy and glitter, has prevented ordinary electro-zinced articles finding favour with engineers and the trade for many purposes. The thickness of the zinc coating on different articles is for many purposes found to vary considerably, dependent as it is on a long immersion in the zincing solution, and consequently on the care of the workmen. Troubles have also been experienced from the scaling and furring up of the anodes, and the resultant increased electrical resistance, and the electrolytes are also constantly getting out of order, as more metal is taken out of the solution than could possibly be dissolved from the anodes by the chemicals set free on account of the rapid formation of an insoluble scale on the surface of the anodes. The illustration—Fig. 4—is a faithful representation of a portion of a zinc anode with scale over the metal core, averaging nearly ⅛in. in thickness. These difficulties are claimed to be entirely overcome in the Cowper-Coles process.

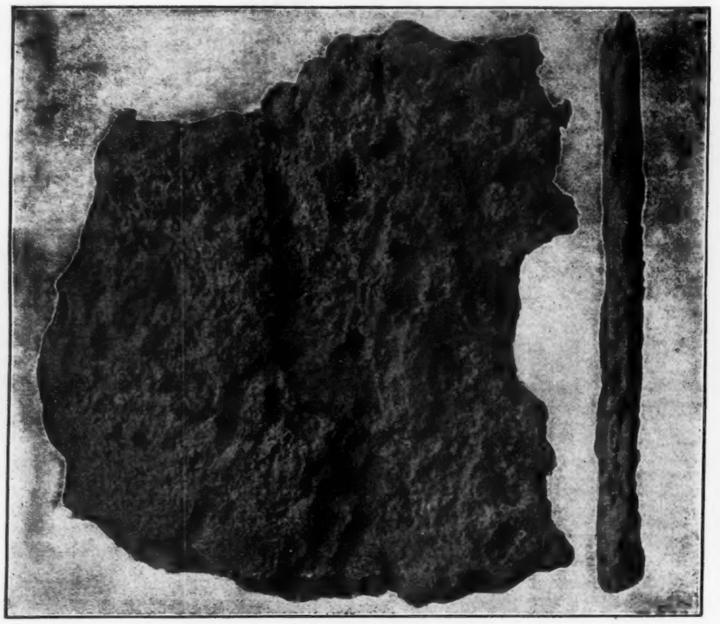


Fig. 4—PORTION OF ZINC ANODE, FULL SIZE

When galvanised iron is immersed in a corrosive liquid, the zinc is attacked in preference to the iron, provided both the exposed parts of the iron and the protected portions are immersed in the liquid. The zinc has not the same protective qualities when the liquid is sprinkled over the surface, and remains in isolated drops. Two metals in contact, in the presence of moisture, form a galvanic couple, and the result of the galvanic action set up under these conditions is analogous to that which takes place in a galvanic battery, viz., the electro-positive element is dissolved or corroded, while the electro-negative element remains unaffected or protected as long as the action continues; the intensity of the chemical action being governed by the relative position of the two metals in the electro-chemical series, wrought iron and steel gives rise to a feeble action; tin and iron and copper and iron standing some distance apart, give rise to decided galvanic actions, in which the iron, as the electro-positive metal, is corroded more rapidly if the coating is partially removed than it would if not coated. For similar reasons copper sheathing which was first used for wooden vessels of the English navy about the year 1770, is now insulated from iron and steel hulls by a wooden casing. With zinc and iron the position is reversed, and the results obtained diametrically opposite. Zinc is positive to iron, and consequently, whatever galvanic action is set up by their contact in the presence of moisture or other excitants, must have for effect the solution or corrosion of the zinc and the protection of the iron. Tinned iron is very durable as long as the coating of tin leaves none of the iron exposed, as in the presence of a film of moisture containing carbonic acid a galvanic couple is formed and the iron rapidly destroyed. Unlike tinned iron, galvanised iron resists the action of the weather to a remarkable degree, even when the coating is not perfect. The following tables show the electrical relation of the most common metals to one another in various solutions.—See Fig. 5, page 283.

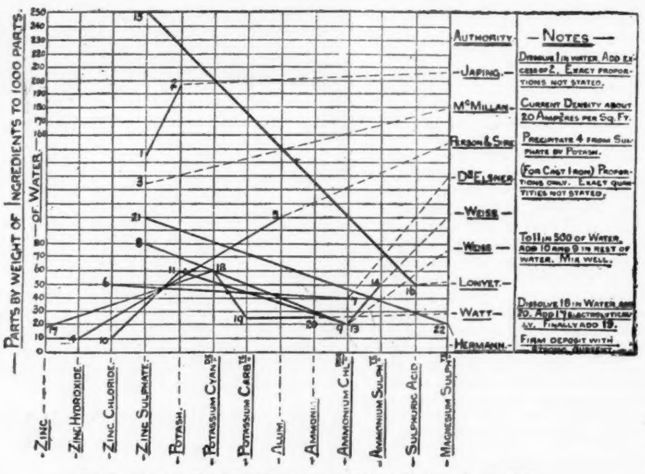

Fig. 1—Zincing Solutions Recommended by Various Authorities

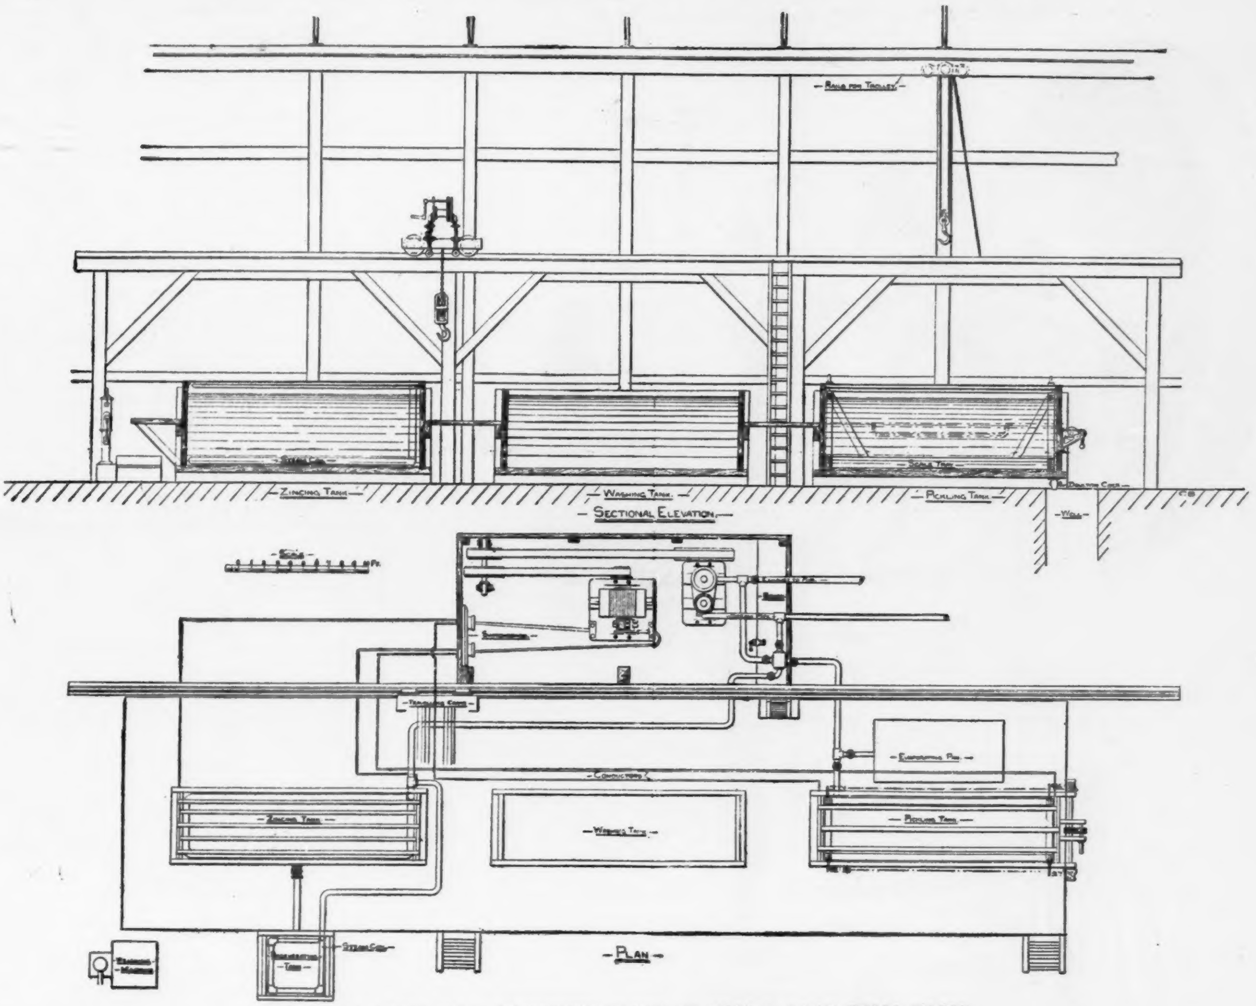
Zinc surfaces, after brief exposure, become coated with a thin film of oxide—insoluble in water—which adheres tenaciously, forming a protective coating to the underlying zinc. So long, therefore, as the zinc surface remains intact the underlying iron is effectively protected from corrosive action. Sea air, charged as it is with brine, is more destructive in its action upon galvanised ironwork, forming a soluble chloride. As zinc is amongst the metals most readily attacked by acids, ordinary galvanised iron is not suitable for positions where it is much exposed to an atmosphere charged with acids sent into the air by some factories, or to the sulphuric acids found amongst the products of combustion of coal and gas.'

The efficient protection of steel from chemical action is becoming a matter of considerable importance now that steel is so extensively taking the place of wrought iron, as owing to the increasing cheapness of steel, ironmasters are dispensing with the puddlers' services, and using steel instead of puddled bars for rolling down into sheets, hoop iron, &c. Thin steel plates are largely used for constructing the hulls of small craft, such as torpedo boats; but corrosion is found to be more marked in steel vessels than iron, for which reason some engineers still object to its use, or have the steel galvanised. Lieut.-Colonel G. Findlay mentions in his book, "The Working and Management of an English Railway," that the corrosion of steel rails as compared to iron rails is in the proportion of about five to four, and he has found in tunnels and manufacturing districts where sulphurous and other acid gases are present in the atmosphere the life of the rail is shortened to a material extent. The best preservative for iron is a covering of an electro-positive metal, as it is necessary for rapid rusting to take place to have an electric substance in contact, such as rust or oxide of iron, which acts as a negative element to the iron, and aggravates the process of rusting. The durability of painted ironwork, therefore, largely depends upon the surface of the metal being properly cleaned and prepared. Engineers recognise the fact that the best results are obtained when the paint is applied direct to the iron surface before it has had time to rust, as the rust prevents the intimate contact of the paint and induces chemical action, which causes the paint to peel from the iron. It has been found that this desirable end may be obtained at a very small cost by "zinc flashing," that is, coating the iron or steel, after pickling, with a thin coat of zinc, which will resist the inclemency of the weather, and retain a perfect surface for receiving a coat of paint until such time as it can be applied. A special feature of the cold process is that plates of very large dimensions can be readily zinced on one or both sides, which is a matter of some importance now that plates some 60ft. in length are being put in the straight line of steamers' hulls. The frames of such craft as torpedo-boat destroyers can also be galvanised after riveting up. The first cost of a plant having a bath capacity of 6700 gallons—30ft. by 6ft. by 7ft.—is found to be little more than a hot galvanising plant having a bath capacity of only 10ft. by 4ft. by 4ft. 6in. outside dimensions. The cost of such a bath is £125, and would hold twenty-eight tons of zinc, which at £17 per ton—£476—to keep this large quantity of zinc in molten condition, entails a heavy expenditure in fuel, the thickness of the iron bath averaging more than 1in.; moreover, the iron galvanising baths are also a constant source of annoyance and expense.

Both pickling and hot galvanising have the disadvantage of reducing the strength of wires, and of distorting and rendering brittle iron and steel of small section. By exposure to the lowest temperature of the galvanising bath—which averages some 1000 deg. Fah., the fusing point of zinc being 775 deg. Fah.—steel wire of high breaking strain has its hardness, and consequently its ultimate tensile strength and elongational efficiency reduced by the drawing of the temper and formation of an iron zinc alloy on the surface of the iron by as much as from 5 per cent. to 10 per cent. It is the practice, when coating steel wire, to keep the bath of molten zinc at as low a temperature as possible, and to run the wire through at a high rate of speed. Both these causes lead to a considerable waste of zinc by reason of the rapid solidification of the metal on the comparatively cold wire, and consequently the ready breaking or cracking-off of the covering metal on bending or twisting, owing to the difficulty with which molten zinc of low temperature adheres to the steel, except after prolonged contact. In some cases the wire on leaving the bath is wiped between asbestos rubbers; but steel thus treated is found to resist corrosion only for a short period. Many attempts have been made to electro-zinc wire, but it has not been found practicable to produce a wire capable of withstanding more than one immersion in a copper sulphate solution. Most manufacturers have ceased to galvanise the best classes of steel wire, which cost some £35 per ton, on account of the great risk there is of rendering it worth-

# THE COWPER-COLES GALVANISING PROCESS



Figs. 7 and 8—LARGE COLD GALVANISING PLANT AT MESSRS. LAIRD BROS.' WORKS

less, which is clearly a disadvantage, although the advisability of protecting the steel is unquestionable, as corrosion is found to be very marked on the inner strands. The zinc coating put on by the hot process is also uneven, and the increased weight is often a matter for consideration; the thickness can only be varied within narrow limits, the minimum weight of zinc being about 1¼ oz. per square foot, maximum 3 oz., except when the molten zinc can be raised many degrees above the most economical working temperature, and the articles removed gradually from the bath so as to give the zinc time to drain off before getting chilled, or in the case of thin sheet or wires, which are capable of having some of the zinc squeezed or wiped off by rollers or other suitable mechanical means. The weight of metal on lead galvanised sheets or terne plates is usually ¾ oz. per square foot. The following table gives the percentage increase of weight for different thicknesses of metal:—

*Percentage Increase of Weight due to Hot Galvanising.*

| Description of article. | Weight of zinc per foot. | Percentage increase of weight. |
|---|---|---|
| Thin sheet iron = ·025in. No. 22 B.W.G. .. | 1·196 oz. | 18·2 |
| $\frac{5}{16}$ Plates .. .. .. .. .. .. .. .. | 1·76 | 2·0 |
| 4in. cut nails .. .. .. .. .. .. .. | 2·19 (approximately) | 6·72 |
| $\frac{5}{8}$in. bolt and nut .. .. .. .. .. .. | 1·206 | 1·00 |

Tin is often added to the bath for the purpose of obtaining a smoother surface and larger spangles or facets, but it is found to shorten the life of the protecting coating considerably. A portion of a zinc coating applied by the hot process was found to be very brittle, breaking when attempts were made to bend it; the average thickness of the coating was $\frac{15}{1000}$ = ·015 of an inch. An analysis gave the following result:—

| | |
|---|---|
| Tin .. .. .. .. .. .. .. .. .. .. .. .. .. .. .. | 2·20 |
| Iron.. .. .. .. .. .. .. .. .. .. .. .. .. .. .. | 3·78 |
| Arsenic .. .. .. .. .. .. .. .. .. .. .. .. .. .. | Trace |
| Zinc (by difference) .. .. .. .. .. .. .. .. .. .. .. | 94·02 |

The filling up of the crevices and binding together of loose parts by dipping in a bath of molten zinc is sometimes taken advantage of for the purpose of making tanks water-tight instead of properly caulking them, and for hiding bad workmanship and welds; on the other hand, the soldering together of the twisted portion of wire netting adds much to its stiffness. A small quantity of iron is dissolved from all articles placed in the molten zinc; and a dross is formed amounting in many cases to 25 per cent. of the whole amount of the zinc used. The zinc-iron alloy is very brittle; it has been found to contain by analysis six parts of iron and ninety-four of zinc. The zinc is usually recovered by distillation in clay retorts; but some of the alloy is exported to India and elsewhere for casting small ornaments. There is no dross to be got rid of in such a process as that of Mr. Cowper-Coles. All but the very largest manufacturers have been prevented from having their own galvanising plants on account of the difficulties enumerated above.

The zinc coating put on by the cold process is, we are informed, found to resist the corroding action of a saturated solution of copper sulphate—Post-office test for telegraph wires—very much better than hot galvanised iron. A specimen of hot galvanised iron, having 1·48 ounces per square foot, withstood three immersions, whilst a similar piece of iron, cold galvanised, having 1·26 ounces per square foot, withstood five immersions, as shown in the following table. With equal amounts of zinc per unit of area, the zinc coating put on by the cold process is more resistant to the corroding action of a saturated solution of copper sulphate than is the case with steel coated by the ordinary hot galvanising process, and it may be inferred from this, that with coatings of zinc of equal thickness, the wire coated by the cold process will withstand the ordinary corrosion due to atmospheric influences much better than steel coated by the ordinary hot galvanising process, or, expressed in other words, steel coated by the cold process should have an equally long life to that of hot galvanised steel, with less zinc than would be necessary in the case of the ordinary hot process.

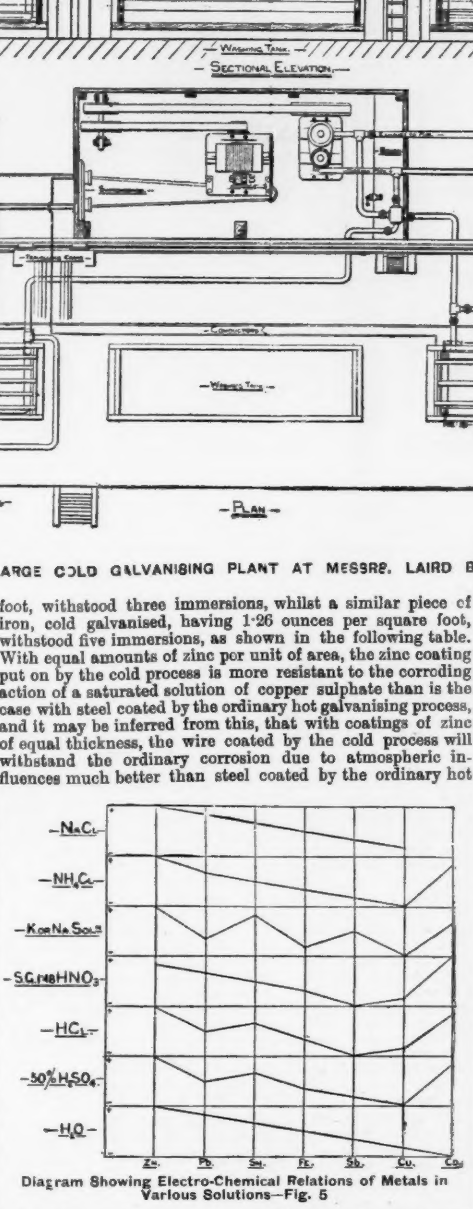


Diagram Showing Electro-Chemical Relations of Metals in Various Solutions—Fig. 5

*Results of Process Tests made on Samples of Charcoal Iron coated with Zinc by various Processes.*

| Process used to test the iron. | Grains per square foot. | Ozs. per sq foot. | No. of one minute dips samples stood without showing metallic copper. |
|---|---|---|---|
| Hot galvanising .. .. | 648·5 | 1·48 | 3 |
| Acid bath Zn $SO_4$ . | 446·4 | 1·02 | 4 |
| Cowper-Coles process | 552·64 | 1·26 | 5 |

The hardness of the zinc surface is a matter of considerable importance. With this object in view aluminium has been added from a separate crucible to the molten zinc at the moment of dipping the article to be zinced, so as to form a compound surface of zinco aluminium, and to reduce the formation of ashes to less than the usual amount when protective coverings are used of sal ammonia, fat, or glycerine. The addition of the aluminium also enables a thinner coating of zinc to be applied. Cold and hot galvanised iron should stand abrasion equally well, the thickness of the coatings being the same, the hardness of the zinc applied by the wet and dry methods, as determined by means of the Schlerometer, being equal:—Cold galvanised sheet, 6·0; hot galvanised sheet, 6·0; terne plate, 2·0; tin-plate, 2·0. The figures represent the load in grammes upon a diamond point, just sufficient to cause it to scratch the specimens.

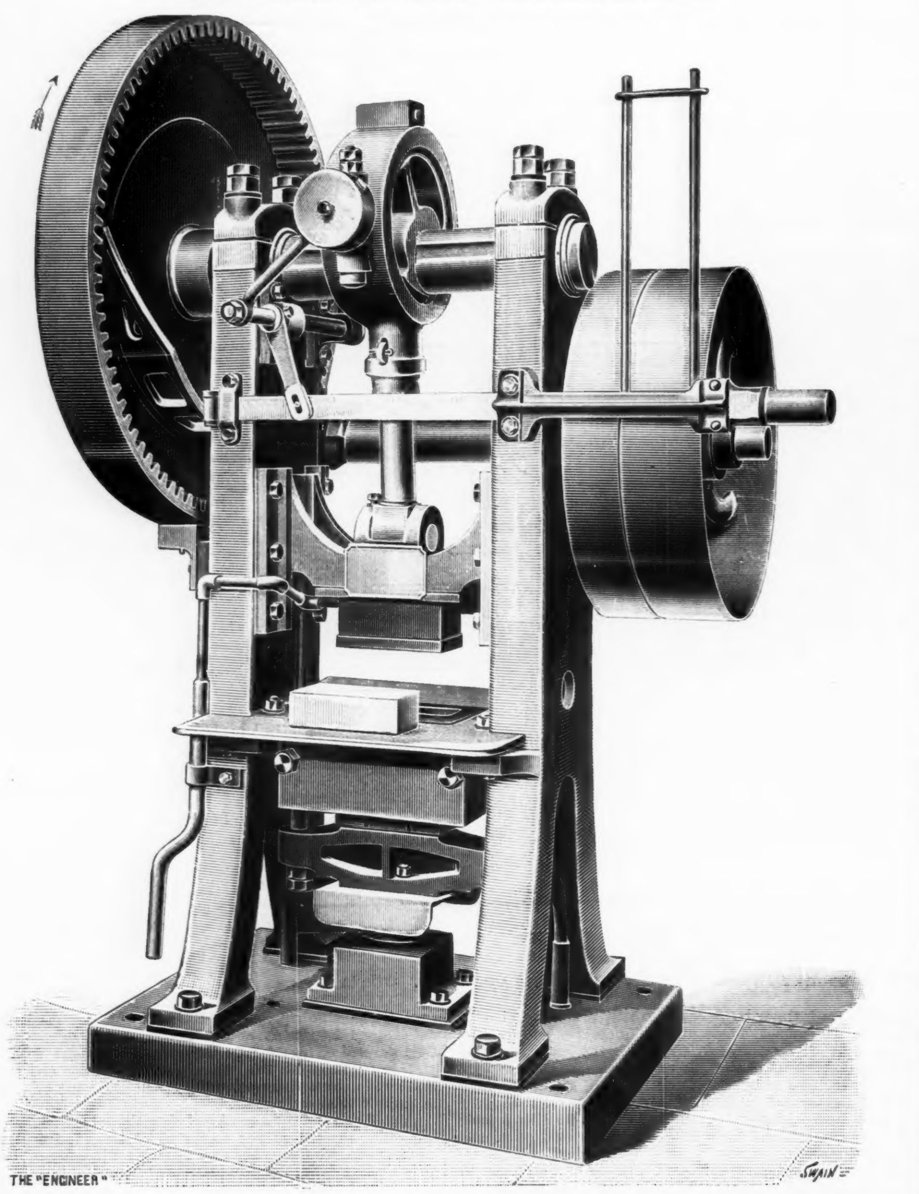
Figs. 7 and 8 show a sectional elevation of a cold galvanising plant erected at the works of Messrs. Laird Bros. at Birkenhead, who were the first to adopt the process, for the purpose of zincing the skin plates and frames of torpedo-boats and torpedo-boat destroyers. The baths are capable of dealing with plates 18ft. long, and have a capacity of about 4000 gallons. The heavier classes of work are transferred from the vats by an overhead carrier, the lighter by a trolley running on rails. The total current available is over 2000 ampères at an electromotive force of 5 volts. The current is conveyed to the tanks by bare copper rods. The pickling tank, which contains a very dilute solution of sulphuric acid, is heated by steam jets, the spent liquid being recovered in an evaporating pan as shown in the illustration. The articles after pickling are passed through the washing or oxidising tank, and then placed in the zincing tank, which is heated with a steam coil, into which live or exhaust steam can be passed. One ounce of zinc per square foot is found to afford sufficient protection for most purposes. The plates, after removal from the zincing vat, are ready for riveting into the vessel under construction, as they do not require drying or stoving.

---

EARTHQUAKE AT CONSTANTINOPLE.—Some observations of M. D. Eginitis, communicated to the *Académie des Sciences*, by M. F. Tesserand, respecting the recent earthquake at the Turkish capital, are of considerable scientific interest. We extract from our contemporary, the *Annales Industrielles*, the following account of the conclusions at which that gentleman has arrived. On the 10th July last, at twenty-four minutes past noon, mean local time, a severe seismic dislocation shook Constantinople and its suburbs. By collating the different observations he was able to make on the ground, by availing himself of a full use of the official dispatches, and by pressing into his service a large mass of miscellaneous valuable information on the same subject, M. Eginitis has formed a tolerably exact idea of the extent and intensity of the phenomena at distant localities, and has traced the course of the isoseismic curves. The depth of the focus of seismic action, he estimates, according to the rules laid down by Dutton and Hayden, to be 21·25 miles, a distance which, according to Mallet's earthquake formulæ, would be somewhat less on similar bases. By the aid of the observations made in France, Russia, and Roumania, he has, it is stated, been enabled to calculate the velocity with which the successive shocks of the earthquake were propagated. Commencing with Paris, he ascertained that the shock reached that city with a velocity of 1·875 miles per second. In the same unit of time the speed at Pavloxsk was 2·178 miles, and 2·25 miles at Bucharest. It may be regarded as established beyond doubt that premonitory signs invariably act as avant-couriers to the actual shock of the earthquake itself. M. Eginitis draws attention to the period of seismic action which for about the last two years has traversed the eastern portion of European territory. The Isle of Zante was the first sufferer, then came Thebes, followed by Lochrida. Constantinople was the next victim, and Sicily completed the list. In addition to these great shocks, a very considerable number of minor disturbances occurred during the same time in various localities, in both the East of Europe and Asia Minor. It is worthy of notice that the places previously cited are all situated in nearly the same straight line, and are moreover located in a part of the terrestrial surface which has been subjected to important geological transformations and dislocations.

# BRICK AND TILE PRESS

## MESSRS. BRADLEY AND CRAVEN WAKEFIELD, ENGINEERS



## BRICK AND TILE PRESS.

MESSRS. BRADLEY and Craven have just brought out a new steam power brick and tile press of which we give an engraving. The internally geared wheel on the press shaft is fitted with a cam or inclined plane; this comes in contact with the end of the bar carrying the belt guide forks at every revolution, and shifts the belt on to the loose pulley. The wheel has an adjustable balance weight to overcome the momentum of the wheel and stop the excentric when it gets to the top of the stroke, or before the crosshead has commenced its downward stroke. The piston being stationary with the excentric at its full stroke, there is no danger of the attendants getting their fingers caught in putting in or removing the bricks; the press cannot start again until a lever on the belt guide bar is operated. If desired, however, the press can be made to start automatically in the following manner: The spur wheel has in this case a longer inclined plane or cam; this cam knocks off the belt at the given time and place, but the momentum of the wheel carries it until the inclined plane passes the end of the belt guide bar, and by placing a weight on the starting lever the leverage of this weight moves the guide bar and the belt is put on to the fast pulley, and work is carried on with only a slight pause when the belt is on the loose pulley during the time the guide bar is travelling over the inclined plane in the wheel. The press is in daily operation at the maker's works.

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

*Electric locomotives.*—Electric locomotives will be used to haul trains through the new tunnel under the city of Baltimore; and the first of these has been built. It has two four-wheeled trucks or "bogies," each fitted with two electric motors of 200-horse power. These motors are carried on springs, and connected with the driving axles by flexible connections. The power plant will consist of four Corliss compound engines of 750-horse power each, coupled direct to four multipolar direct-current generators of 700-horse power each. These will furnish the current for the locomotives and for lighting the tunnel. Steam will be supplied by eleven boilers of 250-horse power each, operated under forced draught; the products of combustion escaping by a steel smoke-stack or chimney 50ft. high. For lighting the new station, &c., there will be eight arc-light dynamos of fifty-lights capacity, and incandescent generators of 2000 lamps capacity.

*Hydraulic dredge.*—On one section of the Chicago canal, which is being cut through a soft black loam, the excavation is being done by a hydraulic dredge. From a derrick frame at the front end of the barge is slung the end of a 20in. pivoted suction pipe 40ft. long, the inboard end of which is connected by a universal flexible joint with the fixed suction pipe. The outboard end is fitted with a revolving drum, concentric with the pipe, which drum carries on its periphery a number of steel cutters or blades, inclined so as to throw the material inward to the mouth of the pipe. The drum is 5ft. diameter and 4ft. long. On the barge is a 6ft. centrifugal pump, which draws the water and earth—5 per cent. to 30 per cent. solid matter—through the suction pipe, and discharges it through an 18in. discharge pipe supported on pontoons and leading to the shore, where it is deposited outside the levées built along the canal. The barge is 105ft. long, and 33ft. beam. The pump is driven by a 250-horse power engine coupled direct to the pump shaft, and the same engine also drives the cutting drum and the hoisting and winding drums. The barge is fed forward by an inclined stern spud connected to the ram of a hydraulic cylinder, and the vertical spud upon which the barge turns in cutting is also operated by a hydraulic cylinder. The dredge is worked continuously day and night, with occasional stoppages to clear the cutters from long grass and bulrushes, or to remove boulders from the pump. The excavation averages 450 cubic yards per hour, but nearly 600 cubic yards per hour have been excavated.

*Railway statistics.*—Statistics just issued for the year 1893 show 177,753 miles of railway in operation on December 31st, 1893, an increase of 2549 miles. A general summary is given in the following table:—

| | 1893. Miles. | 1892. Miles. |
|---|---|---|
| Mileage of railroads .. .. .. .. | 175,441·77 | 171,804·72 |
| Second track, sidings, &c. .. .. | 53,410 89 | 49,823·81 |
| Total track .. .. .. .. | 228,852·66 | 221,628·53 |
| Steel rails in track .. .. .. .. | 191,717·71 | 182,710·76 |
| Iron rails in track .. .. .. .. | 37,134·95 | 38,917·77 |

During the eleven years 1883-1893, inclusive, the average receipts per passenger per mile declined from 2·422 cents to 2·046 cents; the average receipts per passenger fell in like manner from 66·14 cents to 49 60 cents; the average receipts per mile of railway quite regularly declined from 1934 dols. in 1883, to 1721 dols. in 1892, but rose to 1799 dols. in 1893, just as it rose from 1645 dols. to 1693 dols. during the cessation of railway building in 1885-86. The average number of passengers carried per mile of railway was 2923 in 1883, and 3627 in 1894. The average distance travelled per passenger in 1893 was 24·24 miles, against 27·31 miles in 1883. The mileage run by freight trains was 350,108,255 in 1883, against 531,340,754 miles in 1894, the same general mileage of railways operated being taken as for the passenger traffic. The freight carried for the same two years increased from 400,453,439 tons to 757,464,480 tons, and the freight movement increased in like manner from about 46,000 million miles to over 90,000 million miles. The freight rates have been very steadily decreased in this period, as is shown by the following table for the two extreme years:—

| | 1883. | 1893. |
|---|---|---|
| Average receipts, ton, per mile .. .. .. | 1·224 cents. | 0·893 cents. |
| ,, ,, per ton .. .. .. | 134 72 cents. | 106 74 cents. |
| ,, ,, freight, train mile .. .. | 154 09 cents. | 152·16 cents. |

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THE October quarterly meetings of the Midland iron trade are fixed for the 10th and 11th of next month in Wolverhampton and Birmingham respectively. To these gatherings the iron market is looking with marked anticipation, ironmasters being very desirous to gauge on the occasion of these fixtures whether the revival which has set in will be maintained during the winter. There is a general impression that prices at the quarterly meetings will be strong, both in the raw and finished iron departments, and makers in neither branch are anxious just now to book forward. Marked bars are firm at £7 10s., second branded qualities £6 10s., and common bars £5 10s. Galvanised sheets continue active at £9 15s. to £10 for 24 w.g., f.o.b. Liverpool, while galvanising doubles are sharing in the improvement at £6 12s. 6d. to £6 15s., and £7 5s. to £7 7s. 6d. respectively. Hoops are strong at £6 10s., and thin strip and angles at the same figure. Gas tube strip is quoted £5 15s. Best Yorkshire engineering iron, delivered into this district, is quoted £17 10s. for bars, and £22 10s. for plates, but only meets with a limited demand from the best engineering houses. Pig iron prices continue rigid, and several producers have sold their output to the end of the year. Staffordshire all-mine hot-blast is quoted 55s. to 57s. 6d.; part-mines, 41s. 6d. to 42s.; and cinder, 38s. to 40s. Northamptons are quoted 41s. 6d. to 42s.; Derbyshires, 42s.; and Lincolns, 43s.

It is a matter for gratification that the manufactured iron production of this district continues to be nearly a quarter of the whole make of the kingdom, and even with regard to pig iron the falling off, it is to be noted, has not occurred within very recent times, the present output of this district being very nearly the same as it was ten or twelve years ago. Hence the recent sensational talk about the decay of the iron trade applies more forcibly to other iron-making centres rather than to the Midland district.

The best piece of news for trade this week is the intelligence that, instead of being dismantled, as at one time was feared would have to be the case, the blast furnace plant of the new British Iron Company has found a purchaser in the person of the late general manager of the company, acting for himself and other capitalists with him. Only the manufactured iron and steel works will, therefore, now be broken up. The news of the purchase is among the best that has had to be recorded in this district in connection with the iron trade for many a day, and experience has shown that there is yet plenty of money to be made out of the raw iron branch of the Staffordshire trade, whatever may be the probable fate in store for the manufactured iron business. The competition of the Derbyshire, Leicestershire, Nottingham, Northampton, and Lincolnshire pig iron makers with the South Staffordshire producers is, of course, a factor to be reckoned with which was non-existent ten years ago.

Considerable comment has been occasioned in engineering circles here by the paragraph in last week's ENGINEER on the American method of machinery erecting in foreign markets. Local firms will not have it that the strictures passed by the South American correspondent on English practice are deserved, and suggest that the pronouncement was guided by an exceptional instance. At the same time, I am myself bound to say that in other departments of manufactures I am constantly hearing of complaints of the superior packing and mode of turning out American manufactures, compared to British work in the Colonies and elsewhere abroad, though I have not previously heard that the matter extended to machinery erecting.

Much interest has been excited in a communication which has this week been made by Mr. I. C. Sharp, of Corporation-street, Birmingham, on the question of light railways or tramway construction in the agricultural districts. Mr. Sharp suggests that the best method of construction would be laying them down on the spare land on the sides of the public highways with the gradients adapted to that of the roads, where practicable, so as to reduce the necessity of excavating. The rate of speed should be about ten or twelve miles an hour, and the motive power could be either steam or electricity. In Mr. Sharp's opinion there is no doubt that in the immediate future electricity will prove the cheapest and best, and that the various streams of water about the country will be used for driving the dynamos to generate the electricity required for the purpose. There has not for some years, he points out, been any competition between existing British lines, so far as the traffic charges are concerned, and the investment of the new construction would be a safe and profitable one. In Belgium, where the cost of light railways has been £1500 a mile, including full equipment, the capital is subscribed in the following proportions:—The State, 27 per cent.; the provinces, 28 per cent.; the communes, 40·9 per cent.; and private individuals, 4·1 per cent. He suggests that County Councils should be empowered by Parliament to authorise construction, and to find the money for the same.

The value of mechanical coal cutters was debated on Monday at the North Staffordshire Mining Institute. Mr. B. Woodworth, of Fenton, suggested that such machinery should be introduced into the North Staffordshire mines for getting the thin seams. These at present cannot be got at a profit by hand labour, but machine cutting would, Mr. Woodforth suggested, overcome this difficulty. An important debate followed, in which it was stated that the chief trouble in working the seams was their inclination. Some seams of 2ft. thick were being worked in the district, but only after considerable persuasion of the men, who could hardly be got into them, and it was thought to be scarcely possible to get mechanical coal cutters to work, considering the inclination of the strata referred to.

Some startling information concerning a revolution in the present method of preparing the raw materials necessary in pottery construction, and which it is stated will be of the utmost importance to machinery makers, inasmuch as it will displace a great deal of the heavy grinding machinery now used, comes from North Staffordshire. It is stated that by the adoption of certain new laboratory discoveries on the behaviour of various materials at different degrees of temperature, and the chemico-electric treatment of certain of them, the ponderous and expensive grinding machinery now erected at British pottery works will be rendered obsolete, and a net saving in the present methods of manufacture obtained of "about two-thirds." Pottery ware which has been experimentally made by the new process on the Continent is credited with being much purer in colour than that hitherto manufactured, while the loss during the firing in the ovens is reduced to a minimum. Particulars of the new discoveries are awaited with great interest.

## NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

*Manchester.*—The general position throughout the engineering and iron trades of this district has undergone no material change during the past week. As reported in my last notes, further buying in the pig iron market at the advanced rates has slackened off, but makers are very firm, and show no disposition to entertain offers where they are put forward at under their quotations. Finished ironmakers are in a stronger position as regards their order books, but specifications come forward very indifferently. The steel trade shows some improvement, but it is difficult to say whether this is due to the stoppage of production in Scotland or to actually increased requirements. Amongst engineers there seems to be a more hopeful tone as to the future, and here and there increasing activity is reported. The position, however, remains generally very much what it has been for some time past, and the out-of-work returns of the trades union organisations do not as yet show employment to be any better.

The Manchester Iron Exchange on Tuesday was moderately attended, but for the most part only a slow business was reported. For pig iron there are still fair inquiries stirring, and business to a moderate extent might be done at a little under current rates, but as makers are not at all anxious sellers, low offers do not result in transactions being put through. In pig iron Lancashire makers still quote on the basis of 40s. for forge to 42s. for foundry, less 2½, at the works, or equal to 42s. for forge and 44s. 6d. to 45s. for foundry, less 2½, delivered Manchester district, and occasional orders are secured at these figures. District makers report only a very limited business coming forward; but, except that forge Lincolnshire is a trifle weaker, prices are very firm at full quotations. Delivered equal to Manchester, Lincolnshire averages 39s. to 39s. 6d. for forge to 41s. for foundry, and Derbyshire foundry about 45s. 6d. to to 46s., net cash. Outside brands offering in this market are fully maintaining their prices, good-named foundry Middlesbrough not being quoted under 45s. 4d., net cash, delivered Manchester, and business is done at this figure. With a steadily decreasing quantity of Scotch iron obtainable, anything like definite prices are scarcely quotable, but sellers who have anything to offer are not disposed to come below 49s. to 49s. 6d. for Eglinton, and 51s. to 51s. 6d. for Glengarnock, net prompt cash, delivered at the Lancashire ports.

The finished iron works in the district continue only indifferently employed, as notwithstanding makers' books are fairly well filled, specifications on account of orders come to hand but slowly. Prices, however, remain very firm at £5 7s. 6d. to £5 10s. for Lancashire and North Staffordshire bars, £7 to £7 5s. for Lancashire and Staffordshire sheets, and £5 17s. 6d. for random to £6 2s. 6d. for special cut lengths of Lancashire hoops, delivered Manchester or Liverpool.

Nut and bolt makers still report the weight of business doing improving, but no better prices obtainable.

In the steel trade hematites show a hardening tendency, the minimum quotations being now 53s. to 53s. 6d., less 2½, for good foundry qualities, but ordinary Bessemer basic billets can still be bought at £4 net cash delivered here. Steel bars are quoted at £6 to £6 2s. 6d., and steel boiler-plates £6 7s. 6d. to £6 10s. for delivery in this district.

In the metal market there has been a rather unexpected advance of ¼d. per lb. on manufactured goods during the past week, and list rates for delivery in the Manchester district are now as under:—Solid drawn brass boiler tubes, 6d.; solid drawn brass surface condenser tubes, 7½d.; solid drawn copper tubes, 7½d.; brazed copper gas and steam tube, 7¼d.; brazed brass gas tube, 6½d.; brass wire, or rolled brass, 5½d.; copper wire, 6¾d.; sheet brass, 6½d. per lb.; strong copper—sheets—55s. per cwt.

Amongst a few interesting items that I have come across during the past week, I may mention a new patent wood-working machine which is being introduced by Messrs. T. and R. Lees, of Hollinwood. This is a panel planing and thicknessing machine fitted with a rising and falling table, and a special chain feed gear, the advantage of which is that the feed wheels are driven direct by a strong steel endless chain, and cannot possibly get clogged with the chippings from the machine or come out of gear, whilst the tension and lift of the feeding rollers is not interfered with by any varying thickness of timber, and the driving gear can be placed all on one side of the machine, leaving the opposite side quite free from belts, and allowing plenty of room for manipulating the timber. Messrs. Cunliffe and Croom, of Manchester, are busy on a number of orders for various special tools. They have in hand for the Admiralty a number of drilling machines and cold iron sawing machines capable of sawing mild steel and iron plates up to 6in. in thickness, the top of the table being clear to set work in any direction; also a number of machine tools for producing cotton machinery of high-class work, and they have just completed a plant of machine tools adapted for the economical production of prepayment gas meters, on the "penny-in-the-slot" system, consisting principally of specially-designed automatic milling and drilling machines, and ungeared hand lathes. As a result of investigations which have been carried out for some time past by Mr. John J. Royle, of the Dalham Works, Manchester, with regard to the production of a highly-compressed carbonaceous material as fuel for various heating appliances, he has succeeded in obtaining a smokeless fuel which will probably be a keen competitor with gas and oil, and which, when properly made, burns with great regularity and trustworthyness. This he is now introducing for use in specially designed heating stoves, and a further very useful application is being made in a specially constructed glue-kettle to be heated with this fuel, which is certainly a great improvement upon this class of appliance at present in use. In this kettle the fire-box is so arranged that there is no possibility of the burning fuel coming in contact with anything outside, and the glue kettle can be kept hot for any length of time by simply adding two or three pieces of the fuel from time to time as it burns down. I understand that one of these kettles has been kept boiling for about six hours at a cost of something like one penny, and whilst there was no smoke whatever from the fuel, the boiling of the water was absolutely steady and uniform the whole time.

Only a slow business continues to be reported in the coal trade, with no present indication of any increasing demand except as the approach of the winter season brings forward gradually enlarging requirements for house-fire consumption. All descriptions of fuel for ironmaking, steam, and general manufacturing purposes continue bad to sell, and pits are still only kept going about four days per week with supplies in excess of requirements. With regard to prices, these are not more than maintained for the better qualities, whilst inferior descriptions are rather weak and irregular, slack showing, if anything, a downward tendency. Best Wigan Arley is still quoted 11s. to 11s. 6d., Pemberton four-foot and seconds, Arley, 10s. to 10s. 6d.; common house coals, 8s. to 8s. 6d.; and steam and forge coals, 7s. to 7s. 6d. per ton at the pit mouth, but only in exceptional cases are the maximum figures being got. Engine fuel ranges from 3s. 6d. to 4s. for common slack, to 4s. 6d. to 5s. for good medium sorts, and 5s. 6d. to 6s. for the best qualities at the pit mouth.

Although there is still a fair weight of business being put through in the shipping trade, further buying on Scotch accounts is being carried on very cautiously, and there is not the same firmness as recently in prices, common steam coal, delivered at the High Level, Liverpool, or the Garston Docks, being obtainable about 8s. 6d., with better qualities quoted at 8s. 9d. to 9s. per ton.

Whilst the miners in this district naturally accept the election of Mr. Samuel Woods, M.P., President of the Lancashire and Cheshire Miners' Federation, to the secretaryship of the Parliamentary Committee of the Trades Union Congress, as a sort of compliment to themselves, the election is regarded with still further satisfaction as an important recognition of the efforts which have been put forward to secure the passing of the Eight Hours (Mines) Bill, and the Lancashire and Cheshire Miners' Federation have passed a resolution congratulating their president "On his appointment to the position of secretary to the Parliamentary Committee of the Trades Union Congress, as, on his election to that office, they recognise the hearty co-operation of the different trades unions in their efforts to secure a legal eight hours day for miners."

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE fine weather during the second week in September gave hope of an Indian summer, and consumers of coal, anticipating a warm September and October, held their hands in expectation of lower values. A week of sunshine, however, terminated with the Doncaster Races, and dull cold weather having set in, there is not much probability now of any change taking place until the beginning of October, when the usual winter advance will be made. House coal is in much larger demand, and the output of the district, although unevenly distributed over the various colliery concerns, is large. It becomes increasingly evident that the smaller collieries will have the greatest difficulty to make a profit at present prices, and under existing conditions of working. The large firms have, up to this time, had less difficulty in carrying on their business at a profit, though that is admittedly very lean. With the exception of the trouble amongst the colliery enginemen, which at present is assuming a rather acute and threatening aspect, other disputes with regard to wages are being gradually overcome. In several instances the points of difference have been, by agreement, referred to the Joint Conciliation Board. Several extensions of existing workings are in progress, and from these an increased output will very soon be available. A fair average tonnage is forwarded to the metropolis, but there is no great rush there on the part of householders, and the demand is therefore moderate. Sea-borne fuel from the Northern coalfields, having been largely sent elsewhere during the Scotch strike, is less abundant than usual in the London district. This, of course, helps inland coal, and values are rather firmer than at the corresponding period of last year. Silkstones are from 9s. 6d. to 11s. per ton; Barnsley softs, 8s. to 9s. per ton; other qualities 9d. to 1s. less. These are the quotations at the pits. In steam coal Hull and the other Humber ports continue to take a full average tonnage, there being the usual pressure at this time to complete deliveries to the Northern ports while the markets still remain open. For Barnsley hards 7s. 9d. to 8s. 3d. per ton is quoted, other qualities from 7s. per ton. Gas coal, which is in abundant supply, makes 7s. to 8s. per ton. Manufacturing fuel, the supply of which is in excess of the demand, can be had at 4s. to 5s. per ton, good slack being 2s. 6d. to 3s. 6d. per ton, and smudge, &c., as low as 2s. per ton. Coke is quoted at from 9s. to 11s. per ton, with a moderate demand for Lincolnshire and Northamptonshire.

Manufacturers having a connection with the United States report that business in cutlery and hardware is increasing gradually every week. At the same time there is nothing like the heavy "boom" which was anticipated on the termination of the period of suspense, while the Bill was lingering in the Senate. Several of our largest firms, reluctant to deprive their hands of employment, kept them engaged in making stocks, in the expectation that these would be speedily cleared when all uncertainty was at an end. They have been disappointed in that expectation, the orders which have come in having been light. One or two manufacturers state that they have not been able to clear off one-half of the finished goods they had accumulated. This small demand has been caused largely by the depression of trade in America itself, where the high tariff imposed under the McKinley Act has not had the effect its authors anticipated—viz., to benefit the American cutlery and plate manufacturers. The advices received in Sheffield state that the McKinley Act, instead of fostering the native industries in the goods which are usually obtained from the Sheffield district, has really had an adverse influence. Business is reported all round rather bad in the States, but there are signs of an improvement, and on these becoming more definite Sheffield will participate in the benefit. The cutlery manufacturers in this city have somewhat more work in hand than during the summer months. Novelties, both in the cutlery and the plated trades, chiefly in the latter, are now being got ready for the approaching season. There is more doing in electro-plate and silver goods, in which great progress in the combination of the artistic with the useful has been made in Sheffield of late years. The Japanese and Chinese War is reported to have affected the copper market, causing a rise in the value of that metal, which operates directly upon the makers of electro-plate goods.

It is gratifying to note that the South American markets are beginning to look up. London shippers, through whom most of our Sheffield houses do the bulk of their business, are giving more hopeful accounts of that market. Inquiries are much more numerous than has been the case for several months, and these are not altogether fruitless of work. Although trade with the Argentine Republic can scarcely at present be said to be up to the average, the agents of Sheffield houses report to their principals that before the end of the year an improved state of affairs may be looked for. Within two months the shipment of produce to this and other European countries will then have set in, causing an improvement in the rate of exchange from the other side, and increasing the business over here. The protracted disturbances and financial embarrassments in Argentina have caused merchants out there to limit their orders to pressing requirements. Stocks of hardware and goods are therefore very low, and the beginning of an active demand must inevitably cause large quantities to be sought from England. Better accounts are also being received from the Brazils. A welcome rise in the rate of exchange has taken place during the last fortnight, owing principally to the extensive shipments of coffee and other goods. Several of our manufacturing houses, during the dislocation of business caused by internal trouble, withdrew their travellers from the Brazilian and other South American markets, but these have again resumed their journeys and are reopening business with altogether a much more hopeful prospect. Trade with Spain, on the other hand, is anything but encouraging, several of our houses being exceedingly slack, while the advices sent home are not hopeful of any early change for the better. Business all round in cutlery and hardware goods for the Far East cannot possibly get brisker until the conflict between Japan and China has terminated in some fashion.

Comment has been freely made on the railway traffic returns for August as showing a very large increase compared with the corresponding period of last year. This is no doubt the case, but it seems to have been forgotten that the coal traffic last year was at a standstill owing to the seventeen weeks' stoppage. Not only did the strike entirely paralyse the coal trade, but it also prevented the movement of iron and steel and other goods. The only fair comparison of the traffic returns of August last is to put them side by side with those for August, 1892. The result is to bring out a very considerable falling-off, but the general view in the Sheffield district is that the traffic will increase as trade, particularly in the heavy departments, slowly revives.

The movement in railway material, to which attention was directed a month ago, has not quite been maintained, recent orders having been exclusively for the home companies. It is expected, however, that foreign railways must soon begin to place more work, but there can be no general animation until the great South American markets resume their normal condition. Several of our manufacturers anticipate that the result of the war between Japan and China will be to wake up the Chinese Government to the necessity of a reorganisation of their entire military and naval system. This would not only involve an immense amount of work in military and marine material, but the development of the country, particularly on the Eastern seaboard, in railways, telegraph wires, and other facilities for rapid and effective conveyance of troops and material. If this should be brought about, the effect will be felt far beyond the manufacture of warlike goods, for the abandonment of the old policy of excluding the foreigner and all his works would be inevitably followed by the opening up of markets for European goods in nearly all directions. England would be sure to benefit, with Germany, more than any other country.

The stiffening in the iron and steel industry, to which reference was made last week, still continues. The advance of 2s. to 3s. per ton obtained in the Birmingham iron market, as compared with the quotations of six weeks ago, is an important factor in the situation. Lancashire pig iron has similarly moved upward, and with a perceptible disposition on the part of consumers to do business. Hematites are making from 52s. to 54s. per ton; common forge iron, 39s. to 40s., delivered in Sheffield; Bessemer billets, £5 10s. to £5 15s. per ton.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE end of the Scotch miners' strike having failed to come as speedily as was expected last week, the buying of pig iron in this market has been checked, more especially as the disturbance has extended, some of those who resumed work last week at the old rate of wages, and against the wishes of the Federation, having again come out, and there is likely to be as great a scarcity of fuel as there was before. In that case the Scotch mills, forges, and foundries, which recommenced operations last week, will in many cases have to stop again, and that will affect the consumption of Cleveland pig iron. Large quantities of it have recently been bought by Scotch consumers, and during the past few days there have been heavy deliveries to Grangemouth from the Tees, but these will have to be suspended if adequate supplies of fuel cannot be obtained. Apart from this the trade is better, and a more hopeful tone is generally manifest. A more confident tone is apparent, for consumers are now desirous of buying for delivery over a considerable period, and they would hardly adopt this policy if they had any reason to expect lower prices. Hitherto this year they have confined their purchases to hand-to-mouth requirements, as prospects have been too uncertain to encourage them to speculate. That a larger volume of trade is this half-year being done in the North of England may be judged from the traffic receipts of the North-Eastern Railway, which has practically the monopoly of the carrying trade of the district, because the receipts since July have reached £1,866,909, or £58,548 more than in the corresponding period of last year, which itself was not an unsatisfactory time. Last week's receipts were £154,340, or £5291 above those of the corresponding week last year, and nearly £10,000 more than in the same week of 1892. Somewhat more encouraging reports are given by some of the shipbuilders, and these have not failed to strengthen certain departments of the finished iron and steel trades, as large orders for plates and angles have been given out; and the shares of limited companies enjoyed in the iron and steel industries, notably those of Armstrong-Mitchell, have increased considerably in value, as investors are very desirous of buying them, believing that they will reach higher prices.

The tendency of pig iron quotations is decidedly upwards, and sellers are little affected by the fluctuations in warrants, for these latter are brought about chiefly by the operations of speculators, selling out to take their profits or buying for a further rise. Producers are so well supplied with orders that they can hold out for better rates, and this week they have not been doing business under 36s. 6d. per ton for prompt f.o.b. deliveries of No. 3 Cleveland G.M.B. pig iron, while some who have scarcely any available for sale have been able to get 36s. 9d. and even 37s. Cleveland warrants have been as low as 36s. 3½d. cash, but on Wednesday reached 36s. 4½d. The stock held by Messrs. Connal and Co. on that evening was 89,719 tons, or 670 tons decrease this month. No. 4 Cleveland foundry pig iron has been 35s. 6d., and grey forge has been advanced to 34s. 9d., owing to the large sales that have recently been made to Scotland, and the readiness with which buyers paid 34s. 6d. Relatively these common qualities of pig iron are cheaper than No. 3, as usually there is only a difference of 1s. per ton between that and grey forge. Hematite pig iron is in brisker request, and M. Nos. of local brands have been raised to 43s. 3d., and in some cases to 43s. 6d. per ton for prompt delivery, while 43s. 6d. is regularly asked for deliveries to be made over the next quarter. Shipments of hematite pig have increased to Scotland and the Continent, and local consumption is also larger. Foreign ore improves in price as freights increase, 12s. per ton being quoted and paid for ordinary Rubio delivered Tees. The exports of pig iron from the Tees this month have reached 68,180 tons, as compared with 57,498 tons last month, 77,419 tons in July, 1894, and 74,782 tons in September, 1893, all to 26th. The shipments have increased considerably during the last ten days, owing to the pressure of Scotch consumers' requirements in view of the termination of the strike.

The official returns of Mr. Waterhouse to the Board of Conciliation, showing the deliveries and prices of manufactured iron in the North of England for the two months ended August 31st, may be looked upon as satisfactory, though they differ little from the figures for the previous two months, there being an advance in prices of less than 4d. per ton, and this being so, wages at the mills and forges during October and November will, in accordance with the sliding scale, be the same as have ruled during the last two months. Rails, iron, have fallen 1·51d.; plates, 0·2d.; and bars, 5·4d.; while angles have advanced 0·03d., and the total average 3·92. The decrease of 2787 tons in the deliveries may partly be accounted for by the stoppage of the mills in Teesside for Stockton Races in August. It is noticeable that the production of shipbuilding iron has fallen off, only about 38 per cent. of the iron being in the form of plates, against 41 per cent. in the previous two months, while the proportion of angles fell from 16 per cent. to 12¼ per cent. On the other hand, the deliveries of bars increased, and the proportion went up from 40 per cent. to nearly 48 per cent. The summary of the statistics is interesting, and is as under:—

| Description. | Weight invoiced. Tons. | cwt. | qr. | lb. | Percentage of total. | Average net selling price per ton. £ | s. | d. |
|---|---|---|---|---|---|---|---|---|
| Rails .. | 417 | 12 | 2 | 7 | 1·94 | 4 | 6 | 5·51 |
| Plates .. | 8,179 | 14 | 2 | 5 | 37·89 | 4 | 14 | 7·51 |
| Bars .. | 10,321 | 4 | 3 | 12 | 47·81 | 5 | 1 | 9·72 |
| Angles .. | 2,669 | 5 | 0 | 26 | 12·36 | 4 | 15 | 6·77 |
| | 21,587 | 17 | 0 | 22 | 100·00 | 4 | 18 | 0·22 |

It has been officially ascertained that the average price for steel plates realised by the Consett Iron Co. during the three months ended August 31st differed so little from that of the preceding three months, that in accordance with the sliding scale wages for the next quarter will be the same as those now prevailing at Consett Mills, and other works which regulate their wages by Consett will continue the old rates.

A slight improvement may be reported in the finished iron and steel trades of this district, but to secure the orders manufacturers have had to reduce their quotations, as consumers would not pay the rates which have recently been asked, and which producers expected to get. Their endeavour to raise prices has not been successful. The improvement has been chiefly in steel ship-plates, due to the increased business done by some of the shipbuilders, who have in some cases booked fair orders for new vessels during the last few days from some of the leading shipping companies, who are taking advantage of the low prices to replace vessels that have been lost. One of the shipyards on the Tyne which has practically been idle all this year has recommenced regular operations. Sir Raylton Dixon and Co., Middlesbrough, have booked another order for a steamer of 5500 tons burthen for a continental shipping concern. There have been sales of steel ship plates at less than £4 17s. 6d., less 2½ per cent. at works, but £5, less 2½ per cent. is the regular quotation, while £4 15s., less 2½ per cent., is the figure for steel angles, which are not so readily obtainable, now that the large works of Messrs. Dorman, Long and Co., are closed.

The Darlington Steel and Iron Company's establishment will be altogether closed next week, and now there remain at work only 300 out of the 800 usually employed. At present the company finds it impossible to compete with the firms nearer the seaboard, and the supplies of raw material. The Darlington Company has to pay 2s. per ton carriage for its pig iron, which the Middlesbrough firms escape, and there is the extra carriage to the shipping port of rails that are for export. Heavy steel rails are at £3 12s. 6d. net at works. A good demand is reported for steel billets, chiefly for the tin-plate manufacturers of South Wales, but an increasing trade is done with Manchester *viâ* the Ship Canal; a cargo of 660 tons was sent this week.

Ironfounders are only poorly employed, and prospects have been injuriously affected by the recent lengthy strike. On Tuesday, the North-Eastern Marine Engineering Company, Wallsend-on-Tyne, cast at its foundry one of the largest castings ever made in the North. It is a bed-plate weighing nearly 40 tons for the plate-rolling mills of Messrs. John Spencer and Sons, Newburn Steel Works. Engineers are somewhat better off, but are far from able in most cases to keep their establishments in full operation. Messrs. Ashmore, Benson, Pease, and Co., Stockton, have just completed at Selby the conversion of a large gasholder from a single lift to a telescopic holder, the work being executed within six weeks. Messrs. Furness, Withy, and Co., shipbuilders, West Hartlepool, have commenced the construction at their yard of an extensive graving dock, Mr. Walter Scott, of Newcastle, being the contractor. The locomotive shops are fairly well occupied, but a number of men have been paid off at the North-Eastern Railway's North-road shops, Darlington. Bridge builders have a tolerable amount of work on hand, and prospects are more encouraging.

The Stockton Forge Company, which has secured the contract for the bridges on the new Annfield Plain and Consett line, has just completed the reconstruction of the Wylam bridge over the Tyne. The new superstructure, which has been placed upon the original stone piers, consists of steel plate girders, with a decking of creosoted pitch pine planking 6in. thick, laid at right angles across, and overhanging the main girders, whilst on the upper surface is a substantial layer of tar-concrete paving. The designs are by Messrs. J. Watt, Sandeman, and Moncrieff.

The death took place on Saturday of Mr. George Young Blair, of Stockton, one of the leading marine-engine builders in the North of England, and head of the eminent firm of Blair and Co., marine engineers. Mr. Blair, who was sixty-eight years of age, has been suffering from heart disease for some years, but was only confined to his house for the last five weeks. Mr. Blair was a native of Drumranck, in the Dundee district, and early devoted himself to engineering pursuits, especially in the marine departments. After gaining experience in Scotland and Lancashire, he became manager of the engineering department of the Jarrow Works of C. M. Palmer and Co.—now Palmers' Shipbuilding and Iron Company. In 1855 he left Jarrow to assume the managership of Messrs. Fossick and Hackworth's engineering works at Stockton, and on Mr. Hackworth's leaving it in June, 1864, the name of the firm was changed to Fossick, Blair, and Co., Limited. Shortly afterwards Mr. Blair became the head of the concern, and the name was changed to Blair and Co., Limited, under which designation it has since been carried on. The works employ 2500 hands and cover fourteen acres of ground. Mr. Blair was highly respected in commercial circles, and greatly beloved by his workmen.

The members of the Boilermakers' and Iron Shipbuilders' Association on the North-East Coast have determined to oppose an agreement which has been made between the Employers' Association and their own society. This agreement deals with wages disputes and new machinery introduced by the employers, and affects only the North-East Coast. Though their Association, as a whole, approves the agreement, the local members do not, and they have held a meeting and passed a strong resolution demanding the suspension of the agreement, which resolution they have sent to the Council. This is the first time the members in this district have ever met in conference in opposition to the executive.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

The Glasgow pig iron market has been comparatively inactive this week. The uncertainty which exists with reference to the termination of the miners' strike has almost put an end to speculative business for the time. Transactions have been, for the most part, of a jobbing description, and confined to Scotch warrants, scarcely anything being done either in Cleveland or hematite iron. Prices are 3d. to 4d. per ton lower than a week ago, Scotch warrants being done at 43s. 5d. to 43s. 5½d. cash.

The values of makers' special brands are somewhat irregular, while Summerlee No. 1 has declined 1s. 6d., and No. 3 6d.; Glengarnock No. 1, and Dalmellington Nos. 1 and 3, are 6d. higher. The prices are as follows:—G.M.B. f.o.b. at Glasgow, No. 1, 45s.; No. 3, 43s. 6d.; Monkland, No. 1, 48s.; No. 3, 44s.; Carnbroe, No. 1, 48s.; No. 3, 46s. 6d.; Summerlee, No. 1, 57s.; No. 3, 51s. 6d.; Calder, No. 1, 59s.; No. 3, 50s. 6d.; Coltness, No. 1, 59s.; No. 3, 52s.; Glengarnock at Ardrossan, No. 1, 54s. 6d.; No. 3, 49s. 6d.; Eglinton, No. 1, 54s. 6d.; No. 3, 48s.; Dalmellington at Ayr, No. 1, 50s. 6d.; No. 3, 49s. 6d.; Shotts at Leith, No. 1, 59s. 6d.; No. 3, 52s.

The output of pig iron consists of the produce of three furnaces making ordinary pigs at Coltness, an additional furnace having been lighted there since last week. No arrangements are yet completed for restarting the furnaces, but as soon as the miners are back to work in large numbers, the lighting of the furnaces will proceed. Weeks must pass, however, before iron is made in the usual quantities. Some think that on this account the market is likely to become firmer, while others are of opinion that the lighting of the furnaces will be the signal for a drop in prices.

There is a slight improvement in the pig iron shipments, which are still, however, comparatively small, the figures being 3569 tons, against 3231 in the corresponding week. There was despatched to Holland 835 tons, Belgium 550, Canada 355, Germany 320, India 20, Australia 285, France 28, Spain 60, China and Japan 200, other countries 206, the coastwise shipments being 700, against 946 the same week of 1893.

Little can be said as yet with reference to the finished iron and steel trades. A beginning was made with the manufactured at several of the works a fortnight ago; but it was impossible to continue regularly, owing to the intermittent supply of coals. There is now a prospect, however, of a commencement being made in earnest.

The prices being quoted for mild steel are now lower than those fourteen weeks ago, previous to the strike. Ship plates have declined 5s., and angles 2s. 6d. per ton.

There was shipped from Glasgow in the past week locomotives worth £5000, sewing machines £4400, other machinery £8360, steel goods £2752, and miscellaneous iron goods £16,123.

Some interest is shown by pipe founders in the contract which is about to be arranged for cast iron pipes for Preston.

The coal trade still consists almost entirely of imports. The whole of the shipments for the past week reached only 9622 tons, against 230,381 in the corresponding week, and the total shipments for the year to date now show a decrease of 1,498,570 tons. There is a contract in the market consisting of from eight to a dozen cargoes for the Danish State Railways. Whether our coalmasters will go in for this or not seems to be a little doubtful, although the prospect of steady labour being secured in the Slamannan district, from which such coals are usually drawn, is now more hopeful.

The strike of miners is now in its fourteenth week, and great efforts are being made by the leaders to keep the men out. Picketing has been carried on incessantly day after day, and in Lanarkshire, particularly, something like a reign of terror has prevailed for weeks. Occasionally excited mobs of miners have had to be dispersed by the police and military. The authorities have shown great forbearance—some are inclined to think rather too much. Picketing has been organised by the leaders under the eyes of the police, and there can be no doubt that intimidation has prevailed very generally throughout the mining districts. In spite of this, many hundreds of men go to work in different localities, eluding the pickets in such a way as to show that they have no desire to continue the struggle. There is no prospect whatever of any concession on the part of employers.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

The "ukase" of the colliers' representatives, that each colliery should ballot for or against the sliding scale, has been brought practically to a finish, and the "noes" have it in overwhelming numbers. In national questions which have led up to hostilities, the smaller the cause the graver the results, and here the objection to take a checkweigher's evidence by the Coalowners' Joint Sliding Scale Association promises to destroy the scale. The prevailing opinion is that the scale has come to an end; but I have hopes that during the ensuing six months' notice common-sense views will predominate, and amicable arrangements will prevail and preserve the broad principle of the scale. Probably some wise amendments may be suggested and adopted.

At present the Welsh collier has very little reason for complaint. The demand for coal is well maintained, and prices are good. Last week there was an unusually heavy shipment at the Cardiff ports, no less than 315,000 tons, and I hear that in several instances coalowners found a difficulty in completing orders. Best steam has touched 12s. Latest quotations on 'Change, Cardiff, are:—11s. 6d. to 12s.; seconds, 11s. to 11s. 3d.; dry sorts, 10s. to 10s. 3d.; best Monmouthshire, 10s. 6d. to 10s. 9d.; seconds, 9s. to 9s. 9d.; small, 5s. 3d. to 5s. 9d.; f.o.b. House coal keeps up well, and at present quotations it has been difficult to get orders booked forward, showing that higher prices are in view. Latest Cardiff prices are:—Best households, 11s.; No. 3 Rhondda, 10s. 3d. to 10s. 6d.; brush, 8s. 6d.; small, 6s. 6d.; No. 2 Rhondda, 8s. 9d.; through, 7s.; small, 5s.

As invariably happens when coal prices are up, other industries are in harmony. Pitwood commands 15s. 9d.; patent fuel, 11s. to 11s. 6d., and coke is firm at 15s. to 16s.; furnace, 17s. to 17s. 6d.; foundry and special foundry, 20s. to 21s.

Swansea, similarly with Cardiff and Newport, is in the enjoyment of a robust coal trade. Last week the shipment of coal and patent fuel largely exceeded the average, totalling over 50,000 tons. The Port trade in all respects was brisk, exceeding by 18,000 tons that of the corresponding week last year, and by 5000 tons the totals of the preceding week. Some of the coal items are suggestive. France 13,183 tons, Spain 663, Sweden 650, Denmark 2660, Germany 500, Italy 3222, Tunis 640, Buenos Ayres 670, Rio de Janeiro 1210, Montreal 3296, San Francisco 3000, United States 2222, home ports 9418.

In patent fuel France took 2000 tons; Spain, 2200; Italy, 5870; Tunis, 112 tons.

I shall not be surprised to see a steady advance in the demand for patent fuel both at Cardiff and Swansea, where the make is of exceptionally good quality. The knowledge is spreading that while small and large coal lose a percentage of value by weather exposure, patent fuel escapes. Swansea quotation is 10s. 6d. to 11s. 6d.; coke—furnace, 12s. to 12s. 6d.; foundry, 17s. 6d. to 18s. Iron ore—Tafna, 11s.; Rubio, 11s. 3d. to 12s.; Pitwood, 16s. 6d. to 16s. 9d.

I am glad to be able to record more buoyancy in the steel trade. The requirements of the Great Western, local railways, and increased sidings, and colliery requirements for light sections, with a better demand foreign, has given more animation to the rail trade, and the steel bar trade is certainly benefiting from the increased activity in the tin-plate trades of the West of Wales and of the Newport district. At length this trade appears to have really turned the corner, and prospects are every week becoming brighter. The total shipment last week from Swansea was 113,408 boxes, or 90,000 boxes—so reported on 'Change—more than in the corresponding week of last year. If with this is coupled the fact that the quantity brought from works last week was only 57,793 boxes, it is tolerably clear that the stocks will not long last the influence of the reduced tariff. The stock in warehouses and vans is now down to 282,505 boxes, so an improvement in price may be regarded as close at hand.

Swansea Exchange quotations, iron, steel, and tin-plate, this week are as follows:—Glasgow pig, 43s. 4½d.; Middlesbrough, 36s. 3d. prompt; hematite, 43s. 1d.; Welsh bars, £5 to £5 2s. 6d.; angles at usual extras, f.o.t. at works; steel rails, heavy, £3 15s. to £3 17s. 6d.; light, £4 10s. to £4 15s. f.o.t.; sleepers, channels, &c., according to section and specification; steel sheets, £6 5s. to £6 10s., with the usual extras for the higher gauges; sheet iron, £6 to £6 10s.; Bessemer steel, tin-plate bars, £4 to £4 2s. 6d.; Siemens best, £4 2s. 6d. to £4 5s.; all delivered in the district, cash less 2½.

Tin-plates, makers' last quotations:—Bessemer steel cokes, 10s. 6d. to 10s. 9d.; Siemens coke finish, 10s. 9d. to 11s.; best charcoal, 12s. to 12s. 6d., according to finish; ternes, per double box, 28 × 20 c., 20s. to 24s.; wasters, 6d. to 1s. less than primes; odd sizes, usual extras; all delivered in Prince of Wales Dock, Swansea, cash less 3 and 1 per cent. Block tin has receded slightly, and now is £71 7s. 6d. to £71 10s. Lead, English up to £10 1s. 3d.; Spanish to £9 17s. 6d.

The tin-plate trade with Russia is improving rapidly, and the clearances for the United States this week up to my despatch were close upon 5000 tons. Iron ore is coming in pretty freely to all the large works.

Notice of a restart of the Blaina Iron and Tin-plate Company has appeared. It will date from the 15th October. A contemporary states that inquiries amongst the workmen are to the effect that they will take no action until it is ascertained under what conditions the neighbouring works owned by Capt. Phillips will be carried on on and after September. It is stated that since the resumption of work the workmen have given a concession of fifteen sheets per box. The meeting of the Abertillery and Nantyglo men held of late appear to suggest that their concessions will cease, but upon this head possibly the intention will be altered. Some doubts also prevail with regard to the Pontymister and Waterloo workmen. Treforest has been restarted on the old lines. A satisfactory condition prevails at Briton Ferry. Taking a survey of the whole of the district, there is reason to hope that there will be no labour upset in the event of improved times and prices.

The result of the ballot at the Albion Colliery, for and against the scale, has been as follows:—For giving notice to end the scale, 910; against, 232. Work is being carried on with a considerable degree of vigour since the explosion.

The appeal to the public has met with a generous response. The Central Fund acknowledges over £13,000, the Mayor of Cardiff over £9000, and the *Western Mail* and *South Wales News* funds total up over £3000.

A good deal of discussion prevails in the district regarding explosives, and it seems almost certain that in dry and fiery mines gunpowder will be disused and cordite or other explosives used instead. Several of the conditions prevailing before great explosions are constantly met with; driving ahead day and night to meet the demand for coal, sudden barometrical changes, blasting. Fortunately the colliery management is thoroughly on the alert, and the keenest vigilance is being used. On the part of the men, too, I am pleased in not having had of late to record any gross irregularities or rashness.

An exceptional case against tin-plate workmen was heard at the Swansea police-court on Saturday. Twelve men of the Fox Hole Works were charged with breach of agreement with their employers. They had agreed to a certain reduction, and upon the strength of this the company entered into contracts to buy and sell metal; but the defendants refused to abide by the terms of the agreement, and serious losses resulted. They were fined according to damage from £4 to £10 each.

The Vale of Glamorgan Railway is well in hand. Messrs. Pethick Brothers are the main contractors, and the preliminary work at Barry is nearly completed prior to the excavation of the large tunnel at Porthkerry. Mr. Woolley, of Wrexham, has entered into a contract to make eight miles of the line on the Bridgend side.

An inquiry before Sir George Nares, regarding an application by the Barry Dock Company to construct an embankment or breakwater, has been adjourned, to enable Sir George Nares to see the effect of the south-westerly gales upon the small craft in the harbour.

The Cambrian Miners' Society at their last meeting condemned the continuance in the district of the double-shift system.

The Atlantic greyhounds, as the Campania and others are called, are stated to use 600 tons a day when going at their fullest speed.

Steamers of 3000 and 4000 tonnage have been plentiful in Cardiff during the week, and several instances have occurred of 2000 tons of iron ore coming in.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

Only a slow inquiry for either raw or manufactured iron has been reported upon the week, and prices are rather irregular. The chief iron-using industries have so far shown no sufficiently increased activity to represent any established material improvement. New work certainly has been coming forward more freely in some departments, and in many cases engineering establishments have been getting busier since the beginning of this quarter, but the present state of the iron industry, taking it all through, is still anything but one of activity, a number of works only running short time, while the best that can be said is that business is likely to slowly improve. Another unsatisfactory feature is that the different branches of the manufactured iron trade continue in a more or less depressed condition, and until there is some really substantial improvement in that direction, the prices for raw material can hardly be expected to advance. On the other hand the general absence of stocks and the improbability of lessened cost of production operate as a check on any downward move in the market, and it is therefore scarcely probable that quotations of pig iron will recede to any material extent.

Only a moderate activity exists in the iron and steel trades of Silesia, pig iron meeting with limited request, while malleable iron has been in tolerably good call. Bars, for instance, are well inquired for at M. 120 p.t., free at works, and M. 125 p.t., free Breslau, and there have been some fair orders coming in from abroad. Plates, too, have been in fair request, while for girders only a weak demand is experienced. Business on the Austro-Hungarian iron market remains quiet, and but few contracts have been booked lately. One fact is apparent, that buyers are not going in for quantities. Small parcels only are bought at short terms of delivery. Bars and girders are in regular demand, and plates have been quite actively inquired for. A decidedly increasing demand is to be noted in English foundry pig. The business in hardware is rather lively, especially in the Hungarian market. Official quotations show no alteration generally both for raw and finished iron.

There is little of interest to note in connection with the French iron business. Buyers have been slow in placing orders, and there is some weakness noticeable in prices; the only branch with life in it is the bar trade. Heavy rails in steel are also in tolerably good request at 160f. p.t.; steel bars fetch about 130 to 140f. p.t., free at works.

On the Belgian iron market the demand for the different sorts of iron and steel continues exceedingly quiet, and the transactions noted during the past week are of small account. With regard to export trade, there has been a better tone reported lately, at least so far as steel manufactured goods are concerned. Prices, if anything, are perhaps a trifle more firm, or rather less inclined to give way than they were a short time ago.

There is very little of a novel character to report with reference to the Rhenish-Westphalian iron trade. Buyers maintain a reserved position generally. Small lots for immediate delivery are being purchased with considerable regularity. Stocks have in some instances decreased. The restriction in the output of pig iron begins to be felt in the iron ore trade, and a certain weakness in demand is complained of; for the present a change in prices has not taken place, but it is not at all unlikely that quotations will become easier. The position of the pig iron business is still the reverse of satisfactory. There has been no improvement in the export demand, and the orders that have been coming in on home account are not sufficient to keep the works in full employment, and there is consequently a feeling of uncertainty, and even distrust, noticeable in some quarters. On the malleable iron market demand and sale have continued fairly good, while prices are inclined to give way a little when there is an order of even moderate weight in question. This is specially the case in bars. Hoops and girders are remarkably quiet. Heavy plates are satisfactorily inquired for, and the mills continue in good activity. Quotations remain the weak point, as usual, and there is little prospect now that a change for the better will set in before the year ends. Sheets are in a similar condition. Steel makers have been doing only a small trade, rails being in poor request generally. The construction shops have also been but moderately engaged for some time past, and prices are exceedingly low. Up to date, a regular activity is maintained at the wagon shops.

Belgian Goods Brake Van.—M. Léon Bika writes to us from Brussels, pointing out an omission in our description of the brake van for the Belgian State Railways, on page 249. The object of connecting the two springs on one side of the van is that the vehicle should be suspended on three points. Our description should have read:—"The two springs, on one side only, are connected by a balance beam;" but the words, "on one side only," were accidentally omitted.

## AMERICAN NOTES.

*(From our own Correspondent.)*

New York, September 20th.

American manufacturers are promptly making whatever reductions are necessary to protect themselves against competing imported products. Home makers are in control of the cotton tie trade, and a 22½ per cent. reduction has just been made in glass to offset the difference of 16 per cent. made by the new tariff list. All necessary reductions will be promptly made. The workmen appreciate the situation and accept the reductions philosophically. A proposition has been made to reduce wages of tin-plate workers 25 per cent. to offset the reductions in duty. A big reduction will be accepted. The real contest has only opened. Wages are declining, but this loss is partly offset at least by cheaper cost of living.

The iron trade is rather quiet. Prices are in some instances quotably lower. Pig iron sales are large; but production has been expanded to 160,000 tons per week, against 85,000 tons twelve weeks ago. Throughout the West demand for mill products is improving, but until railway construction is resumed on a scale of 5000 miles per year there can be no decided improvement in the steel industry of America.

## LONG-DISTANCE TRANSMISSION OF POWER.[*]

By E. Arnold.

In this article the author discusses the influence of the static charge in long-distance power lines, and gives the results of a series of experiments carried out with the three-phase transmission plant between Hochfelden and Oerlikon, in Switzerland. The distance of transmission is 14½ miles, and the plant is of similar construction to that used for the Lauffen-Frankfurt transmission, where the static induction has never given rise to any difficulties even with the most varying atmospheric conditions. The generators at Hochfelden deliver 300-horse power at 50 volts and 3 × 1400 ampères. The current is transformed up by three-phase transformers, having a ratio of 1 : 154·6. The line consists of four wires of 16 0 mm. diameter, run on poles 25ft. high, and at an average distance of 17·7in. from each other. In order to determine the influence of the static charge the delivery ends of the line were disconnected, and the generators were run both with variable speed and constant pressure, and with constant speed and variable pressure. The frequency was varied from 49·3 to 21·6, and tables are given showing the low-pressure and high-pressure currents under these varying conditions. Generally speaking, when the frequency is constant the secondary or high-pressure current, which in this case is entirely due to the electro-static capacity of the line, rises with the pressure, whilst at constant pressure it rises as the frequency is increased. The same tests were repeated when the line was entirely disconnected, and the results are shown plotted in curves, from which it is seen that the primary current, both for the line connected and disconnected, is directly proportional to the pressure. One diagram is given which shows that the curve of primary current when the line is disconnected intersects the corresponding curve when the line is connected, from which the author concludes that the capacity of the line tends to diminish the primary current at the generating station, and in certain cases acually does so. This point he then investigates theoretically, and he finds that by the addition of self-induction to the line it is always possible to so balance the effect of capacity as to work without any phase-difference between current and electro-motive force.

The practical conclusion of this investigation is that the capacity of the line need never interfere with the proper working of a long-distance transmission plant.

Launch.—On the 18th, the s.s. Torbryan, 178ft. by 28ft. by 14ft. 2½in. moulded, built by Messrs. R. Craggs and Sons, of Middlesbrough, was taken out for loaded trial with satisfactory results. Engines, 14in., 22½in., 37in., by 27in., by Messrs. Westgarth, English, and Company, of Middlesbrough. This, we are informed, is the third vessel built by the same firms for the owners, Messrs. Whiteway and Ball, of Torquay.

New Works at Salonica.—It appears that the acceptance of the tender of a Belgian firm of contractors for the construction of the new marine works in connection with the port and harbour of Salonica has not been unattended without unsatisfactory circumstances. The French society for the working of Eastern railways has protested against the award on the grounds that by the terms of its contract with the Turkish Government it is entitled to the preference in all engineering works of this or of a similar description. It remains to be seen what conditions are attached to the same contract, for an absolutely unconditional agreement would be a somewhat unusual circumstance, even for the Government of the Ottoman empire.

Naval Engineer Appointments.—The following appointments have been made at the Admiralty:—Engineer: Ernest F. Sparkes, to the Buzzard, in lieu of a chief engineer, to date September 22nd; George L. R. Perkins, to the Bullfrog, to date September 25th; George H. Morris, to Victoria and Albert, to date September 24th. Assistant-engineer: W. F. Montgomery—temporarily—to the Buzzard, to date September 22nd; Lewis J. Watson, Henry C. Anstey, G. W. Baldwin, and Samuel P. Ferguson, to the President, additional, for Royal Naval College, to date September 29th. Probationary assistant-engineers: James Maxwell, Charles G. Ware, John Thompson, Henry F. Bell, Percival C. W. Howe, Charles A. Hardinge, Henry J. Loveridge, Walter Stokes, Henry F. Smith, Edward P. Soper, James T. C. Butland, Gilbert H. Page, William B. Hall, Francis J. Charlton, and Percy Stocker, to the President, additional, for Royal Naval College, to date September 29th.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

⁂ When patents have been "communicated" the name and address of the communicating party are printed in italics.

*13th September*, 1894.

17,395. Gas Washer, G. Pettigrew, Middlesbrough-on-Tees.
17,396. Soap, M. Evans, Wavertree.
17,397. Packing for Stuffing-boxes, A. G. Brown, Liverpool.
17,398. Steam Hauling Machinery, H. C. Lobnitz, Glasgow.
17,399. Steam Pumps, H. C. Lobnitz, Glasgow.
17,400. Aerial Signs, G. A. Baker, Gloucester.
17,401. Apparatus for Aerating Liquids, R. W. Stuart, London.
17,402. Food Preserver and Refrigerator, R. W. Stuart, London.
17,403. Manufacture of Bricks, B. Cochrane, Newcastle-on-Tyne.
17,404. Pistons for Steam Engines, &c., G. Finney, London.
17,405. Measuring Helical Surfaces, W. C. Carter, London.
17,406. Coal-boxes, F. W. Vernon and J. Blackham, Birmingham
17,407. Boot-nailing Machines, W. H. Dorman, Stafford.
17,408. Protecting Plaster Casts, J. V. and A. Hibbert, Preston.
17,409. Taps, J. Mallol, Birmingham.
17,410. Preventing Bicycles Slipping, E. Cusack, Clontarf.
17,411. Chain, W. H. Bailey, J. H. Brindle, A. T. Newbold, and J. Mason, Manchester.
17,412. Hose Boards, G. Tilley, Leicester.
17,413. Kaleidoscopic Toy, H. J. Hayes and C. B. Clarke, Norwich
17,414. Holding Cords, Ropes, &c., J. S. Orton, Birmingham.
,415. Manufacture of Cut Nails, &c., C. March, 17Glasgow.
17,416. Keys for Securing Rails to Chairs, R. Frame, London.
17,417. Fire-lighter or Kindler, A. Drennan, Glasgow.
17,418. Letter-copying Books, W. Howard, South Benfleet.
17,419. Bushes and Bearings for Axles, J. and C. A. Baker, Grimsby.
17,420. Postal Boxes, R. A. Casson, Birmingham.
17,421. Hubs of Velocipede Wheels, J. T. Robson, London.
17,422. Shoe Lasting Machines, W. R. Mudd and A. N. Mawbey, London.
17,423. Music Stools, J. W. Deans and A. M. Foster, London.
17,424. An Attachment to Bottles, F. T. Mott, London.
17,425. Photosculpture, H. H. H. Cameron, London.
17,426. Bow Nut for Instrument Bows, W. Needham, London.
17,427. Hinges and Fasteners for Doors, H. A. C. Foot, London.
17,428. Shears, W. Clark, London.
17,429. Folding Umbrellas, Tents, &c., E. R. Kesterton, London.
17,430. Secretary Drawers, T. Potter, London.
17,431. Coin-freed Gas Meters, G. P. Wadsworth, London.
17,432. Water-closets, W. Cliff.—*(The J. L. Mott Ironworks Company, United States.)*
17,433. Oil Cooking Stoves, E. Rippingille and W. Porter, London.
17,434. Motor, F. Hraba, London.
17,435. Shin or Leg Guards, &c., J. H. Haywood, London.
17,436. Fasteners for Boots and Shoes, R. Gough, London.
17,437. Door Fastener, C. H. Cload and W. H. Mardon, jun., London.
17,438. Self-acting Copying Books, C. J. Davison, London.
17,439. Cycles, J. D. Derry, London.
17,440. Fixing Broom or Brush Handles, J. Burnett, London.
17,441. Bats and Racquets, G. H. Webb and H. M. Walker, London.
17,442. Soldering Metal Boxes, J. Gersant and A. G. Buttifant, London.
17,443. Pivoted or Swinging Mirrors, M. Gillespie, London.
17,444. Busks, G. Carcaut, London.
17,445. Electro-magnetic Friction Clutch, W. C. Bersey, London.
17,446. Plug for Tobacco Pipes, E. M. Richford, London.
17,447. Electrically Propelled Vehicles, W. C. Bersey, London.
17,448. Stoves for Gas, Oil, &c., P. R. Poore, London.
17,449. Lamps for Burning Oil or Spirit, A. Kiesow, London.
17,450. Watch Pockets, S. Glasgo, London.
17,451. Melting Snow, P. R. J. Willis.—*(C. F. Springfiels, United States.)*
17,452. Detaching Block or Hook, G. W. Moore, London.
17,453. Brake Apparatus for Trains, C. Luyers, London.
17,454. Cycles and Velocipedes, P. H. Pritchett, London.
17,455. Charging Gas Purifiers with Lime, H. Gardener.—*(F. D. Marshall, Denmark.)*
17,456. Paper Chamber Vessels, A. R. Newnham, Boscombe.
17,457. Tires for Vehicles, T. T. Roe and F. Parr, London.

*14th September*, 1894.

17,458. Self-starter for Gas Engines, J. A. Ewins, Birmingham.
17,459. Self-driving Motor, A. Blattner, London.
17,460. Lamp Automatic Extinguisher, W. Richardson and W. Jackson, Birmingham.
17,461. Valve for Syphon Cisterns, H. C. Willings, London.
17,462. Furnace Tubes of Steam Generators, W. M. C. Howatson, Perthshire.
17,463. Process for Treating Meat, D. Cook, Surrey.
17,464. Securing Breast Pins, W. Gaskell, Nottingham.
17,465. Working the Points of Tramways, T. Albin, Glasgow.
17,466. Letter Copying Pad Damping Machine, P. Burt, Glasgow.
17,467. Flushing Cisterns for Water-closets, J. Fagan, Keighley.
17,468. Fishing Rods, W. Quine, jun., Isle of Man.
17,469. Advertising, L. Koffman, Manchester.
17,470. Chaff Cutters, T. Sabine, Derby.
17,471. Seats, H. T. Wells, London.
17,472. Mud Guards for Cycles, S. R. Ramsbottom and H. J. Rofe, Manchester.
17,473. Ships' Deck House Lights, J. Shaw, Northumberland.
17,474. Keyholes of Night Latches, A. R. Tonks, Staffordshire.
17,475. Mouthpiece for Tobacco Pipes, T. Legat, Motherwell.
17,476. Machines for Pressing Hay, J. E. S. Perkins, Peterborough.
17,477. Printing Fabrics, W. Pickup and W. Knowles, Manchester.
17,478. Regulating the Feed of Textile Fibre to Openers, &c., T. R. Marsden, Manchester.
17,479. Distribution of Sanitary Fluids, C. E. Macnamara, London.
17,480. Glazing Bars for Windows, P. Y. Lyle, Glasgow.
17,481. System of Cutting Dresses, &c., R. Fox, Glasgow.
17,482. Ring Adjuster, A. E. Lay, London.
17,483. Trunk and other Lock Fastenings, A. J. Bates, Wolverhampton.
17,484 Manufacturing Artificial Fuel, E. Kirbis, Berlin.
17,485. Reversible Safety Stirrup, B. E. T. Cope, Walsall.
17,486. Composition for Preserving Wood, J. Matthews, London.
17,487. Paint Spraying Appliances, G. Skinner, London.
17,488. Connecting Metal Tubes, A. Girbes and P. Foucher, London.
17,489. Rotary Motors, A. Chauveau and L. Guichard, London.
17,490. Railway Chairs and Sleepers, A. E. Muirhead, Glasgow.
17,491. Making Gas, G. Rose, Bishopbriggs.
17,492. Machinery for Cutting Biscuits, G. S. and J. A. Baker, London.
17,493. Machinery for Preparing Cotton, F. Topp, London.
17,494. Trouser Clips, S. Smith, London.
17,495. Boots and Shoes, S. Goodacre and A. F. Sharman, London.
17,496. Line or Cord Fastener, J. J. and T. I. Day, London.
17,497. Filling Lamp Reservoirs, T. E. Phillips and F. C. Chirm, London.
17,498. Alarm Clocks, E. Benest, London.
17,499. Chimney Cowls, F. C. Woodford, London.
17,500. Lamp Shade Holder, A. G. Pretious, London.
17,501. Pipe Mount Appliances, J. Cheshire, Birmingham.
17,502. Electric Time-signalling System, P. R. J. Willis.—*(W. A. Purcell, United States.)*
17,503. Feed Roll for Planing Machines, J. de Sigler, London.
17,504. Tires for Travelling Wheels, A. A. Crozier, London.
17,505. Mud-guard for Cycles, H. G. Payne, Sussex.
17,506. Tongueless Buckle, J. Schwarz London.
17,507. Cycle Frames, C. W. Brown, London.
17,508. Wheat-drying Machines, J. Higginbottom, Liverpool.
17,509. Tricycles, &c., H. Wadsworth, Manchester.
17,510. Electro-depositing Apparatus, H. Le R. Bridgman, London.
17,511. Mills for Grinding, &c., Colour, E. Bush, London.
17,512. Felloes and Tires of Wheels, H. T. Stephens, London.
17,513. Syrens, I. and S. Smith, London.
17,514. Horse-bin, E. S. Colchester, London.
17,515. Postage Stamps, H. R. Winkelmann and P. Sattelkau, London.
17,516. Pneumatic Wheels, F. King, London.
17,517. Type-composing Machine, A. E. Vorreiter and E. Müllendorff, London.
17,518. Stuffing-boxes, T. B. Lightfoot.—*(Gesellschaft für Nindes Eismaschinen, Germany.)*
17,519. Horseshoes, W. and S. Maddock and F. S. Perkins, London.
17,520. Hydraulic Riveting Machines, H. Berry, London.
17,521. Hydraulic and other Valves, H. Berry, London.
17,522. Mortice Bolts, W. A. E. Crombie and the Paragon Bolt Syndicate, Ld., London.
17,523. Clip for Securing Boot Laces, W. H. Thrift, London.
17,524. Hydraulic Lifts and Cranes, G. Andrews, London.
17,525. Laying Electric Conductors, J. A. Jeckell, London.
17,526. Utilising Waste or Excess Heat, L. Jacquin, London.
17,527. Sporting and other Ammunition, W. Hope, London.
17,528. Link-belts, E. F. Sargeant, London.
17,529. Telephone Transmitters, F. H. W. Higgins, London.
17,530. Button-holes, A. Reikmann.—*(The Heaton Peninsular Button Fastener Company, United States.)*
17,531. Shearing Machines, E. T. Hughes.—*(H. S. Daggett, United States.)*
17,532. Fastenings for Hats, C. E. Fonblanque, London.
17,533. Shuffling Playing Cards, C. V. V. Childs, London.
17,534. Pencils, S. W. Pedley, London.
17,535. Devices for Exhibiting Umbrellas, A. Steer, London.
17,536. Fountain Pens, I. Golwer, London.
17,537. Pumps, G. F. Harvey, London.
17,538. Wheels having Pneumatic Tires, J. Elsden, London.
17,539. Connecting Gun Locking Lumps, C. G. Haenel, London.
17,540. Construction of Perambulators, L. Debefve-Moyano, London.
17,541. Lock, C. Smith.—*(J. M. Mushet and N. G. de B. Priestley, India).*
17,542. Lining of Electric Batteries, J. E. Liardet, London.
17,543. Washing Fibrous Material, J. C. Walker, Bradford.
17,544. Destroying or Removing Paints, E. Tessen, London.

*15th September*, 1894.

17,545. Safety Collar Stud, H. F. Schwarz, London.
17,546. Fastenings for Baskets, &c., T. Tilford, London.
17,547. Smoke Bells for Lamps, W. and S. Jones, Stockport.
17,548. Treating and Aerating Milk, J. Gray, Glasgow.
17,549. Internal Combustion Engines, P. Maccallum, Dumbartonshire.
17,550. Cardboard and other Reels, W. Dickinson, jun., Manchester.
17,551. Wheels, W. Haslewood and J. Hazlewood, jun., Birmingham.
17,552. Driving Tandem Bicycles, A. T. Austin, Birmingham.
17,553. Ventilators for Railway Carriages, P. J. Wilson and W. R. Wright, Sheffield.
17,554. Apparatus for Teaching Arithmetic, J. S. Towers, Southsea.
17,555. Making Gas from Coal, H. R. Dinsmore, Liverpool.
17,556. Manufacture of Sodium Biborate, J. Ascough, Birmingham.
17,557. Lubricating Cans, E. Atherton, Brinscall, near Chorley.
17,558. Stable and Out-door Lamps, J. H. Fergusson, Dumfries.
17,559. Fence Standards, R. Howie, Glasgow.
17,560. Price Ticket for Shop Use, J. Wilson, Glasgow.
17,561. Hydraulic Falling Weir Shutter, R. G. Kennedy, Fife, N.B.
17,562. Ventilating Railway Carriages, J. H. Brierley, Halifax.
17,563. Paper for Memorandum Purposes, H. Thompson and A. Catley, Birmingham.
17,564. Clip for Holding the Legs of Trousers, H. Terry and Sons, Redditch.
17,565. Endless Cigarette-making Machines, H. Korte, Germany.
17,566. Electrodes, W. Schäfer and A. Heinemann, London.
17,567. Children's Swings and See-saws, F. A. Wallis, Basingstoke.
17,568. Portable Trouser Stretcher, J. Kiddle, London.
17,569. Apparatus for Receiving Ashes, R. E. Holt, Manchester.
17,570 Affixing Lamps to Cycles, A. Davey, Manchester.
17,571. Mechanism for Water-closets, D. D. White, London.
17,572. Electrical Switches, &c., H. G. Keeble, London.
17,573. Vents, H. Hatton and T. W. and G. Nayler, London.
17,574. Pneumatic Tires, R. R. Gubbins, London.
17,575. Power Indicator for Engines, W G. and C. W. G. Little, London.
17,576. Organs, J. J. Walker and J. Cowling, London.
17,577. Blasting Cartridges, G. Trench, London.
17,578. Small-arms, H. W. Holland and T. Woodward, London.
17,579. Manufacture of Flower-pots, T. Harvey, London.
17,580. Game Apparatus, G. H. Webb, London.
17,581. Collar Studs, W. J. Bax, London.
17,582. Cleaning Tobacco Pipes, P. G. Lewis, London.
17,583. Harness Hames, J. R. Walcock London.
17,584. Skates, H. Kemper, London.
17,585. Engaging Devices for Ropes, A. W. Lewin, London.
17,586. Lighting, &c., Street Lamps, W A. Hunter, Liverpool.
17,587. Hydrocarbon, &c., Burners, J. Watts, Liverpool.
17,588. Cables for Electrolytic Purposes, J. Leith, Liverpool.
17,589. Bearings for Shafts and Axles, N. Roussello, London.
17,590. Plant Fumigating Apparatus, J. Watkins, London.
17,591. Curling Tongs, R. Friedel, London.
17,592. Ferrotype Photographs, H. J. Haddan.—*(R. Aramburu, Spain.)*
17,593. Pumping Liquids, T. T. Best, S. A. Hollingsworth, and J. Brock, London.
17 594. Navigable Vessels, S. Lacavalarie, London.
17,595. Menstruation Bandage, M. Jope, London.
17,596. Inflating Pneumatic Tires, W. E. Kay, Glasgow.
17,597. Making Mortar, W. R. Lake.—*(F. L. Moores, United States.)*
17,598. Pneumatic Tires for Vehicles, F. R. von Felbinger, London.
17,599. Leg-guards, &c., for Cricket, H. S. Matthews, London.
17,600. Military or Travellers' Valise, P. M. Sykes, London.
17,601. Mats, &c., H. Schürholz and A. Stevens, London.
17,602. Coin-freed Machines, H. Burnham, London.

*17th September*, 1894.

17,603. Injectors for Cleaning Bottles, J. Stow, London.
17,604. Jet for Conveyance of Light, T. Goodwin, Bilton.
17,605. Safety-valves, E. G. Hiller and H. Hiller, Manchester.
17,606. Water Indicator, R. H. N. Lindley and F. J. Mudford, London.
17,607. Pumping Engines, L. P. Perkins, G. F. Buck, W. Rose, and O. F. Vollhard, Manchester.
17,608. Duplex Castor, W. Grimshaw, Manchester.
17,609. Bicycles, W. Thomson, Glasgow.
17,610. Lace Machinery, A. E. Slater and A. E. Stroud, Derby.
17,611. Steam and like Motor Engines, J. Pearson, Keighley.
17,612. Cisterns, G. Brindley, J. McEwen, and S. Thompson, Birmingham.
17,613. Duplex Pivot Hinge, E. Spinney, Tunbridge Wells.
17,614. Sliding Hinge, E. Spinney, Tunbridge Wells.
17,615. Cycle Cranks, G. Pirnie, Dundee.
17,616. Pneumatic Tire Fastening, J. T. Grey, South Shields.
17,617. Coal Distilling Apparatus, W. R. Hutton, Lanarkshire.
17,618. Wire or Cord Clip, H. Hirst and W. E. Gibson, London.
17,619. Hanging Window Curtains, J. Kynaston, Liverpool.
17,620. Pneumatic Crutch, G. A. Russell, Newport, Mon.
17,621. Manufacture of Building Blocks, W. Smith, Dublin.
17,622. Cable Tramways, A. B. Wilson, Co. Down.
17,623. Oil Gas Burners and Furnaces, J. Johnston, Dundee.
17,624. Dress Improver, R. P. Dodd and E. Dodd, Birmingham.
17,625. Scouring and Washing Wool, A. Stephenson, Bradford.
16,626. Combing Machines, J. Cooke and A. Stephenson, Bradford.
17,627. Matchbox Cases, W. Sandland and J. T. Martin, London.
17,628. Water-closet Syphon Cisterns, H. Bartlett, Birmingham.
17,629. Butter-working Apparatus, T. Bradford, Manchester.
17,630. Washing Blue, K. Ammann, Manchester.
17,631. Horseshoes, A. Wright, Leicester.
17,632. Catapults, S. S. Hazeland, Cornwall.
17,633. Firebar, H. Hase, Berlin.
17,634. Safety Appliances for Hoists, S. G. Bennett, Smethwick.
17,635. Match and Card Box, W. H. Smyth, Southampton.
17,636. Wedge, J. Reynolds, Wednesfield.
17,637. Measuring Woven Fabrics, J. H. Duckworth, Blackburn.
17,638. Latch Needle Knitters, J. W. Watts, Countsthorpe.
17,639. Luggage and other Labels, W. E. Pierson, London.
17,640. Coal-saving Device for Grates, E. W. Banner, Liverpool.
17,641. Knitting Machine, B. Kerr and I. L. Berridge, London.
17,642. Corsets, W. A. J. Bussey, London.
17,643. Lamp Frame for Heating, S. Whitworth, London.
17,644. Forming Bodies of Canisters, F. W. Durham, London.
17,645. Folding Sheet Metal, &c., F. W. Durham, London.
17,646. Typewriter, G. C. Walker and T. S. Paynter, London.
17,647. Sharpening Scissor Blades, &c., A. R. Catlin, London.
17,648. Method of Sewing Books, W. Davies, Birmingham.
17,649. Enamel Devices, H. H. Wright and N. Lambert, London.
17,650. Boxes, W. T. Pretty, London.
17,651. Dress Fasteners, J. D. Hurst, London.
17,652. Attaching Loose Cuffs to Shirts, A. Clinch, London.
17,653. Bilge Keels and Centre-boards, H. E. Earle, London.
17,654. Safe Deposits, D. R. Ratcliff and J. M. Horner, London.
17,655. Chimney Pots, F. J. Orwin, London.
17,656. Apparatus for Storing Spirits, T. Perry, London.
17,657. Card Case, C. Hunter, London.
17,658. Frame for Photographs or Pictures, E. A. Grimm, London.
17,659. Rock Drills, J. McCulloch, London.
17,660. Fluid Pressure Engines, J. McCulloch, London.
17,661. Ambulance Litters or Stretchers, R. Morgenstern, London.

---

[*] "Proceedings," Institution of Civil Engineers, vol. cxv., 1893-94.

17,662. **Anti-fouling Composition**, R. Hingston and J. P. Wernegreen, London.
17,663. **Apparatus** for **Games**, R. Bodington and H. W. Sharp, London.
17,664. **Knitted Fabrics**, T. Hill and A. D. Whitehead, London.
17,665. **Sleeve Links** or **Solitaires**, A. Ingram, London.
17,666 **Furnaces**, S. Trivick, P. A. J. Head, and J. Elsner, London.
17,667. **Stirrup Ironer**, H. Gattwinkel, London.
17,668. **Dry Batteries**, H. and F. Nehmer and T. A. Reynolds, London.
17,669. **Riddles**, W. S. Barrett, London.
17,670. **Making Articles** from **Mica**, &c., D. Jaroslaw, London.
17,671. **Driving Mechanism** for **Cycles**, J. Bénaset, London.
17,672. **Cutting Metal Joists**, **Bars**, &c., C. Hoppe, London.
17,673. **Car Replacers**, R. E. Alexander, London.
17,674. **Fastening Buttons** to **Leather**, H. F. Welke, London.
17,675. **Carrier** for **Photographic Films**, T. Samuels, London.
17,676. **Preserving Milk** and **Cream**, J. C. Benit, London.
17,677. **Horses' Collars**, W. Williams, London.
17,678. **Sifting Machines** for **Granular Substances**, H. Seck, London.
17,679. **Apparatus** for the **Carburation** of **Gases**, F. Bremme, London.
17,680. **Working Single Line Railways**, I. A. Timmis, London.
17,681. **Car Couplings**, C. A. Gould, London.
17,682. **Valves** for **Steam Engines**, C. W. Thompson, London.
17,683. **Shoe Sewing Machines**, G. H. Scetrini and H. K. Bridger, London.
17,684. **Rubber Pad** to **Insert** in **Stirrups**, G. Martin, London.
17,685. **Transmitting Power**, C. Guest, Manchester.
17,686. **Clothing** for **Horses**, P. Taaffe, London.

18*th September*, 1894.

17,687. **Cycles**, W. F. Humber, R. Cripps, and J. Goddard, Nottingham.
17,688. **Photographic Films**, J. R. C. Gale and J. W. T. Cadett, London.
17,689. An **Improved Door Spring**, J. S. Shelley, London.
17,690. **Feeding-up Machine**, C. B. Bergen, Oldbury.
17,691. **Apparatus** for **Teaching Music**, J. H. Towers, Southsea.
17,692. **Blowers** for **Domestic Purposes**, J. Greaves, Birmingham.
17,693. **Extracting Impurities** from **Gases**, J. W. Scott, Manchester.
17,694. **Weavers' Loom Shuttles**, J. Cooper and J. Wilkinson, Yeadon.
17,695. **Forming Warps** into **Balls**, A. Leach, Manchester.
17,696. **Holding** or **Raising Mattresses**, J. A. Crane, Handsworth.
17,697. **Construction** of **Window Sashes**, A. Coleman, Glasgow.
17,698. **Cutting Steel**, A. Doughty, Glasgow.
17,699. **Supplying Water** to **Urinals**, G. W. Harrison, Leeds.
17,700. **Pad** for **Cycle Seats**, T. Guthrie, W. T. Hall, and The Guthrie-Hall Company, Ld., Newcastle-on-Tyne.
17,701. **Dredging Apparatus**, A. G. Lyster, Liverpool.
17,702. **Cranks** and **Pedals** for **Cycles**, G. Pirnie, Dundee.
17,703. **Feed-water Heaters** for **Steam Generators**, S. Hey.—(*J. O. Davis, United States* )
17,704. **Covering** the **Space between** the **Hinged Side** of a **Door** and **Door Frames**, F. C. Cawdell, Barnsley.
17,705. **Manufacturing Cork Carpet**, J. Ingleby, Leeds.
17,706. **Supplying Gas** on **Prepayment**, J. Hawkyard and J. Braddock, Manchester.
17,707. **Sewing Machines**, A. Anderson.—(*G. Neidlinger, Germany.*)
17,708. **Air Pumps**, A. Dittmar, Glasgow.
17,709. **Pneumatic Tool**, J. Wolstencroft Glasgow.
17,710. **Removing Hair** from **Pelts**, L. Werner, Manchester.
17,711. **Treating Maize**, &c., E. G. Francis, Manchester.
17,712. **Method** of **Conditioning Beer**, E. G. Francis, Manchester.
17,713. **Pneumatic Tires** for **Cycles**, E. G. Francis, Manchester.
17,714. **Furnaces** for **Steam Boilers**, H. Lutz and W. Schaefer, Manchester.
17,715. **Grates** for **Furnaces**, A. G. Brookes.—(*E. Fales, United States* )
17,716. **Method** of **Ventilation**, J. F. Flannery and S. H. Terry, London.
17,717. **Vehicles**, J. Willoughby, London.
17,718. **Construction** of **Discharging Bags**, W. Jordan, London.
17,719. **Designing Patterns** for **Fabrics**, H. L. Cribb, London.
17,720. **Egg Opener**, E. Jouhaud, Enfield.
17,721. **Hoisting Apparatus**, L. Rosenfeld, London.
17,722. **Steam**, **Gas**, or **Oil Engines**, S. H. Berry, London.
17,723. **Paper Fasteners**, G. Hayes, London.
17,724. **Inking** and **Winding Typewriter Ribbons**, S J. F. Guibal, Liverpool.
17,725. **Shielding** the **Openings** of **Dresses**, W. Salmon, London.
17,726. **Eyes** for **Fastening Dresses**, F. E. Windsor, London.
17,727. **Stop** and **Burglar Alarm** for **Doors**, F. Botting, London.
17,728. **Electrically Propelled Vehicles**, E. A. Sperry, London.
17,729. **Shoe-sewing Machines**, G. R. Peare, London.
17,730. **Middlings Purifiers**, T. F. Hind and R. Lund, London.
17,731. **Spraying Liquids**, L. Rusden and R. Eeles, London.
17,732. **Spreader** for **Watering Cans**, W. E. Tidy London.
17,733. **Shoe-horn** for **Boots** and **Shoes**, E. J. Voss, Bexley Heath.
17,734. **Tool** for **Punching Metal Plates**, B. Haigh, London.
17,735. **Preparing Cereals**, A. J. Boult.—(*Catskill Mill Company, United States.*)
17,736. **Air-brake Couplings**, &c, S. W. Summers, London.
17,737. **Insulation** of **Electric Cables**, G. H. Nisbett, Liverpool.
17,738. **Tabulating Statistics**, A. J. Boult —(*H. Hollerith, United States* )
17,739. **Carriage Ventilators**, J. Taylor, Liverpool.
17,740. **Crystals** for **Decorative Purposes**, J. Morris, London.
17,741. **Galvanic Batteries**, W. P. Thompson.—(*A. Lessing, Germany.*)
17,742. **Manufacture** of **Rubber Tubes**, A. J. Boult.—(*The United Berlin-Frankfort Rubber Works Company, Germany* )
17,743. **Vapour Burners**, V. Simonet, London.
17,744. **Brewing Syrup**, L. I. N. Norman, London.
17,745. **Fastening Rail Joints**, G. B. Ellis.—(*The "White" Patent Rail-Joint Company, Ld., Australia.*)
17,746. **Printing Ink**, F. W. Oliver, London.
17,747. **Paint**, F. W. Oliver, London.
17,748. **Clamping Device**, H. J. Haddan.—(*H. S. Buckland, United States.*)
17,749. **Clamp Device**, H. J. Haddan.—(*H. S. Buckland, United States.*)
17,750. **Friction Buckle**, W. Häusler, London.
17,751. **Mandolines** and other **Instruments**, J. Connery, London.
17,752. **Centrifugal Separators**, O. J. R. Ström, London.
17,753. **Velocipedes**, J. Quincy and V. Bélanger, London.
17,754. **Sausage Machines**, H. Lefeber and L. Heuber, London.
17,755. **Coffee Pots**, L. Béchaux, London.
17,756. **Governors** for **Engines** and **Motors**, J. Dow, London.
17,757. **Prepayment Gas Meters**, W. N. Milsted, London.
17,758. **Photographing** in **Colours**, V. Mathieu, London.
17,759. **Artificial Fuel**, W. B. Hartridge, London.
17,760. **Artificial Fuel**, W. B. Hartridge, London.
17,761. **Electric Arc Lamps**, J. Brockie, London.
17,762. **Paper Cuff Protectors**, &c., F. C. Watts, London.
17,763. **Draught Regulators**, C. F. Kaul, London.
17,764. **Self-acting Disinfecting Closets**, T. Temple, London.
17,765. **Gas Engines**, Tangyes, Ld., and A. J. Lester, London.
17,766. **Hydraulic Motors**, E. F. Piers, Bart., London.
17,767. **Cleaning Trunks**, B. Willcox.—(*J. C. Potter, United States* )
17,768. **Band Cutters** and **Feeders**, V. C. Bailey, London.
17,769. **Shears**, P. R. J. Willis.—(*D. H. Hollingsworth, United States.*)
17,770. **Grinding Cocks**, C. M. Jarvis and R. S. Byron, London.
17,771. **Generating Steam** by **Gas**, W. Felton, London.
17,772. **Air Compressors** for **Tires**, J. A. Clarke, London.
17,773. **Mud-guards** for **Cycles**, &c., W. R. Ridings, London.
17,774. **Electric Signal**, The Phonopore Company, Ld., and E. W. Smith, London.
17,775. **Washing Machines**, E. J. Hodge, London.
17,776. **Tips** for **Billiard Cues**, W. R. Yates, London.
17,777. **Screens**, A. M. Jones, London.
17,778. **Advertising**, H. Downer, London.
17,779. **Paper-making**, T. A. and C. D. Marshall, London.
17,780. **Water Meters**, A. J. Boult.—(*T. Derichs and Messrs. Hegenscheidt Bros.*, ———.)
17,781. **Clutch Speed Mechanism**, J. Redding, London.
17,782. **Sketching Canvas Holder**, J. G. Jones, London.
17,783. **Attaching Heels** to **Boots**, T. Peberdy and W. Earp, Leicester.

19*th September*, 1894.

17,784. **Galley**, A. W. Townshend, London.
17,785. **Reflector**, F. J. Borland, Leeds.
17,786. **Circular Weaving Machine**, C. T. B. Brain, Liverpool.
17,787. **Filters**, L. Padé, Manchester.
17,788. **Woven Fabrics**, A. Brunton and A. Hewitt, Manchester.
17,789. **Driving Gear** for **Dynamos**, G. Twigden, Bristol.
17,790. **Mild Steel Railway Chairs**, T. Williamson, Wishaw, N.B.
17,791. **Furnaces**, S. Wilson, Bedford.
17,792. **Faller Motion** for **Self-acting Mules**, J. Lees, Oldham.
17,793. **Paper Bags**, F. E. Hollyer, Brentford.
17,794. **Frame** for **Cycles**, W. Earp and W. Askham, Nottingham.
17,795. **Vehicles**, J. Inglis, Glasgow.
17,796. **Stiffenings** for **Corsets**, &c., J. M. Ballantyne, Glasgow.
17,797. **Window Fastener**, J. Kennedy, Glasgow.
17,798 **Gearing** for **Velocipedes**, C. R. Garrard, Worcester.
17,799. **Deal**, **Batten**, and **Board Elevator**, P. E. Robilliard, Guernsey.
17,800. **Pneumatic Safety Appliance** for **Boats**, A. Johnson, London.
17,801. **Coin-freed Automatic Machines**, R. Gell, Douglas, Isle of Man.
17,802. **Firing Keys**, H. C. L. Holden, Woolwich.
17,803. **Pyramid Margarine Boxes**, W. McDonnell, Limerick.
17,804. **Food** for **Horses** and **Cattle**, A. Neumann, Manchester.
17,805. **Insulating Hot Chambers**, M. C. Bannister, Manchester.
17,806. **Preventing Straining** in **Machinery**, H. C. Lobnitz, Glasgow.
17,807. **Children's Carriages**, W. S. McLennan and T. Morton, Glasgow.
17,808. **Electric Arc Lamps**, H. Lyon, Glasgow.
77,809. A **Trousers Suspender**, G. Franke, London.
17,810. **Velocipedes**, C. Renysen, Birmingham.
17,811. **Speed Gearing**, G. E. Graves and W. A. Webb, Newcastle-on-Tyne.
17,812. **Checking Engines**, E. Waddington, Barrow-in-Furness.
17,813. **Railway Porters' Lamps**, C. Tennett and H. Leggott, Bradford.
17,814. **Newspaper Self-binder**, E. G. Parry, Llandudno.
17,815. **Coupling Main Driving Ropes**, W. Haigh, London.
17,816. **Horseshoes**, G. B. Birch, Birmingham.
17,817. **Bottle Stopper**, F. W. Kitto and W. Haworth, London.
17,818. **Bottle Stoppers**, A. J. Boult.—(*M. W. Nachfolger, Germany* )
17,819. **Keeping Foods Hot**, E. W. Crebbin and J. W. S. Holt, Liverpool.
17,820. **Soldering Aluminium**, W. P. Thompson.—(*O. Nicolai, Germany.*)
17,821. **Device** for **Testing Drain Pipes**, R. T. Bells, Birmingham.
17,822. **Raising** or **Lowering Curtains**, J. W. Hinchliffe, London.
17,823. **Weighing Machines**, J. C. B. Jones, Liverpool.
17,824. **Razors**, C. W. S. McHugh, London.
17,825. **Speed Indicators** for **Vehicles**, T. S. James, London.
17,826. **Tires**, H. Parsons, London.
17,827. **Luggage Carrier** for **Cycles**, H. J. Owers, London.
17,828. **Shoe** for **Sculls**, E. W. Aldridge, F. W. Moss, and H. Thornton, London.
17,829. **Self-righting Lifeboat**, E. W. Aldridge, F. W. Moss, and H. Thornton, London.
17,830. **Fire-resisting Curtains**, &c., E. Taylor, London.
17,831. **Chainless Gear** for **Cycles**, W. Rose, London.
17,832. **Decoration** of **Movable Surfaces**, A. Mudie, London.
17,833. **Coat**, I. Finberg, London.
17,834. **Washing** and **Wringing Machines**, H. Heinrichs, London.
17,835. **Driving Mechanism** of **Cycles**, L. Clement, London.
17,836. **Drying Apparatus**, W. W. Wardle, London.
17,837. **Engine Reversing Mechanism**, C. E. R. Martin, London.
17,838. **Cycles**, W. R. Lake.—(*Freeman High Speed Bicycle Company, United States.*)
17,839. **Sewing Boots** and **Shoes**, &c., W. E. Tyrrell, London.
17,840. **Combination Sleeve-links**, C. E. Whitlock, London.
17,841. **Shaping Necks** of **Bottles**, H. H. Lake.—(*W. Painter, United States.*)
17,842. **Carriages** for **Common Roads**, A. W. Knight, London.
17,843. **Axle-boxes** for **Locomotives**, J. Richardson, London.
17,844. **Photographic Shutters**, C. P. Goerz and E. R. Nerrlich, London.
17,845. **Electric Lamps**, J. Devonshire.—(*E. Thomson, United States.*)
17,846. **Electric Lamps**, J. Devonshire.—(*E. Thomson, United States* )
17,847. **Construction** of **Buildings**, F. W. Holloway, London.
17,848. **Apple Wine** and other **Presses**, C. J. Ollagnier, London.
17,849. **Appliance** for **Supporting** the **Arch** in **Cases** of **Flat Feet**, W. S. Melsome, London.
17,850. **Shaving** and **Paste Brushes**, S. M. Holmes, London.
17,851. **Nuts**, E. J. O'Neill, London.
17,852. **Tidal Motor**, D. Newell, London.
17,853. **Hauling Apparatus**, A. Taylor, London.
17,854. **Printing Blocks** or **Plates**, W. A. Day, London.
17,855. **Cycle** and **Carriage Wheels**, W. H. Serjeant, London.

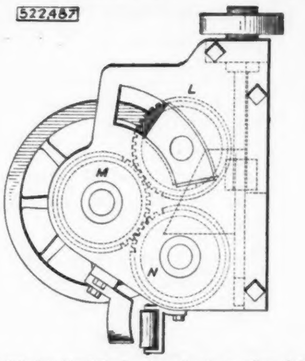
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**522,487.** **Machine for Flaring and Bending Hoops**, *J. Pleukharp and T. Schramm, Columbus, Ohio.—Filed May* 20*th*, 1893.

*Claim.*—(1) In a hoop-flaring machine, the combination of a series of three rollers, L, M, and N, guides for the bearing of the roller L formed on the arc of circles whose centres coincide with the axis of the roller M, a slide having inclined portions to engage with the said bearings, and a screw for moving the said slide to adjust the bearings to change the relative position of the said roller L, substantially as and for the purpose described. (2) In a machine for flaring hoops the combination with a frame having slotted slides, bearings arranged within the slots, rollers journalled between the sides, a roller journalled in the bearings, a slide having an inclined face adapted to bear upon the bearings and adjust the same and means for moving the said slide back or forth, substantially as shown and described.

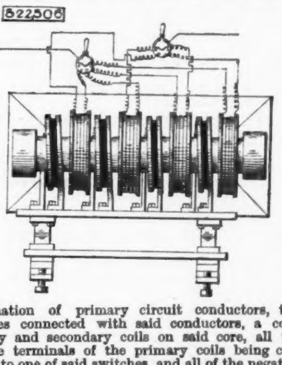
522487



**522,506.** **Electric Converter**, *G. D. Purton, Boston, and E. E. Angell, Somerville, Mass.—Filed November* 14*th*, 1892.

*Claim* —(1) In an electric converter the combination of two standards provided with eyes at their upper ends, a tubular sheath disposed at its opposite ends in said eyes, iron rods disposed in said sheath, primary and secondary coils disposed on said sheath, the secondary coils having rigid terminal arms and plates connecting said arms of the same polarity. (2) The combination of primary circuit conductors, two switches connected with said conductors, a core, primary and secondary coils on said core, all the positive terminals of the primary coils being connected to one of said switches, and all of the negative terminals of said primary coils being connected to the other switch, said secondary coils having horizontal arms constituting terminals, and a positive pole plate attached to one set of said arms, and a negative pole plate attached to the other set of said arms, substantially as set forth.

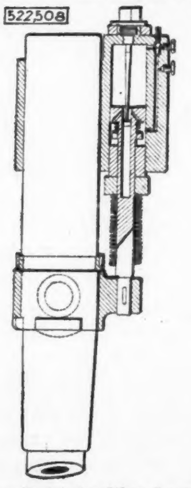
522506



**522,508.** **Recoil Check for Ordnance**, *J. B. G. A. Canet, Paris, France.—Filed February* 9*th*, 1893.

*Claim.*—(1) In a gun mounting, a hydraulic brake apparatus comprising a cylinder, a piston and hollow piston-rod, apertures leading through to the front of the piston from the interior of the rod, a spring loaded non-return valve for closing said apertures to allow the liquid to flow therethrough in one direction only, a taper spindle secured to the cylinder end and adapted to enter the piston-rod and control the area of the outlet opening for the liquid during recoil, a thoroughfare forming a communication between the ends of the brake cylinder on opposite sides of the piston, and an adjustable screw valve operated from the exterior of the brake cylinder for controlling said thoroughfare, and regulating the speed of running out the gun, substantially as set forth for the purpose specified. (2) The combination with a gun, of a hydraulic brake cylinder, a thoroughfare formed in the cylinder to communicate with the opposite ends thereof, an adjustable screw-down valve for closing said thoroughfare, and apertures leading into the thoroughfare at opposite sides of the adjustable screw-down valve and provided with non-return valves, said apertures being adapted to receive the delivery pipe of a force pump to run the gun in or out when the adjustable screw down valve is closed, substantially as described.

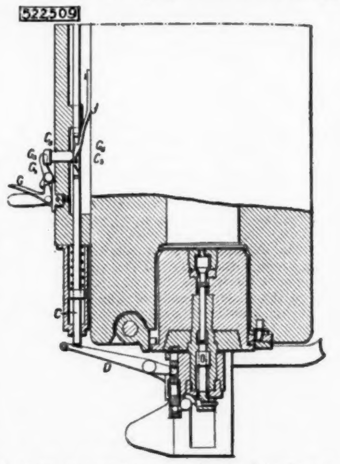
522508



**522,509.** **Firing Mechanism for Ordnance**, *J. B. G. A. Canet, Paris, France.—Filed April* 27*th*, 1893.

*Claim.*—(1) In a breech-loading gun, the combination of a bracket or support, a recoiling gun, trigger mechanism and an actuating lever therefor mounted on and carried rearward by the recoiling of the gun, and lever operating mechanism arranged in operative connection with said bracket or support, and set to operate the actuating lever of the trigger mechanism by the forward movement of the gun, substantially as described. (2) In a breech-loading gun, the combination, with the gun and its trigger mechanism, of a hook J secured to a part that recoils with the gun, and an axially movable spring-controlled rod C adapted to be engaged by said hook and to be moved forward to compress the controlling spring thereof during the running out of the gun, the rear end of said rod being in a position to strike the firing lever when released from the hook, substantially as described for the purpose specified. (3) The combination, with the gun and its trigger mechanism, of the hook J secured to a part that recoils with the gun, a spring-controlled rod C adapted to slide axially in fixed bearings on the gun carriage, and to be engaged by said hook J during the running out of the gun, the rear end of the said rod being in a position to strike the firing lever D when released from the hook J, and means for disengaging the hook J and thus liberating the rod C, substantially as and for the purpose specified. (4) The combination, with a gun and its trigger mechanism, of a spring controlled rod C axially movable in stationary bearings, and the rear end of which is adapted when released to strike the firing lever D, a slot $C^3$ in said rod, a hook J secured to a part that recoils with the gun and adapted to enter said slot $C^3$ and thus engage the rod C, and the pin $G^2$, lever $G^3$, and lever G for disengaging the hook J from the rod as required, substantially as and for the purpose specified. (5) The combination, with a gun and its trigger mechanism, of a spring-controlled rod C axially movable in stationary bearings, and the rear end of which is adapted when released to strike the firing lever D, a slot $C^3$ in said rod, a hook J secured to a part that recoils with the gun and adapted to enter said slots $C^3$ and thus engage the rod C, the pin $G^2$, lever $G^3$, and lever G for disengaging the hook J from the rod as required, an inclined part $C^4$ at the forward end of the slot $C^3$, and a corresponding inclined part $G^5$ on the end of the pin $G^2$, whereby the said pin is moved out again during the rearward movement of the rod C when said rod is released, substantially as described for the purpose specified.

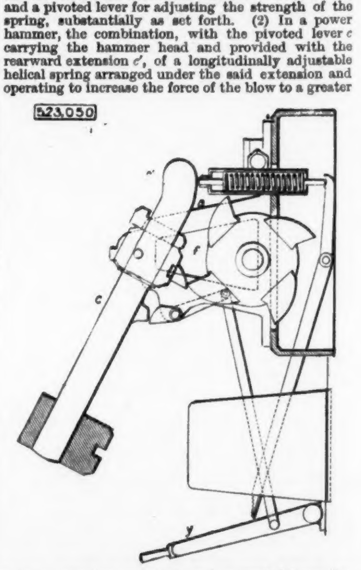
522509



**523,050.** **Machine for Forging or Hammering Metal**, *L. A. Parrock, Birmingham, England.—Filed October* 2*nd*, 1893.

*Claim.*—(1) In a power hammer, the combination, with the pivoted lever *c* carrying the hammer head and provided with the rearward extension $c'$, and the segment *f* below its pivot; of a spring operating on the said extension to increase the force of the blow, and a pivoted lever for adjusting the strength of the spring, substantially as set forth. (2) In a power hammer, the combination, with the pivoted lever *c* carrying the hammer head and provided with the rearward extension $c'$, of a longitudinally adjustable helical spring arranged under the said extension and operating to increase the force of the blow to a greater or less extent as required, and a pivoted lever for adjusting the said spring, substantially as set forth. (3) In a power hammer, the combination, with the standards *a*, of the hammer lever pivotally supported by the said standards and provided with the projection *v*, the handle *y* pivoted in one of the said standards and provided with a cam-shaped stop *u*, arranged under the said projection, a pivoted lever at the front of the anvil, and a rod pivoted to the lever and handle for operating the said handle, substantially as set forth.

523050



## WHITWORTH SCHOLARSHIPS.

We have received from time to time so many letters upon the subject of the Whitworth Scholarships, inquiring for particulars as to regulations and also for advice, that we think it desirable to put in a concise form some account of the history of these prizes, and if possible to assist those of our younger readers who may become competitors. The desire of Sir Joseph Whitworth—then Mr. Whitworth—to assist in forming a faculty of engineering similar to the faculties of divinity, law, and medicine, led him on 18th March, 1868, to write to the Right Hon. B. Disraeli, M.P., offering to found thirty scholarships of the annual value of £100 each to be applied for the further instruction of young men, her Majesty's subjects, of the United Kingdom, India, or the Colonies, selected by open competition for their intelligence and proficiency in the theory and practice of mechanics and its cognate sciences.

The first competition was to be held in 1869, and the age of competitors was not to exceed twenty-six years. Candidates were to be of sound bodily constitution, and equal credit was to be given for proficiency in handicrafts as in theory. As the scheme could only come into use gradually—for it was proposed that each scholarship should be tenable for three years—ten scholarships were offered for competition in May, 1869, and sixty exhibitions or premiums of the value of £25 each were put absolutely at the disposal of various universities and colleges, to be awarded by them in 1868 to students under twenty-two years of age who should undertake to compete for the scholarships of £100 in May, 1869. The deed by which the necessary endowment was made sets forth that Mr. Whitworth desired to assist the Education Department to regulate the competition during his own lifetime, and thereafter to enable the committee to alter the regulations as might seem best. The scholarships were each to be tenable for two or three years, as might seem preferable. The whole of the examinations were to be carried out by the Science and Art Department at their ordinary May examinations.

In the first year's competition, 1869, the first name upon the list is William H. Greenwood, aged twenty-three, who obtained 74 marks for theory and 69 for practical work—making a total of 143. John Hopkinson, B.Sc., aged nineteen, student of Cambridge University, appears third on the list, with 122 marks for theory and 12 for practical work—making a total of 134. This is the gentleman who is now Dr. John Hopkinson, and has attained such a prominent position in the engineering world. The examination in the use of tools was very practical; for example, under the heading of axes, we find the competitor was required to true up an octagonal block of wood like a sample block, using the axe only; to make an axe haft like a pattern, using axe and spokeshave. In fitting he had to chip a piece of cast iron over the top surface; file up any two adjacent sides of a cast iron cube, giving the file 9in. stroke. In the earlier years the competition was divided between students and workmen; the theoretical part of the examination was the same for both, but the practical part required a higher standard of attainment on the part of the workmen. In the year 1870 among other names, we find that of John Perry, now so well known from his work in connection with his co-professor, Mr. Ayrton.

In the year 1873 it was specially pointed out to intending competitors that the scholarships were not founded with the object of rewarding past merit, but as an aid to further study. Those who had shown most proficiency in theory would be required to follow practical work, and *vice versâ*. Sir Joseph Whitworth offered to allow the scholars to attend his shops at Manchester free of cost. The scholar was not to be allowed to take a place of profit, or to continue in any business he might be engaged in when he obtained a scholarship, but was to devote himself to completing his education at some place of study approved by the Department. Robert H. Smith's name heads the list of successful scholars for 1872, and he has since become Professor Smith, of Mason College, Birmingham.

In July, 1873, a change was made in the tenure of the scholarships, and it was decided that in the competition of 1875 every candidate for a scholarship must produce a certificate that he had worked in a mechanical engineer's shop, or in the drawing-office of a mechanical engineer's shop, for two years consecutively, but in 1874 only six months' consecutive work was required. The candidates were to be under twenty-two years of age. In 1875 and the following years each holder of a scholarship was required to produce satisfactory evidence at the termination of every year that he had made proper advances in the science and practice of mechanical engineering by coming up for an examination similar to that prescribed for the competition. The number of scholarships was reduced from ten to six; each was of the fixed annual value of £100, but bonuses were also payable, so that if one scholar were first in all the three years he would be awarded a total sum of £800. We have looked over the lists of successful competitors, and find that one William Sisson, aged twenty-one, of Gateshead, was successful in 1874, and during the term of three years was paid in all £780. We should like to know what has become of this gentleman, and what his success in the profession has been. In fact, we may say that we feel it would be a very desirable thing to collect information as to the life-history of all the Whitworth Scholars, with a view to seeing what positions they have attained in the profession.

New rules were brought out for the award of Whitworth scholarships in 1879. In that year they were (*a*) of the value of £125 tenable for three years, and (*b*) £200 in one sum; the successful candidates had the option of selecting which they preferred. Eight scholarships were offered for competition, and it was not necessary that the candidates should be examined each year they competed, in all the essential subjects. There were no conditions applicable to the scholarships of £200 in one sum; but for those of £125 for three years it was stipulated as before that the holder should give up his situation and devote himself to study, proving his advances each year.

For the year 1880 there were again changes; the scholarships were open to competitors who were of sound bodily constitution, who had not completed the twenty-second year of their age before May 1st of that year; and it was necessary that they should have spent at least six consecutive months in each of three successive years at handicraft. These changes were brought about by Sir Joseph Whitworth himself, who stated on December 13th, 1878, that after ten years' experience he had come to the conclusion that the withdrawal of a student from his business for three years seemed specially to militate against the success of the scheme as a means of improving the technical education of mechanical engineers in this country. From and after 1882 there were to be annually one scholarship of £200, eight of £150, and sixteen of £100, and these were to be awarded annually. The age of candidates was changed to twenty-six, as at first.

The report for the year 1883 recounts that from the year 1869 to 1873, both inclusive, ten scholarships were awarded each year of the annual value of £100 for three years. Of the fifty scholars appointed under these rules, thirty-one were believed to be engaged in business or professional work, eleven in teaching, two dead, and the Science and Art Department had no information relating to the other six. From 1874 to 1878 inclusive the scheme of bonuses previously described was adopted, and the limit of age reduced to twenty-two years, while the entire "student" class was shut out owing to the requirement of two years' workshop experience. Thirty-two scholars were appointed, and of these in 1883 twenty-one were believed to be engaged in business or professional work, four in teaching, and no data were available of the other seven. By the regulations, all candidates were required to give evidence of their practical skill in handicraft, and this might be tested if thought necessary by the Department.

In the thirty-third annual report of the Science and Art Department will be found an abstract of reports from Whitworth scholars appointed between 1869 and 1883 inclusive, stating the profession or occupation in which they have been engaged since the expiration of their scholarships. This is very interesting reading, and shows what has become of most of the men. We see sketches of the history of Professor Greenwood, of Firth College, Sheffield, Dr. John Hopkinson, Professor Garnett, Professor Perry, Professor R. H. Smith, of Birmingham, W. R. Bousfield, Q.C., Professor Hele Shaw, of University College, Liverpool, Professor Ryan, of Bristol, &c.; and we would recommend future competitors to refer to this report—page 59—and read these abstracts. The rules as applicable to the examinations in 1888 and future were altered as follows:—Whitworth exhibitions are some of them of the value of £100, and others of the value of £50 each, tenable for one year only. The scholarships are of the value of £125 a-year, tenable for three years. A candidate must not have completed his twenty-sixth year at the date of the examination. He must have been engaged in handicraft in the workshop of a mechanical engineer for at least three years on the 1st May of the year in which he competes, and have been at work at the vice and lathe or the forge or the bench during working hours for at least six consecutive months in each of those years. Twenty £100 exhibitions, ten £50 exhibitions, and four scholarships of £125 a year, tenable for three years, were competed for in 1888. Ten £100 exhibitions, twenty £50 exhibitions, and four scholarships of £125 a year, tenable for three years, were competed for in 1889; and since that date thirty £50 exhibitions and four scholarships of £125 a year, tenable for three years, in each year. The candidates are divided under three headings: (*a*) those who are or intend to be engaged in machine making, cotton, woollen, flax, &c.; or in engineering—marine, locomotive, and fixed; or in artillery. (*b*) Those engaged in the building trades and coachmaking. (*c*) Those engaged in naval architecture. The subjects are slightly different for each of these classes. Each exhibitioner will be required to submit, for the approval of the Department, a scheme of work or study for the year of holding his exhibition, and considerable latitude is allowed. On the approval of his scheme half the money will be paid, and the other half is paid on receipt of a satisfactory report at the end of the exhibition year. Exhibitioners are permitted to hold posts of profit or emolument while holding their exhibitions. No person can take an exhibition twice, but if otherwise eligible may compete in a subsequent year for a Whitworth scholarship. The competitors who obtain the scholarships are required to devote their time entirely to the prosecution of their education as mechanical engineers.

Before the scholarship can be finally awarded, the scholar must propose for the approval of the Department of Science and Art precisely how he will spend his time during his tenure of the scholarship, and it must be clearly understood that the tenure is subject to the condition that he pursues such a course of work. The payments are made half-yearly, and each payment is only made after the receipt of a satisfactory report. No holder of a scholarship can compete for a Whitworth exhibition. It is now considered sufficient to obtain a certificate of proficiency in practical work, but the Department reserve to themselves the right of testing a candidate's ability by requiring him to make two Whitworth screw bolts 1in. in diameter and 4in. to 6in. long, with hexagonal heads and nuts, alike within 0·001in.

The last set of rules still apply to the competition, and although, as we have seen, Sir Joseph Whitworth considered it was not advisable to cause the young engineer to give up all his practical work for three years, still, in the judgment of the Science and Art Department, it has been thought best to give a limited number of three years' scholarships.

The young aspirant for honours is usually anxious to know what is the best plan to follow when in preparation for the examination, what books to read, and where to study. We do not think any hard-and-fast rules can be laid down, but we believe the practice of most competitors to have been to work during the day in the shops while serving their time, and to attend evening classes for theoretical training. If a young man wishes to make his way in the world he will find this quite a feasible plan; in fact, after a day's manual labour he will probably find himself fresher for study than if he had been poring over a desk in an office. The practical work is absolutely essential, and cannot be shirked. The scholarships are not intended for the mere student, but for the practical man. In case a competitor is successful in obtaining a scholarship, he must of course devote himself according to the rules solely to study, and our opinion is that he would do well to attend one of the fine technical colleges either here or abroad, preferably the latter, as he would then be able to get such a solid practical acquaintance with one or more languages as would be found exceedingly useful in after life. If his time were divided—say, eighteen months at a French college and eighteen months at a German college—he ought, on the completion of his term, to be a very valuable man. On his return to England he should at once aim at taking a subordinate post in some large works, and his training should, while abroad, have been specially in one direction as much as possible. For example, he should have made a speciality of mechanical engineering, electrical engineering, or some other branch. His early mechanical training in the workshop would form the basis for the whole of his subsequent training, and is invaluable. By foreign travel the youth's ideas would be widened; and though we hear occasionally, especially in the North of England, foreign practice spoken of slightingly, there is no doubt it is a valuable addition to the knowledge of any engineer. With respect to books for study, it would be invidious to make a selection; that can safely be left to the professors of the evening classes which would be attended by the intending competitor.

One last word. We have had inquiries as to the addresses of "grinders;" we cannot give them, and if we knew them we should not think it desirable to give them if a system of cramming is to be pursued. It is useless for any young man to attempt in the short space of a few months to cram up a lot of formulæ and rules-of-thumb, and so hope to be successful. Steady and continuous study is necessary, and few young men are in a sufficiently easy financial position to pay a private tutor for such a lengthened course.

Advantages are now offered to young engineers which were by no means available twenty years ago; and it is quite possible first to obtain an exhibition which will materially assist the student, and help him eventually to win a Whitworth scholarship. The critical point in the career of the successful scholar is at the end of his third year; he feels perhaps that it is not to his taste to go back into the works or to obtain a post as outdoor foreman, and tends to diverge into science teaching. This should be carefully avoided. The object set before him by Sir Joseph Whitworth was the assistance of the mechanical engineer to rise in his profession as an engineer. Some few men of genius have been able to combine professional work with professorial work, but the majority of those who begin to teach will gradually and surely lose touch with practical work—at least that is our experience.

## BELGIAN EXHIBITS AT THE ANTWERP INTERNATIONAL EXHIBITION.

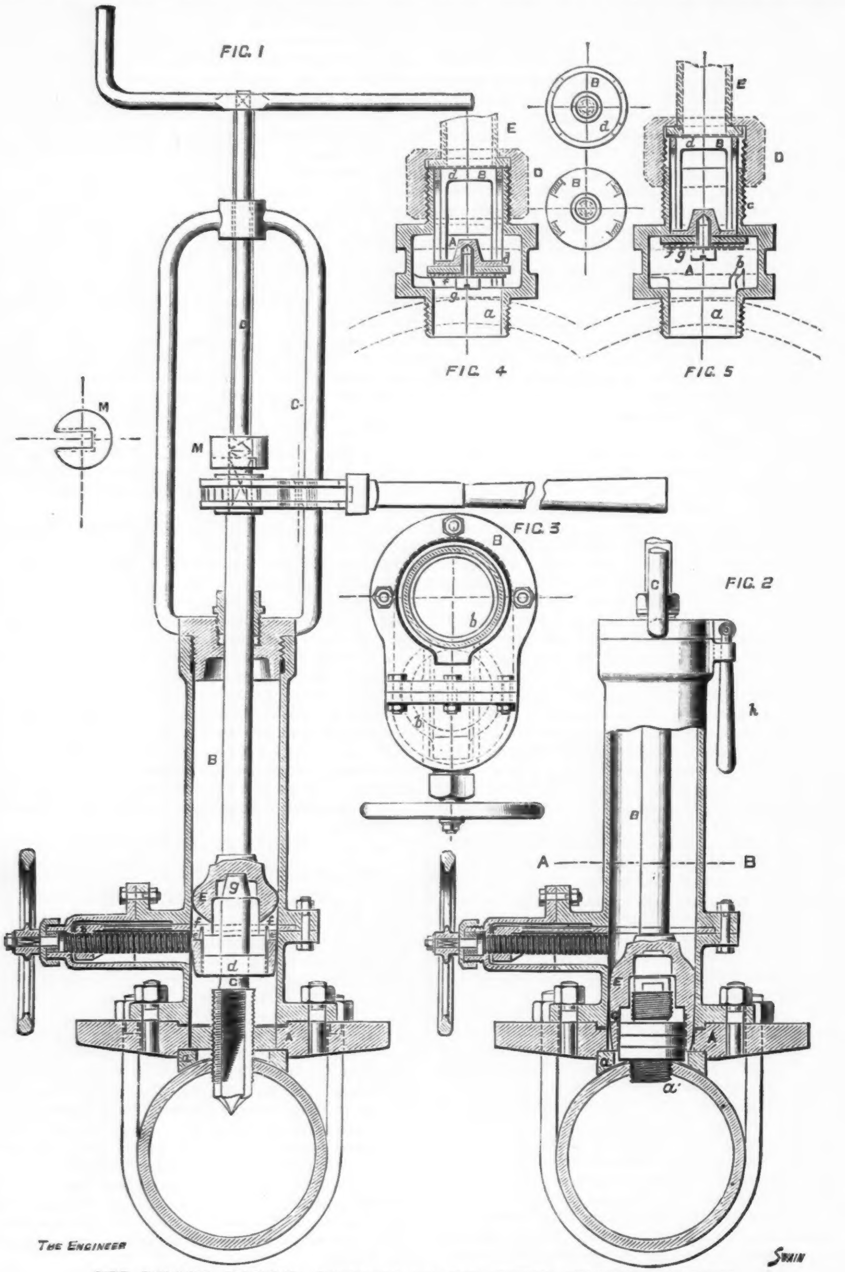
(*From our Special Commissioner.*)

One of the most conspicuous objects in the Main Exhibition Building is a trophy of cast iron gas and water pipes, surrounded by gas valves, penstocks, retort doors, &c., forming the exhibit of the Compagnie Générale des Conduites d'Eau, of Vennes, near Liége. This trophy, which serves to introduce bends, T pieces, and other joints, commences with pipes 4ft. 1in. internal diameter. It is 46ft. high, and the weight of the castings which form it is over 100 tons. The Vennes Foundry Company states that it exports more cast iron than all other firms in Belgium taken together. At its stand is a list of cities and towns in all parts of the world whose waterworks and gasworks have been supplied by it. To mention a few, I observe that it has had the contract for the gasworks of Lisbon, Madrid, Malaga, Alicante, Rio Janeiro, and Ostend; and for the waterworks of Turin, Lisbon, Windsor (in Canada), Guatemala, Huelva, and Pireus.

The chief novelty is a machine which the company has recently patented for drilling, tapping, and connecting a small pipe to a large one; whilst the latter is filled with water, or other liquid, under pressure. By using this apparatus there is no loss of the liquid contained in the large pipe; neither is any permanent saddle nor strap required. In the illustrations, Figs. 1 to 3 show the method of drilling the hole and fixing the connection in place. The saddle A, Figs. 1 and 2, has four slots in it, converging towards the centre, and enabling different-sized straps to be used, according to the diameter of the pipe to be drilled. The lower side of the ring *a*, on which the saddle rests, also varies according to the size of the pipe, and its interior diameter is large enough to allow the connecting piece to pass through it. The body of the apparatus, B, is bolted to this saddle, and a circular valve *b*, conical in section, and shown in plan on Fig. 3, can be screwed down by means of a hand-wheel when the tool has been removed, and it is necessary to take away the upper strap C in order to insert the connecting piece. This valve closes like the door of a penstock; and when closed the pressure of the liquid helps the pressure of the screw to keep it tight. The strap C is fastened to B with a bayonet joint, and it carries a screw D, whose thread is to the same pitch as that of the point of the connecting piece marked *a* in Fig. 2. The small safety handle *h*, shown at the top of

Fig. 2, is to keep the thread from unscrewing when the apparatus is fixed. The tool-carrier E, which is properly centred in C, first holds the tool, which is a combined drill and tap, and afterwards the connecting piece.

In working, the pieces *a*, A, and B are placed over the place where the connection is to be made, firmly secured by the straps, and the slide *b* is drawn back. The tool G is then placed in the tool-holder, where it is held in place by the springs *e e*. The upper strap C with its connections is then put on, and the hole drilled, either by turning the handle at the top, or, if necessary, by means of the ratchet-brace handle. When the hole has been drilled, the piece M—Fig. 1—which joins the head of the tool-holder to the bottom of D, is placed in position; the hole is then tapped by means of the upper handle. As soon as the hole has been drilled and tapped, the upper handle is reversed until the tool has been raised sufficiently high to allow of the slide *b* being closed. C is then taken down, the tool removed and replaced by the connecting piece—Fig. 2—which also fits into the tool-holder, and is kept in place by the two springs *g g*. It is then only necessary to replace *c*, and to screw down the tool-holder till the point *a* of the connecting piece enters the hole which has just been made. The apparatus can then be taken down.



PIPE DRILLING MACHINE, EXHIBITED BY THE VENNES FOUNDRY COMPANY

The shape of the connecting piece can be seen more clearly from Figs. 4 and 5. It consists of two essential parts, the lower solid piece A, and the valve B. In A there is a centre part *b* into which the bottom of the valve B descends, the upper end *c*, on to which the cap D is screwed, and the lower end *a*, which is screwed into the main pipe. This point is slightly conical, and it has been so screwed that whilst the first turns of the thread correspond exactly with that of the main pipe, the rest are a little larger in diameter; and, as the metal in this connecting-piece is softer than the cast iron of the main, it is, when screwed up tight, so compressed as to fill every crevice in the latter, and make a perfectly water-tight joint.

The main part *d* of the valve B fits into C, and a joint of leather, india-rubber, or asbestos, according to the nature of the liquid in the pipes, is held up by a hexagonal plate *f*, and a screw *g*. If desired, a spring can be introduced into *d* to balance the weight of the valve, but this is rarely considered necessary, as the slightest pressure of water is sufficient to keep the joint tight.

Until the connecting piece is in place, the valve B occupies the position shown on Fig. 4; the cap D and branch pipe E are only connected with it after it is in place. Directly it has been screwed into position, the pressure of the water lifts the valve B, and presses it against its seating, as shown on Fig. 5. The cap D, which carries the branch pipe, is now screwed on to *c*, and, as D is screwed down, the valve B is forced to descend. The main and branch pipes are then in connection, as shown on Fig. 4. When it is necessary to shut off the water from the branch, this can be done by unscrewing D and allowing the pressure to lift the valve B. As the valve is carefully centred, and with long guides, it is not likely to get out of order, or to require repairing from any reason; but if it has to be removed, the connecting piece can be taken out by the same apparatus which was used to insert it, and a plug substituted. In that case a little thin red lead should be put on the screw before replacing it.

The Vieille Montagne Company has an elegant little kiosque at the beginning of the Belgian section. It is covered with zinc tiles, painted with white oxide of zinc paint, and serves to display specimens of zinc in different stages of manufacture, and examples of the different purposes to which it can be applied. Commencing with samples of ore, they pass on to ordinary or commercial zinc, considered sufficiently pure for the manufacture of galvanised iron, or for remelting with copper to produce bronze. Samples of these are shown, as well as models of roofing covered with galvanised corrugated iron. A better quality of zinc is used for rolling into sheets, and a series of these are exhibited, running from $\frac{1}{250}$in., up to $\frac{1}{8}$in. Next come the applications of sheet zinc in tubes, gutters, Italian and ordinary corrugations, and roofing tiles, both plain, lozenge-shaped, and ornamental. Models of roofing made with these tiles are exhibited, including domed roofs, in which the size of each course of tiles is slightly less than that of the one below. Other applications of sheet zinc to roofing, such as cresting, finials, and cornices, are also shown. As examples of other forms in which zinc is used, it exhibits nails, wire, perforated sheets, sheathing for vessels, zinc plates for suspending in boilers to prevent corrosion or incrustation, and plates for zincography. The purest quality of zinc, which is found on analysis to contain less than one half-thousandth part of foreign matter, is used chiefly in the production of brass for cartridge cases. Of nearly equal purity is the metal from the ores of Moresnet, and this is employed for the manufacture of artificial bronze, chiefly for statuary. Finally it shows various forms of zinc plates for electrical purposes.

Considering the enormous consumption of beer in the Exhibition grounds, and indeed in the whole of Belgium, one would naturally expect that the show of brewery plant should be important. But though it covers a large space, it chiefly consists of bottle washing and bottling machinery, cooling apparatus, and various appliances such as counter fittings, which are connected rather with the consumption than with the manufacture of beer. One or two small coppers are shown, and five or six mash tuns about 8ft. in diameter. A peculiarity about these is that the makers do not seem to agree as to the best method of arranging the rousers. Thus M. Désiré Mathieu, of Thuin, exhibits a mash tun with the driving wheel running on a rack round the interior, and three arms on each side, each set with thirty-two beaters 9in. long. In M. Aug. Lermusiaux, of Jemappes, mash tun there is a horizontal shaft with vertical beaters on one side, and a vertical shaft with horizontal beaters on the other. Messrs. Struyf and Coppens, of Antwerp, have one resembling the above, but with the shafts which carry the vertical beaters curved. This firm exhibit a complete plant, engine, boilers, &c., including some copper pipe coolers of the usual type. Similar brewery plant is shown by M. de Coster Van de Velde, of Thielt, and M. F. Lermusiaux, of Antwerp, who both also exhibit mills, cleaning machines for malt, &c.

The most interesting collection of appliances in this section is that of Messrs. Pfaffenberger Brothers, of Brussels. One of these is a cooler, called the "Victoria Refrigerator." In this the beer to be cooled enters a trough at the top, and flowing over the edge on to the irregularly-shaped sides, which are made of tinned copper, falls in small cataracts to the bottom, where it is collected in another trough. Between the copper sides water circulates in the usual manner, but the peculiarity of this machine is that though iced water is used, ordinary water can be employed as well, thus economising the former. The ordinary water is passed through the upper part of the cooler, and the iced water through the lower part, so that they really form two separate machines, one above the other, though they can be connected when all the cooling water which is being used is of the same temperature. Another exhibit at this stand is an apparatus for washing bottles, called "La Rapide," and capable of cleaning two thousand per hour. An octagonal frame, carrying iron cylinders which are long enough to hold three bottles each, revolves in a tank filled with water. This takes five minutes to revolve, and as a bottle is removed another is pushed in behind, so that each one is soaked for a quarter of an hour. It is then transferred to the bottle washer, a wheel with eight bottle-holders, with a revolving brush to each, that enters the bottle directly it is in position. These brushes make 300 revolutions a minute. The wheel holding the bottles is also pivoted over a tank filled with water, so that four of the bottles are always under water. On emerging, another brush cleans the outsides to remove labels, and they are then automatically ejected on to a strainer. The machine makes four revolutions a minute, which is found to be an easy rate for a beginner, but it can be made to travel faster, as soon as the attendant can place the bottles more quickly.

An appliance for aërating and mixing yeast consists of a tinned copper vessel, at the bottom of which there is a wheel formed of six copper tubes of different lengths, the ends of which are all bent sideways in the same direction. Pure sterilised air, at a pressure of from 7 lb. to 14 lb. per square inch, is forced into these pipes, first passing through a filter at the side of the vessel. The exhibitor says that the volume of yeast in the vessel is at least doubled, as well as being thoroughly mixed, and that by the use of this aërated yeast, from one to three days are saved in the fermentation, and that a better beer results. A similar apparatus, consisting merely of a copper pipe with stop cock and small air filter at the top, and at the bottom the wheel, protected by a cage, is used for mixing the wort in the working backs. This machine, like the other, is entirely of tinned copper.

Another useful machine is for labelling bottles. In this the labels are in a receptacle below, and the paste in one above; the latter has small holes at the bottom, through which the paste exudes. The paste box is brought down to the top label, and then raised by a foot lever; whilst the box containing the labels falls with a spring as soon as the bottle is placed on it, leaving the upper label adhering to the bottle.

Messrs. Pfaffenberger say that next to the Victoria refrigerator their greatest novelty is a machine for repitching the insides of barrels and for removing the old pitch. It is called "l'Incomparable," and they claim that by its use a hundred barrels can be treated per hour, against twenty when the usual hand process is adopted, also that the work is done more thoroughly and that the pitch is applied more evenly, though less is used. It consists of a covered tank on wheels with a fire-box underneath, and a pump by means of which the melted pitch at a temperature of 480 deg. to 570 deg. Fah. is forced through a vertical tube with closed top, but pierced with a number of small holes. The barrel is placed on a ring which surrounds this pipe, so that the latter enters the bung-hole. The ring is connected by levers with the handle of the pump, so that it cannot be worked unless the ring is pressed down by the weight of the barrel. This prevents the ejection of pitch from the tube, when it is not covered by the barrel. The old pitch is melted by the fresh hot pitch, and flows back into the tank to be reheated. The ring on which the barrel rests is pivoted in the centre, and five or six strokes of the pump, whilst ring and barrel are slowly turned and make one complete revolution, are sufficient to remove the old pitch and to spread a thin and even layer of new. The exhibitors maintain that by the use of this machine not only can barrels be treated at much greater speed, and with a great saving in pitch, but that accidents to workmen and burnt barrels are rendered nearly impossible.

Messrs. J. Pagny and Co., of Saventhem, show appliances for drying malt, including models of complete hot-air apparatus. Their speciality is the manufacture of lattice work of iron wire, and of narrow strips of flat iron, for drying floors. Instead of these, in positions where greater strength is required, they recommend a floor made of straight galvanised rods ⅜in. or more in diameter, set at any required distance apart, and joined at intervals of 1¼in. to 3in. by a much finer wire. The latter only is twisted, and the larger wire, not having been weakened by bending, is stronger than if woven, thus giving a flooring of greater strength for the same weight of metal, besides one which offers less impediment to the free passage of the hot air, than a floor made of woven material.

At an exhibition held in Quentin Metsys' native city we might reasonably expect to see many examples of the blacksmith's art; for the Antwerpers are still proud of their skill at the forge. Unfortunately, the display of decorative wrought iron work is not great, and most of those who have exhibited have contented themselves with copying ancient locks and hinges, or the celebrated fountain at the back of the cathedral, instead of sending in original work. In this class, the exhibit which has met with most admiration is a grape vine, shown by M. Edouard Vosters, of Arendonck. The stem, leaves, grapes, and tendrils, are all cleverly copied, and naturally and gracefully arranged. The same exhibitor also shows a bough of a cherry-tree with leaves and fruit, which, like the vine, is entirely forged work.

M. Pierre Tavernier, of Ghent, has a good selection of art ironwork—it adjoins the exhibit of M. Vosters, in a side passage not easy to find. The principal pieces are a staircase railing and a lamp pedestal, both of beautiful workmanship, and apparently of original design.

Another interesting exhibit which might easily be overlooked is the "warning barometer"—*baromètre-avertiseur*—shown by Messrs. Harze and Closset, of Brussels. This instrument is intended to give warning of sudden falls in the barometer, and is meant chiefly for use in the offices of mine managers. It consists of two aneroid barometers, connected with a clock, and so arranged that one shall be free to work in the usual way, whilst the finger of the other is held electrically, and only allowed to move during the first five minutes of every hour. The instrument will sound an alarum if the difference is more than $m$ in $n$ seconds, the values of $m$ and $n$ being decided according to the locality, and the rapidity of a barometrical fall which may be considered to indicate danger in the underground workings. In the apparatus exhibited the alarum is rung when there is a fall of $\frac{1}{25}$in. per hour.

North's Portland Cement Works, whose concrete bridge was described and illustrated in The Engineer of June 15th, page 520, show samples of concrete and briquettes. A concrete testing machine exhibited at their stand is made by Messrs. Richter and Co., of Dresden. In this machine, the strain is put on by shot which fall one by one into a bucket. Directly the briquette breaks, the bucket falls and touches a trigger which shuts off the slide, so that the exact weight on the lever is shown by the shot in the bucket. They also exhibit blocks, gutters, &c., in concrete, and various descriptions of bricks and tiles.

Tiles are also shown by the Pottelberg Company of Courtrai, who manufacture several special forms. One of these is a tile intended for ceilings, and shaped so that it fits in between the bottom flanges of two joists. Another form of tile is intended for use on angle iron purlins 14½in. apart, no wooden laths being required.

Belgian civil engineers have a separate exhibit, consisting chiefly of projects. Some of these are for turning Brussels, Bruges, and other inland cities into seaports by the construction of ship canals. Several others are for improving the river Scheldt, and more particularly that part of it opposite and just below Antwerp, and for utilising the land on the opposite side, called the Tête de Flandres. The most important set of projects are by M. Alph. Müllender, of Liége. They comprise an underground electric railway for Brussels, another under the Scheldt, a large iron-lined tunnel under the same river intended for foot-passengers and carriages, and a proposed new town on the Tête de Flandres. He also shows a full-sized model of the front of a tunnel formed of cast iron rings, like those of the South London Railway. It is 10ft. 6in. diameter, and the front of an electric locomotive is shown in it, to indicate the space it would occupy. Mr. J. H. Greathead, M.I.C.E., has worked with M. Müllender in these projects, which are now under consideration by the Belgian Government. The river at Antwerp makes a wide bend, the city being on the concave side, whilst the opposite shore has no docks, no important buildings, and is from a commercial point of view hardly utilised. English visitors are very surprised at this, and still more so on being told that the reason is because it is in a different province. Could we imagine Liverpool merchants refusing to invest money in Birkenhead unless it were transferred from Cheshire to Lancashire, or Greenwich boycotting the Isle of Dogs unless the Government agreed that it should form part of Kent? Yet this is the case with the Tête de Flandres. It is in the Province of East Flanders instead of in that of Antwerp, and Antwerp capitalists would sooner invest their money in the Congo than in the neighbouring Province. Bridges have frequently been proposed from Antwerp to the opposite side, but have always been opposed by the shipping interest, so that passengers from Antwerp to Ghent, Bruges, or Ostend, have first to cross the river by a ferry. A tunnel would certainly solve the difficulty, and enable railways from the west to have a terminus in the city, whilst it does not seem likely that such a splendid site for docks will remain unoccupied much longer, even if the work has to be done with foreign capital. One difficulty appears to be that of the fortifications. Three times this century the ramparts of Antwerp have been demolished, and reconstructed at a greater distance from the centre; and even now there are many who cannot see that with modern artillery, ramparts are of no use for the protection of a large city, which must rely on its isolated fortresses. Antwerp is surrounded by a ring of these, but Belgian military engineers say that larger ones are required at a greater distance from the city; so that if the course of the Scheldt is to be rectified and the Tête de Flandres utilised, it would seem that the present would be a suitable time for carrying out these undertakings. Any rectification of the Scheldt must necessarily take land from one province and add it to the other; but whatever increases the commerce of Antwerp is beneficial to the whole of Belgium, and it is to be hoped that no local jealousies will be allowed to stand in the way of the improvements which are being advocated by M. Müllender and others.

An exhibitor whose products are to be seen in several different parts of the Exhibition is M. Achille Legrand, of Mons, probably best known in England as the constructor of the rails, trestles, and rolling stock for the single-rail, or Lartigue railway, from Listowel to Ballybunion. His exhibits at Antwerp comprise different descriptions of portable railways, with switches and other accessories; locomotives and carriages for various kinds of produce, as well as tip-trucks and other appliances for contractors. He also shows plant of a more permanent character for the Congo Railway. In M. Legrand's system of portable railways, no bolts or wedges are required in putting each length together. The sleepers—which are of rolled steel, usually channel section—have clips riveted on, into which one side of the bottom flange of the rail fits; and these clips take the inner and outer side of the rail alternately. Thus, a length consists of two rails—usually 14 lb. or 18 lb. per yard—three sleepers with the clips on the outside, and three with them on the inside. There are no loose pieces except the fish-plates and bolts, and when once erected, the former are usually left fixed to one end. In putting a section together, the sleepers with outside clips are laid parallel and at their proper distance apart; the others are placed between them, but diagonally. The rails are then put in place, with the flange entering the outer clip, and the sleepers bearing the internal clips are then driven into position with a hammer. Where the traffic is comparatively heavy, the inner clips reach to the top of the web of the rail, and are bolted to it, the outer ones simply taking the flange as described above. In another variation of the same system, where there is no difficulty about riveting, and the sections do not require to be taken apart after they have once been put together, both inner and outer clip reach to the top of the web to which they are riveted. This gives a line capable of standing a good deal of rough usage without getting out of gauge.

The most extraordinary boiler at the Exhibition is that shown by M. G. Nechelput, of Ecaussines d'Enghien, in the grounds adjoining the Congo Section. The furnace is formed of an iron box ⅛in. or $\frac{3}{16}$in. metal, lined with firebrick. In this a series of steel tubes is caused to revolve. Water which has been heated almost to boiling point by the waste heat passing from the furnace to the chimney, is allowed to enter these tubes, and immediately vaporised.

The system is of course that of Maughan's "Geyser," except that this application of the idea of revolving tubes seems to be new. These tubes, as well as the connecting pieces on either side, are made of ¾in. steel plate. The exhibitor considers that in letting the tubes revolve, he prevents any of them from being subjected long to the fiercest heat of the furnace, and thereby adds considerably to their durability. He also maintains that a dangerous explosion would be impossible, as the quantity of steam at any time in the boiler is so small. A 30-horse power boiler occupies a surface of 3ft. 3in. square, and stands 6ft. 6in. high from the bottom of ashpan to top of feed-water heater; its total weight is 24 cwt. I saw the boiler pressure raised from 150 lb. to 250 lb. in a few minutes; but there was no means of ascertaining whether it would keep this pressure when supplying steam to a 30-horse power engine in full work, though the exhibitor assured me that it would do so easily.

## IS OUR IRON TRADE DECAYING?

In the *Times* appeared recently a somewhat sensational article on "The Decay of the British Iron Trade." The article was written in the most pessimistic spirit. The author was impressed with the belief that our trade was in an exceedingly bad way, and the only remedy he could suggest was a lowering of railway rates or the development of canals. It has been said, however, that it is possible to prove anything by figures, and the article in question was nothing if not statistical. A comparison was drawn between 1883, when the iron trade of Great Britain had reached its zenith, and other years, such, for example, as 1893. The figures were sufficiently startling to induce inquiry into their accuracy. One example of the result of the inquiry is sufficient. 1883 was credited with the production in round numbers of about 14,000,000 of tons. Now in 1893 there was produced in Great Britain 6,976,990 tons of pig iron, according to one authority, which we shall name presently. Here is a tremendous falling off, to all appearance; as nearly as possible, one-half as much made in 1893 as in 1883. But those who know something of the iron trade, are aware that no country under the sun ever made 14,000,000 of tons of iron in one year. As a matter of fact, the returns of the British Iron Trade Association show that in 1883 not 14,000,000 of tons, but 8,529,300 tons of iron were produced in Great Britain. The writer in the *Times* quietly added together the manufactured iron and steel and the pig iron, thus crediting the year with the same iron twice over. The manufactured iron and steel were made out of the pig iron. Treating 1893 in the same way, we have a total of 11,374,769 tons—a set of figures which of course convey a totally erroneous impression.

In order to arrive at an accurate idea of the position of the iron trade of this or any other country, attention must be confined to the production of pig iron and the quantity in stock, and to these things only. Mere weights cannot go beyond these. Either the trade is progressing or not, or is at a standstill. If it is getting on, the production of pigs will increase. If it is not, the production of them will diminish. The quantity in stock at the end of each year must not be overlooked. If stocks do not increase, then clearly we have been able to sell in the raw or manufactured state all the iron made. If they augment, then more has been produced than could be sold. In this way no doubt an idea of the position of the trade may be obtained, but to get a complete knowledge of its position the question of price must not be ignored. In a general way it may be said that the *Times* article is wholly misleading. The year 1883 was abnormal in various ways. It is, of course, true that other nations have greatly developed their means of production; but it does not in any way follow that because Belgium, France, the United States, and other countries can make pig and rails and such like, that we must be ruined. The demand for manufactured iron has grown to enormous dimensions. It would have been impossible for Great Britain to have gone on supplying the world, and there is no good reason now why we should not continue to do our share. We have already had something to say concerning the Belgian iron trade. That, like the trade of this and all other countries, has its good and its bad times. If we compare the progress of events in the United States with those of the trade in this country, we shall see that America has apparently far more cause for alarm than we have, yet we suppose that no American who is conversant with the subject would dream of talking of the "Decay of the American Iron Trade."

The annual report of the American Iron and Steel Association has just been issued. The figures cannot be minutely accurate, any more than are our own; particularly as regards manufactured iron and steel. The principal data are given in the accompanying table:—

| | U.S. America. | | Great Britain. | |
|---|---|---|---|---|
| Gross Tons. | 1892. | 1893. | 1892. | 1893. |
| Coal produced ... | 160,115,242 | 162,814,977 | 181,786,871 | 164,325,795 |
| Iron ore produced | 16,296,666 | 11,587,629 | 11,312,675 | 11,203,476 |
| Iron ore imported | 806,585 | 526,951 | 3,780,503 | 4,065,864 |
| Pig iron produced | 9,157,000 | 7,124,502 | 6,709,225 | 6,976,990 |
| Pig iron in stock | 506,116 | 662,068 | 872,095 | 868,730 |
| Bessemer steel ingots ... ... | 4,168,435 | 3,215,686 | 1,500,810 | 1,493,354 |
| Bessemer steel rails ... ... | 1,537,588 | 1,129,400 | 535,836 | 579,386 |
| Open-hearth steel | 669,889 | 737,890 | 1,418,830 | 1,456,309 |
| Total steel production ... ... | — | 4,019,995 | — | 3,049,663 |
| Coke produced, net tons... ... | 12,010,289 | 9,477,580 | — | — |

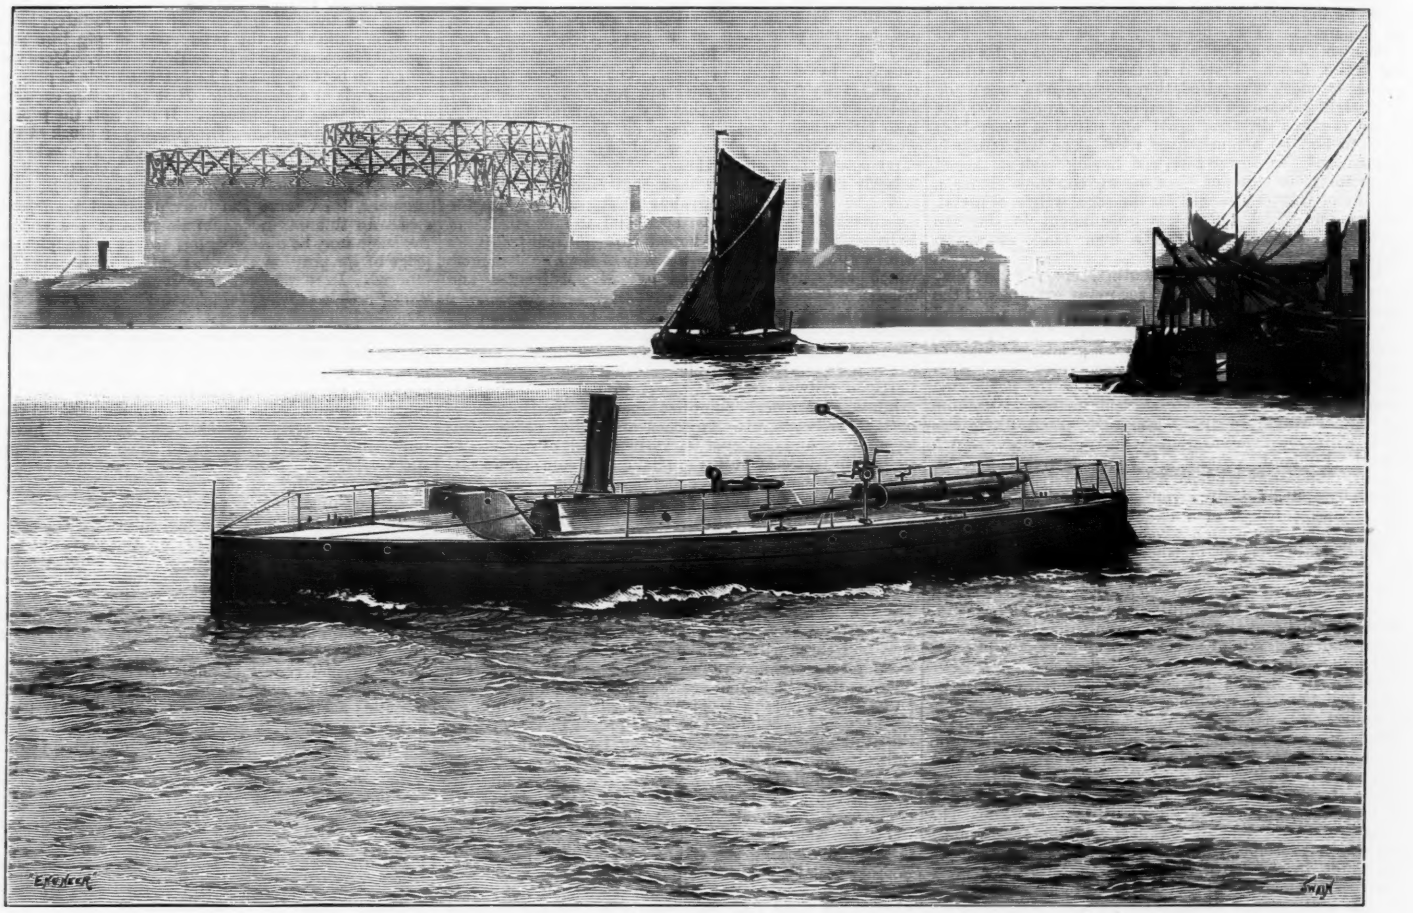
Here it will be seen that while the production of pig iron in this country was in 1893 greater by 267,000 tons than in 1892, it fell in America by no less than 2,033,000 tons. Our American contemporary, the *Engineering News*, commenting on these figures, says: "The shipment of iron ore from the Lake Superior region in 1893 amounted to 6,060,492 tons, against 9,069,556 tons in 1892, a decrease of 3,009,064 tons from this region alone. The decrease noted in pig iron productions was almost entirely in the second half of 1893; the decline in that half-year amounted to nearly 44 per cent. The production for the first half of 1894 was but slightly in excess of that of the last half of 1893, and the year ending June 30th, 1894, shows the lowest production of pig iron since the dull year of 1885." This does not look as if the United States iron trade was enormously prosperous or progressive.

It must not be forgotten, however, that the price of iron must be considered as well as the quantity. Assuming that gold is a metal with which pig iron is exchangeable, it is a matter of importance whether we get half an ounce of gold or a larger or smaller quantity for a ton of pig iron. The price of iron fluctuates in a very curious way, and seems to be more affected by what the purchaser will give for it than by the cost of production. It is certain at all events that the cost of making a ton of pig iron could not have been much more a few years ago than it is now, but the difference in prices has been very considerable. The report from which we have already quoted gives the following table of prices:—

| Articles. | 1873-9 Dols. | | 1884-5 Dols. | 1891-4 Dols. |
|---|---|---|---|---|
| Old iron T-rails, at Philadelphia ... | 25·18 | 22·05 | 19·48 | 16·43 |
| No. 1 anth. foundry pig, at Phila. ... | 18·40 | 17·52 | 15·75 | 14·52 |
| Gray forge pig iron, at Philadelphia... | 15·82 | 14·52 | 13·54 | 12·73 |
| " " Lake ore, at Pittsburg ... | 15·78 | 14·06 | 12·81 | 11·77 |
| Bessemer pig iron, at Pittsburg ... | 18·85 | 15·95 | 14·37 | 12·87 |
| Steel rails, at mills, Penna. ... ... | 31·75 | 29·92 | 30·00 | 28·12 |
| Steel billets, at mills, Pittsburg ... | 30·52 | 25·32 | 23·63 | 20·44 |
| Best refined bar iron, store, Phila. ... | 2·05 | 1·90 | 1·87 | 1·70 |
| Puddle bar iron, Pittsburg ... ... | 1·85 | 1·71 | 1·64 | 1·50 |
| Wire nails, per 100 lb., Chicago ... | 2·51 | 2·05 | 1·70 | 1·49 |

The ton here is the English ton of 2240 lb. Bar iron is rated at so much per 100 lb. Here we have a considerable drop in prices. Seeing then that there is both a fall in quantity and in price, it would be a very easy matter for the writer in the *Times* to prove that the United States iron trade is decaying. Precisely the same process must be applied to that of all other nations, and thus on a mountain of figures might be founded a story of national disaster sufficiently appalling to awe the stoutest heart. We see no reason, however, to assume that the iron trade of Great Britain or that of the United States is decaying. The demands made for work by the furnaces and mills of both countries are not easily satisfied. Not many years have elapsed since an order for 30,000 tons of rails would have filled the books of a large mill for a year. Half the quantity would have delighted the soul of any rail maker in this kingdom. Now, such an order barely suffices to keep a place going for a month. When complaint is made that trade is bad, it must not be forgotten that bad as it

## SECOND-CLASS ALUMINIUM TORPEDO BOAT FOR THE FRENCH NAVY.



is, it would have represented a period of feverish excitement with mills running night and day as hard as they could be driven but a few years since.

As to the suggested remedy—the reduction of railway rates and the development of railways—it is not necessary to say much here. The subject is one of colossal dimensions. It may be worth while, however, to say a word of warning. The discussion of such railway questions cannot be done to advantage except by those who understand very clearly what the difficulties are that the railway companies and their servants have to overcome. Thus, for example, if a company has already more traffic than it can deal with, a reduction in rates could do nothing to help the trader. As for the assertion made so freely by those who know least of the facts, that the glut of traffic and crowding of lines is due to gross mismanagement, it is enough to say that English traffic managers presumably know their business better than those whose acquaintance with the working of railways is obtained while travelling in passenger trains. An amusing instance of the mistakes that can be and are made through ignorance was recently supplied by an article in a daily contempory advocating the development of a canal between London and Birmingham. It was sadly admitted by the writer that the locks would be a great drawback; but he cheered up suddenly on remembering that in Belgium there is no trouble with locks on the canals. Lifts are used in that country, why not in England? The writer seems never to have been in Belgium, or else to have forgotten that it is for the most part an ideal country for canals, being dead flat; and as for lifts there is only one, that at Fontenette.

---

## AN ALUMINIUM TORPEDO BOAT.

Ten tons with steam up and coal in the bunkers; twenty and a half knots speed; 300-horse power. Ten years ago—perhaps five years ago—the man who suggested the possibility of producing a boat which could live in a sea and satisfy the conditions embodied in the first lines above would have been regarded as a lunatic by those who had not watched the progress of events. On Saturday last Mr. Yarrow demonstrated on the Thames the possibility of producing such a vessel, when, with a small party of guests on board, he ran an aluminium torpedo boat, which he has just completed for the French Government, from Greenwich Pier to Crossness and back. The boat which has not yet received either a name or an official number, is the largest vessel yet built of aluminium. Indeed, she is the largest structure of any kind yet produced in that metal, a small yacht and an arctic boat, recently illustrated in our columns, being her only predecessors. The torpedo boat is of the second-class. She is 60ft. long, and 9ft. 3in. beam. Thus she has 9in. more beam than the English 60ft. boats, a most important improvement in many respects. The object of what is termed a second-class torpedo boat is to be carried on the deck of large men-of-war, to be lowered in the water and to act, when necessity requires, as a scout to watch the movements of the enemy's torpedo boats, or for the use of the ship for landing and embarking the officers. The ordinary armament of a second-class torpedo boat consists of one or two machine guns placed forward and a torpedo launching tube aft.

It is self-evident that lightness of construction is of paramount importance in craft of this kind, not only because reduced displacement secures increased speed, but, considering that the boat has to be lifted and lowered by the tackle available on board the ironclad or other vessel, it is clear that the weight to be handled should be reduced to a minimum. Moreover, as these boats are placed high up on a ship's deck, any reduction of top weight increases the stability of the ship to which they are attached. In the English Navy a large number of these second-class torpedo boats is used to form part of the standard equipment of all men-of-war. The French naval authorities, however, up till last year had not adopted them, and, as they were desirous of introducing them into their Navy, they invited tenders for the best torpedo boat of this class which modern improvements enabled constructors to build, to serve as a type to be followed in the future. The primary conditions imposed were good sea-going qualities and lightness, combined with the highest obtainable speed. The proposal submitted by Messrs. Yarrow and Co. was the one accepted, as they were prepared to guarantee a higher speed and lighter weight to be lifted than any other firm, mainly in consequence of having determined to adopt aluminium for the construction of the hull. The boat illustrated is the first aluminium vessel built for the French Government.

Comparatively little has hitherto been known about aluminium as a structural material, and before adopting it Messrs. Yarrow and Co. carried out a series of elaborate experiments on the metal to obtain information. The great and uniform success of this firm in all their ventures is largely due to the elaborate system of experimenting carried out at Poplar. The trials of aluminium referred to its stiffness, best working temperature, corrosion, &c. It was found, in the first place, necessary to alloy the metal, by which its tensile strength was raised from 9 tons per square inch to about 18 tons. The alloy is mainly 6 per cent. of copper. As regards stiffness, &c., a general result was arrived at. All scantlings were increased 25 per cent. over that allowed for steel, and as aluminium weighs about one-third of steel, it follows that a reduction of about one-half was effected in the weight of the hull, which was reduced from about four tons for steel to about two tons for aluminium. In order to arrive at some precise information concerning corrosion, two aluminium plates were accurately weighed, and then secured on the sides of a wooden coppered sailing ship, the copper being removed and replaced by the aluminium. This ship made a voyage round the world, then the aluminium plates were removed, weighed, and found to have suffered no appreciable loss. The great foes to aluminium are alkalies, which attack it powerfully, and heat. It fuses at a moderate heat, and loses much of its strength at comparatively low temperatures. In the case of a torpedo boat there is no trouble incurred in avoiding both sources of risk. No plates cr angles were touched by the fire; everything was bent cold. The frames are a little closer together than they would be if of steel. The extra cost of material in the use of this particular boat being £1000 as compared with that of steel. In return there is a saving of about two tons in weight and a gain of about 3½ knots in speed over vessels of the same class and dimensions in the British Navy which steam under the like conditions at 17 knots. The boat is built in the usual way, and triple-riveted with aluminium rivets. Her machinery consists of a set of triple expansion engines, driving an aluminium bronze propeller at 580 to 600 revolutions per minute. These engines are balanced without bob weights, on Mr. Yarrow's principle, at two points only, the balance weights being fitted at properly calculated angles to the cranks. The boiler is of the ordinary Yarrow water-tube type.

The official trial took place on the 20th of September, the French Government being represented by a Commission, of which Captain L. Clerc was the president. We give below a copy of the official report of the trial:—

*Official Trial of Aluminium Second-class Torpedo Boat for the French Government by Yarrow and Co. Dimensions, 60ft. by 9ft. 3in.*

The trial consisted of a continuous run of two hours' duration in the estuary of the Thames. Weather, calm; number of persons on board, seventeen; total load on trial, three tons.

| No. of run. | Steam in boiler. | First receiver. | Second receiver. | Vacuum in condenser. | Air pressure in stokehold. | Revolutions per minute. | Time on knot. | Speed. | First means. | Second means. | Mean of means. |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | in. | in. | | M. S. | | | | Knots. |
| 1 | 185 | 72 | 12 | 24 | 2½ | 600·36 | 2 42 | 22·222 | 20 893 | | |
| 2 | 185 | 72 | 12 | 24 | 1¼ | 598·80 | 3 4 | 19·565 | 20 721 | 20·807 | 20·503 |
| 3 | 175 | 72 | 12 | 24 | 2⅜ | 593·40 | 2 45 | 21·877 | 20 412 | 20 566 | |
| 4 | 175 | 62 | 11½ | 24 | 1½ | 578·16 | 3 10 | 18·947 | 20 187 | 20 299 | |
| 5 | 180 | 65 | 11 | 24 | 1½ | 586·80 | 2 48 | 21·428 | 20·496 | 20 341 | |
| 6 | 185 | 70 | 12¼ | 24 | 1¾ | 591·48 | 3 4 | 19·565 | | | |

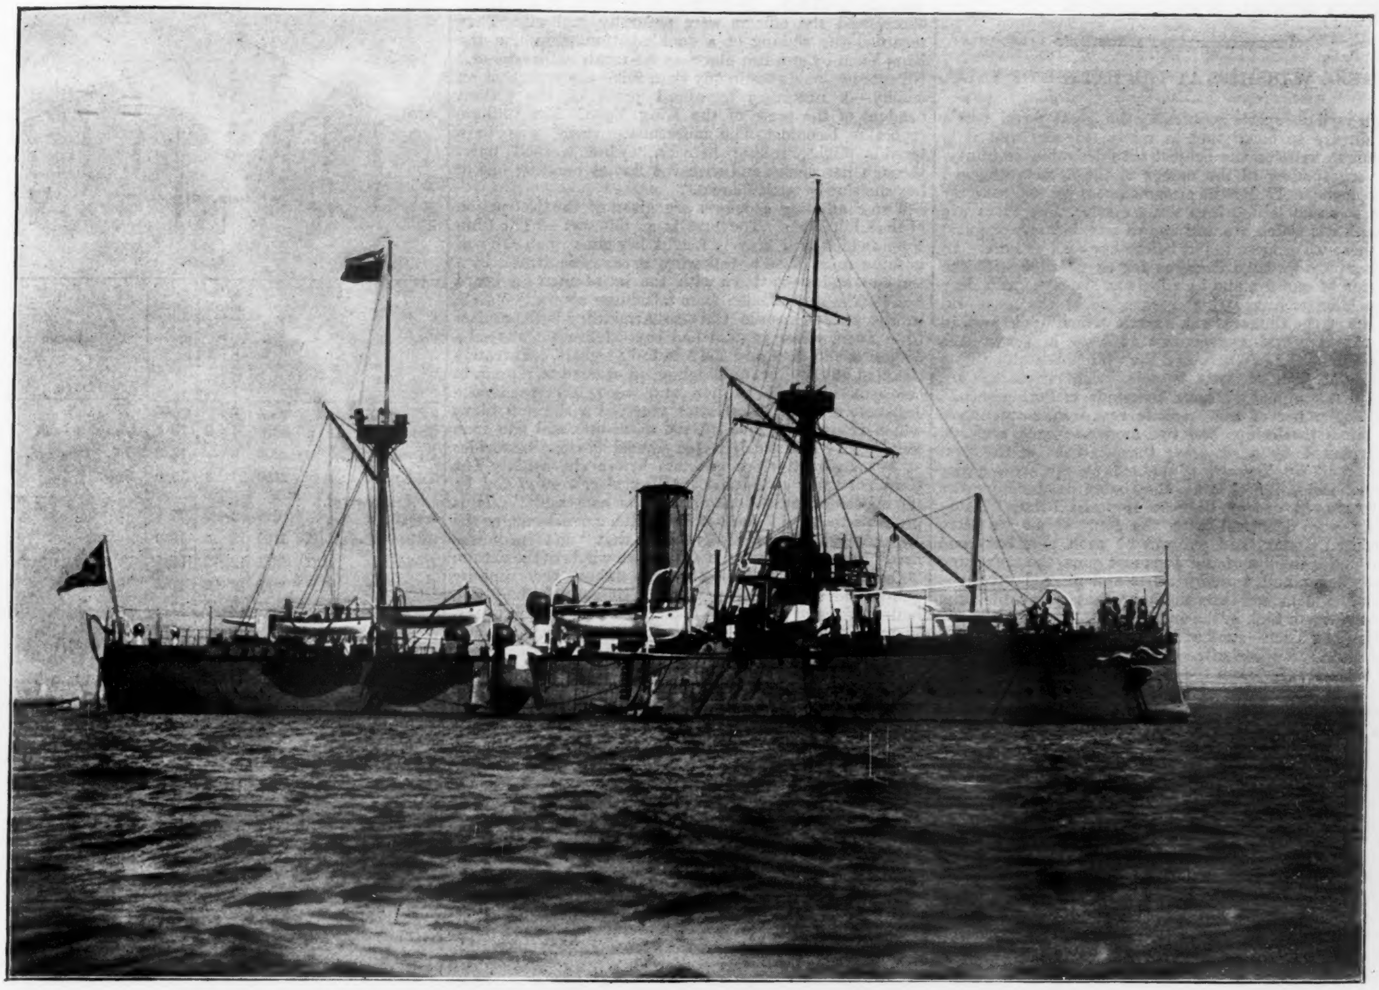
During the trial of two hours' duration the engines made 70,948 revolutions, being at the rate of 591·2 revolutions per minute, corresponding to a mean speed during the entire run of 20·558 knots per hour. The boiler—Yarrow's patent water-tube—made ample steam without priming, and the engines worked without any heating. The vibration was very slight, and not appreciable.

During all the trials of this boat, the absence of vibration and of noise in the engine-room has been most noteworthy. On Saturday she was run at various speeds from dead slow up to the highest attainable, and at none was the slightest vibration to be felt in any part of the boat forward, aft, or amidships. The only thing of the kind perceptible was a species of purring thrill. Part of this is no doubt due to the construction of the engines; but much remains to be explained by the metal. Although aluminium is in some forms one of the most sonorous in existence, in the shape of a torpedo boat it is wanting in that resilience and vibratory stiffness peculiar to steel. This largely explains the comparative silence of the engines. In a thin steel hull every sound is magnified, in the aluminium boat it is deadened—the new metal behaving apparently very much like wood. Nor is this silence without its value. Such a boat as this of which we write might be able to creep alongside an enemy and take him unawares, where the ordinary boat would be detected in the stillness of a night by the clank of its machinery.

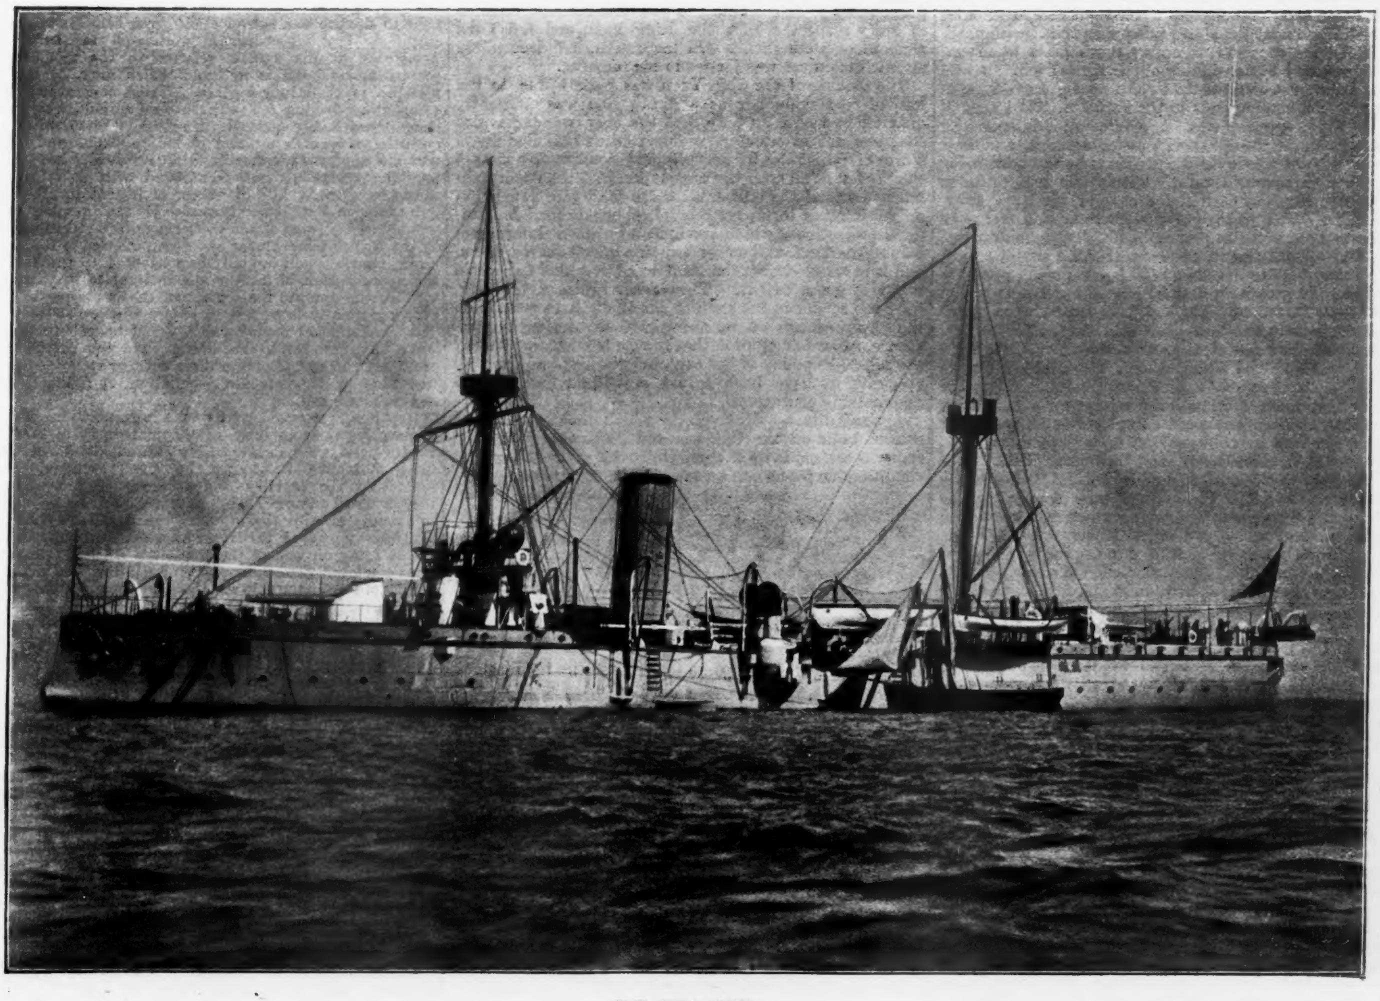
Beyond all question Mr. Yarrow has achieved a remarkable success. Many wise men shook their heads when he suggested the use of aluminium, and did not hesitate to

# UNARMOURED CHINESE WARSHIPS

(*For description see page 294*)



THE CHING YUEN



THE CHIH YUEN

say he was courting failure. The result has, however, more than justified him; he has succeeded in producing the best torpedo boat of the size that has ever been built. It now remains for the makers of aluminium to improve their processes and cheapen their material, so that the use of the new metal may be widely extended.

## CHINESE WARSHIPS AT THE BATTLE OF YALU.

The various reports concerning the great naval battle of Yalu are so conflicting in many respects that it is difficult to write on the subject with desirable certainty. The very spelling of the names of the vessels engaged is perplexing. Under the circumstances we can scarcely hope to avoid falling into some error. But there are certain facts which are well known and beyond dispute, and these we propose to put before our readers here. In another page we have dealt as far as possible with the question of gun-fire and its effects as displayed at Yalu.

We have engraved this week some of the most important of the Chinese war vessels which took part in the recent naval engagement at Yalu in Corea—the King Yuen and Lai Yuen, and the Chih Yuen and Ching Yuen—two pairs of sister vessels. The engravings are from photographs by Messrs. Symonds, of Portsmouth.

In September of 1887, a little squadron, consisting of two small battleships and two moderate-sized cruisers, accompanied by a sea-going torpedo boat of the first class, built by Yarrow, assembled at Spithead under command of Admiral Lang, they being destined for the reinforcement of the Chinese Imperial Fleet. These vessels were identical with the four which we have illustrated to-day, and one out of each pair has gone down under the fire of the Japanese guns, the remaining vessels being hulled many times and pierced upon the water-line, demonstrating the important part which the whole of them took in the engagement.

The King Yuen—sunk at Yalu—and the Lai Yuen, two small twin-screw barbette ships, partially armour belted and intended for coast defence, but capable of making extended passages at sea, were laid down for the Chinese Government by the Vulcan Company at Stettin, and were launched, the first on the 3rd of January, 1887, and the last on the 25th of March, 1887. They were completed in the summer of 1887, and left England, as mentioned above, in September of the same year.

The armour was compound, and consisted of a belt for protection of the engine and boiler-rooms from 2ft. above the water-line to 4ft. below it, and was 9½in. to 5¼in. thick. This belt was terminated and reinforced by transverse bulkheads 8in. thick. A protective deck 1½in. thick extended over the belt, the extremities of the vessel being protected by an armoured deck, sloping down, of 3in. in thickness. Their heaviest guns were coupled in a pear-shaped redoubt forward of the funnels, with 8in. of compound armour, whilst a strong steel shield extended over this barbette.

There was a conning tower abaft and above the barbette protected by 6in. armour. A double bottom extended for about two-thirds of the length of the ship, which was divided into sixty-six separate water-tight compartments, of which those next the ship's side were packed with cork. We shall have occasion to notice these facts when we allude presently to the sinking of the King Yuen.

The armament consisted of two 21 centimetre—8¼in.—Krupp breech-loading guns in the barbette, two 15 centimetre—5·9in.—guns of the same description in sponsons on the beam amidships, seven machine guns, and four Schwartzkopff torpedo dischargers, one in the bow under water, and three above water. There was one military mast. Ammunition carried for each of the large guns, 50 rounds. The principal dimensions, &c., were as follows:—Length, 270ft.; breadth, 40ft.; extreme draught, 16ft. 6in.; displacement, 2850 tons. The engines were triple expansion, to develope 3400 horse power, giving a speed of 15½ knots with natural draught and a speed of 16½ knots with forced draught. The boilers were cylindrical and four in number. The coal storage 325 tons.

The two twin-screw steel-protected cruisers, Chih Yuen—sunk at Yalu—and Ching Yuen, were laid down at Elswick in October, 1885. The first was launched on the 29th of September, 1886, and the second on the 14th of December, 1886. They were completed, and went out with the two ironclads built at Stettin, in September, 1887.

They had a turtle-back steel armoured deck from 2in. to 3in. thick, and a double bottom beneath the machinery. Two 8in. 12-ton guns were coupled in the bows upon a Vavasseur mounting, which was protected by 12in. of steel, and a protective shield. A third 8in gun was at the stern, whilst a 6in. 4-ton gun was sponsoned out on each broadside. They also carried seven 57 mm., two 47 mm., and eight 27 mm. quick-firing guns, six machine guns, and four torpedo tubes. The dimensions, &c., were as follows:—Length, 250ft.; breadth, 38ft.; draught, 15ft.; displacement, 2300 tons. The engines were triple-expansion, designed to develope 5500-horse power, and the estimated full speed was 18 knots. Coal capacity 450 tons.

A graphic description was given by the Flag Lieutenant of the Japanese Admiral of the way in which the King Yuen was fought by her Chinese captain, and her subsequent going down. The error which was made by the Japanese in mistaking her for her sister-ship, the Lai Yuen, is obvious. We have necessarily transposed the names. The report ran as follows:—"After a time the Chinese Admiral apparently became desperate. His formation was broken, and two or three of his ships advanced against us at full speed." Apparently the King Yuen and Chih Yuen. "The fighting became furious, but our weight of metal told, and one ship, the King Yuen, was crippled in this venture. When the Chinese resumed their line formation our guns were directed upon the disabled ships, particularly the King Yuen. She had been riddled by shot and shell, and it was evident that she was sinking. The Chinese gunners worked their weapons to the last. Finally, she went down slowly stern first. Her bows rose clean out of the water, and she remained in this position for a minute and a-half before she disappeared in one last plunge. We had used no torpedoes upon her, but sank her by fair shot and shell fire. It spurred all our men to additional effort, and the officers were naturally exultant. They regarded the sinking of a double-bottom ship like the King Yuen by gun fire alone as no mean achievement." No more valuable testimony than this—the report of an enemy—is necessary to afford proof of the gallant conduct of the crew of the King Yuen. The Chinese report is laconic. The unfortunate vessel was in a terrible plight, rolling heavily, "when a shell burst through her decks, and with the flames bursting out of her she slowly settled down."

Two conflicting accounts are given of the destruction of the Chih Yuen. The first is as follows:—"The Chih Yuen, which still bravely fought her guns when she was nothing more than a wallowing wreck, was struck by a torpedo, and went down with the brave men on board her." The second, also from a Chinese source:—"Late in the afternoon, the Chinese Armstrong-built cruiser Chih Yuen, whose captain had several times displayed a disposition to disregard the Admiral's signals, deliberately steamed out of line, although again ordered to remain in the spot assigned to her, and went full speed at a Japanese cruiser. The latter received a slanting blow, which ripped her up below the water-line, and she soon foundered. But she delivered several parting broadsides at her enemy at close quarters before she sank. The Chih Yuen was so injured by the cruiser's guns and by the effects of the collision that she also sank." It is probable that the latter account is the correct one, as the Japanese admiral positively asserts that "no torpedo was fired" by any of his vessels during the whole of the action.

Only one ship, therefore, appears to have been sunk by gun-fire alone, the King Yuen. Probably she had been hulled over and over again beneath and upon the water-line, when she rolled and exposed her bottom. Her sixty-six separate compartments failed to keep her afloat. It would be interesting to know whether, in the exigencies of service during the fight, the water-tight doors had to be left open. Reports say that the pumps of all the vessels were working furiously, and this shows that the engines and boilers were intact. It is possible that the one shell particularly alluded to, which burst through the deck, after which the vessel settled down, may have got into and wrecked the engine or boiler rooms. The stoppage of the pumps would necessarily have hastened the foundering of the vessel.

Whether, however, the vulnerability of the King Yuen was due to the thinness of the protective deck over the vitals—that being only 1½in.—or to failure of the water-tight door system, or to the awful concentration of the efforts which were made to sink her, the fact remains that she did go down under gun fire alone. In this connection it may not be inopportune to quote some remarks which were made by an officer on board of her at Spithead in September, 1887. He was drawing a comparison between her and her sister-ship, and the Chih Yuen and Ching Yuen turned out by Elswick. The two latter he pronounced to be splendid and powerful cruisers, finished in every respect, whilst the King Yuen and Lai Yuen were incomplete shells. On inspection, it did certainly appear that there was justice in his remarks.

The sinking of the Chih Yuen was clearly due to the folly of employing her as a ram. She was eminently unsuited to such a purpose, and the only wonder is not that she did eventually go down when assailed by a storm of projectiles in her crippled condition, but that she floated at all after her concussion with the enemy. In later vessels of the cruiser class the solid ram bow is not only reinforced in strength by phosphor bronze longitudinal projections, which are built into the cellular mass behind the forefoot, but the armoured deck curves down, and is associated with the stem so as to stiffen the whole to a very great extent. The earlier cruisers, however, were too tender in the stem to admit of their sustaining the severe shock of ramming without serious injury. Hence, we are of opinion that the Chih Yuen was lost by the mistaken policy of her captain, who appears from all accounts to have been a rash and ill-advised, though undoubtedly courageous, sailor.

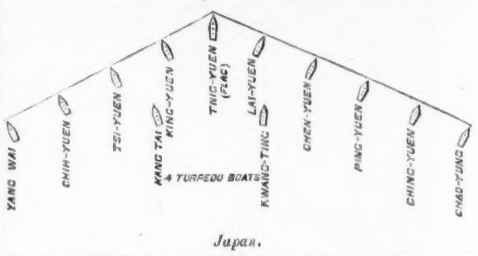
Appended is a list of vessels which took part in the action, both on the Chinese and Japanese sides, and remarks are made in the margin as to their subsequent condition, so far as can be ascertained at present:—

*China.*

| Ships. | | Displacement. | Armament Heavy | Armament Small | Speed. | Remarks. |
|---|---|---|---|---|---|---|
| *Armoured.* | | Tons. | | | Knots. | |
| Chen Yuen | P.3″ | 7430 | 6 | 8 | 14·5 | Belted. Disabled. |
| King Yuen | P.3″ | 2850 | 4 | 7 | 16·5 | Do. Sunk. |
| Lai Yuen | P.3″ | 2850 | 4 | 7 | 16·5 | Do. Caught fire; much damaged |
| Ping Yuen | P.2″ | 2850 | 3 | 8 | 10·5 | Do. |
| Ting Yuen | P.3″ | 7430 | 6 | 8 | 14·5 | Do. |
| *Unarmoured.* | | | | | | |
| Chih Yuen | P.4″ | 2300 | 5 | 23 | 18·0 | 10″ steel armour on barbette. Sunk. |
| Ching Yuen | P.4″ | 2300 | 5 | 23 | 18·0 | Do. Hulled badly. |
| Kwang Kai | P.1″ | 1030 | 3 | 8 | 16·5 | One of these subsequently said to be destroyed. |
| Kwang Ting | P.1″ | 1030 | 3 | 8 | 16·5 | |
| Tshao Yung... | ... | 1350 | 6 | 7 | 16·8 | Destroyed. |
| Tsi Yuen | P.4″ | 2355 | 3 | 9 | 15·0 | Disabled. |
| Yang Wai ... | ... | 1350 | 6 | 7 | 16·0 | Destroyed. |

And four torpedo boats.

The crushing damages that the Chinese squadron sustained are only too apparent. The Kwang Kai and the Kwang Ting, which were up the river with the transports when the Japanese appeared in sight, are the only vessels not reported to be injured, yet one of these was afterwards found on shore and torpedoed. The position of the Chinese was approximately thus, at first:—



*Japan.*

| Ships. | | Displacement. | Armament. Heavy | Armament. Small. | Speed | Remarks. |
|---|---|---|---|---|---|---|
| *Armoured.* | | Tons. | | | Knots | |
| Fusoo ... ... ... | | 3718 | 6 | 5 | 13·2 | Iron ship, old. |
| Hi-yei ... ... ... | | 2200 | 9 | — | 13·0 | Old. Disabled. |
| Tschiyoda | P.1″ | 2450 | 24 | 3 | 19·0 | New. |
| *Unarmoured.* | | | | | | |
| Akagi ... ... ... | | 615 | 2 | 2 | 12·0 | |
| Akitsuschima | P. | 3150 | 13 | 6 | 19·0 | |

| Naniwa | P.3″ | 3650 | 8 | 12 | 18·72 | |
| Takachiho | P.3″ | 3650 | 8 | 12 | 18·72 | |
| *Yoshino | P.4½″ | 4150 | 12 | 22 | 23·03 | Much injured. |

* Illustrated in our impression for February 16th, 1894.

The Sakiomaru was accidentally present in the engagement, and appears to have suffered severely if not sunk. It seems, thus, that whilst no vessels were actually lost by the Japanese, except possibly the Sakiomaru, three were either disabled or terribly injured; and, as the only reports upon their actual condition have been received from Japan, the whole truth may be much more serious than is admitted to be the case. But, clearly, China has come out of the action very much the worst.

## LORD ARMSTRONG ON SHIPS AND GUNS.

On Thursday, September 27th, the annual general meeting of the Elswick firm was held, and passed through with the brevity and calmness characteristic of these meetings. As the firm, in spite of the troubles of the past year, has been able to declare a dividend of 10¾ per cent., it is scarcely surprising that all concerned were well satisfied. Lord Armstrong in his speech referred to the moulders' and pattern makers' strikes in terms which must be far from pleasing to the labour leaders. Whilst congratulating the company on having a floating capital of sufficient bulk to carry them safely through these trade disturbances, and ensuring to them a position of independence and dignity, without appreciably affecting the dividend, he said the moulders' strike has now terminated with no other result than loss of trade, loss of wages, detriment to all cognate industries, and a large increase of the number of the unemployed. None of the great battleships recently ordered by the British Government have been allotted to the Tyne, a circumstance which can only be attributed to the fact that the apprehension of further labour troubles in this strike-torn locality damped the courage of the employers to tender at a sufficiently low price to secure a share of the orders. Thus vast sums of money which would have been spent in wages have been lost to the district, and the chief sufferers are those who seek to obtain their ends by stoppage of work instead of by dispassionate negotiation, or failing that, by impartial arbitration.

He then reviewed briefly the advances in hydraulic engineering as exemplified in the machinery of the Tower Bridge and Manchester Ship Canal, and in quick-firing ordnance as shown by the result of experiments on the rapidity and accuracy of fire. Some of the figures quoted have appeared in these columns in connection with the ordinary reports of the ship trials. The following are of particular interest:—In competition at target firing on one of the first-class English cruisers, the guns employed were 6in., weighing 6¼ tons, and firing projectiles of 100 lb.; the ship was steaming at eight knots an hour; and the range of the target varied from 1600 to 2200 yards. The best gun's crew fired 18 rounds in three minutes, and hit the target 14 times; the second crew got 12 hits out of 18 rounds, and the third 12 hits with 17. On the Royal Sovereign, a 13½in. gun, weighing 68 tons on an hydraulic mounting, and fitted with hydraulic breech-opening gear, fired seven rounds with projectiles weighing 1250 lb. in 12 minutes; and whilst the ship was steaming at eight knots an hour hit the target six times, the range varying from 1600 to 2000 yards.

Lord Armstrong, in remarking on the Chino-Japanese naval battle, said he preferred to reserve his opinion till further details were to hand, but he thought it had been clearly shown that swift cruisers, while "undoubtedly best for protecting commerce and for every variety of scouting and patrolling service, are also capable of acting with effect in pitched battles where vessels classed as 'battleships' are opposed to them."

Naval Engineer Appointments.—The following appointments have been made at the Admiralty:—Chief Engineer: Arthur J. Jones, to the Racer. Engineers: Edwin Cudlip, to the Daring; and Hamilton J. Coad, to the Hornet.

## RAILWAY MATTERS.

The Mafeking Railway was opened on Wednesday amid great festivity.

The underground portion of the Walthamstow and Epping Forest Railway will be constructed on the Greathead shield principle. This is the only line that is authorised to use either steam or electricity.

From a report recently issued, it appears that during the last ten years, in the face of an increase of 1963 miles of railway, and large additions to the train mileage and number of trains, the accidents connected with shunting and the "coupling" and "uncoupling" of trains, decreased from 29 and 341 killed and injured in 1884, to 11 and 286 respectively in 1893.

The Executive Committee of the Mansion House Association on Railway and Canal Traffic for the United Kingdom have resolved to initiate test cases under the new Act in regard to the increased rates on merchandise and agricultural produce. It has also been decided to invite the co-operation of those traders and trade and agricultural organisations who desire to avail themselves of the provisions of the Act.

The subject of street car fenders has been investigated by Mr. Mendes Cohen, Past President of the American Society of Civil Engineers, who reports to the Car Fender Commission of Baltimore, that the best devices are those including a projecting front fender and a wheel guard. A new ordinance requiring the street railway companies to use one of the improved fenders, recommended in the report, is expected to be submitted to the City Council.

The Midland Railway Company are employing 500 workmen in laying pipes for the conveyance of water to Leicester to supply their engines. Pumping engines are also being erected to pump the water, and they will be in full operation in a few days pumping the water from Wigston Junction to Leicester, a distance of five miles. The little water left in the reservoirs is rapidly diminishing, and there is still no sign of the heavy rainfall which has so long been looked for.

The running of the Highland Railway Company's trains is being somewhat interfered with by the Scotch coal strike. Owing to the impossibility of obtaining Fife coal, for the consumption of which the fire-boxes have been designed, Newcastle coal has been resorted to, with the result that the trains are, by their lateness, inflicting much inconvenience on the large numbers of people at present travelling. The caking of the Newcastle coal on bars which are so close to one another as to prevent the necessary supply of air from passing, is presumably the chief cause of the trouble.

On the opening of the line north of the Godavria of the East Coast State Railway—standard gauge—in India, the rates per mile for passengers were fixed as follows: First class, 1d.; second class, 0 50d.; third class, 0·125d. On and from January 1st, 1894, however, a fourth class—cooly class—for local booking only, was introduced on this line at the rate of 0·125d. per mile, and the ordinary third-class fare increased from 0·125d. to 0·167d. per mile. It would be interesting to see the effects of the Board of Trade requirements as to signalling, fencing, &c., on the profits of Indian railways at such fares as these.

A report just published shows that the casualties on Indian Railways during the year 1893 have decreased by 1·26 per cent. in killed and 2·78 per cent. in injured, as compared with the previous two years. The proportion of passengers killed in train accidents from causes beyond their own control was one in about 2,652,215, while passengers injured from this cause was one in 1,610,261. Taking the aggregate length of the whole Indian railway system as 18,121 miles, the train mileage run as 2,088,759 miles, and the total number of passengers travelling as 135,269,950, there were 114 killed and 268 injured, or an average of one killed in 1,186,517, and of one injured in 50,472.

For lighting their carriages, the Indian railways seem to have very fully adopted the Pintsch's system of gas lighting. In 1893 on the East Indian Railway, 56 out of 180 vehicles have been fitted with gas lamps on this system. On the Indian Midland Railway sanction has been received for lighting 225 carriages by this method, and a few carriages on the Great Indian Peninsula Railway have also been fitted with the necessary apparatus for the system. Sanction was given during the year for the substitution in the carriages of the Bombay, Baroda, and Central India Railway of Pintsch's gas system instead of oil lighting. On the Madras Railway the estimate of the gas plant and fittings was sanctioned at the close of the year 1893, and the material necessary for the introduction of gas lighting will shortly be received from England. This system of lighting costs so much less than the old oil lamps, that the Government of India have ordered that arrangements should be made to introduce the compressed gas system on State lines of the standard gauge, as soon as funds can be made available for the purpose.

The railway across the Isthmus of Tehuantepec is reported as practically completed and about to be opened to traffic. This road is 192 miles long, from Coatzacualcos, on the Gulf of Mexico, to Salina Cruz, on the Pacific. As a competitor with the Panama Railway, it would make the distance from New York to San Francisco 4325, against 6107 miles by way of Panama. This is a saving of 1182 miles in distance, and fully three days of water travel. The Isthmus of Tehuantepec has been discussed as a railway route since 1842, and in 1878 Mr. Edward Learned, of New York, completed about twenty-two miles of line, when the contract was annulled. In 1882 a contract was let to a Mexican by the name of Sanchez, who built about sixty miles of wretched road. In 1888 the Mexican Government let the contract to Edward McMurdo, of London, and on his death a new contract was made, February, 1892, with Messrs. C. C. Stanhope, of England, and I. M. Hampson and E. L. Corthell, of the United States. As the original appropriation was exhausted, a new contract was made in December, 1893, with Stanhope and Co. to complete the final forty miles of the road, and this is the contract now declared finished and completing the railway from ocean to ocean. Mexico proposes to spend about £800,000 more on harbour and terminal facilities at the two ends.

The death took place at Rouen last week of an engineer named Martin, for whom, in France, is claimed the invention of what is known as the Westinghouse brake. M. Martin took out a patent on March 10th, 1860, for a compressed air brake, which those in France consider identical with the Westinghouse brake, and anticipated also the Smith and Hardy vacuum brake, of which the improvement, patented in 1877, for utilising the steam by means of the injector for producing the vacuum was exactly similar to that brought out seventeen years before by MM. Martin et du Tremblay. At that time M. Martin tried to induce the railway companies to adopt his invention, and the Compagnie de l'Est allowed him to carry out experiments upon one of their trains. For some reason or another the experiments never came to anything, and no further attempt was made to introduce the brake. M. Martin never made anything out of his patent, and he was reduced to a state of great poverty. In 1882 the Société d'Encouragement pour l'Industrie Nationale had their attention called to the case of M. Martin, and they granted him a gold medal, together with a sum of 3000f. It may be mentioned that a continuous compressed air brake was designed and published in 1851 in England; but Westinghouse was the inventor of the real complete working brake, and the man who not only made it, but made it a working success.

## NOTES AND MEMORANDA.

In Greater London last week 3310 births and 1573 deaths were registered, corresponding to annual rates of 28·1 and 13·8 per 1000 of the estimated population.

According to a recently described patented apparatus for precipitating gold and silver from cyanide solutions, by A. H. Bell and C. Carter, the solution is made to rise up against and between movable and stationary zinc surfaces, which are kept bright by friction against each other. The particles of zinc so removed pass into the solution together with the precipitated gold and silver, which are collected in a settling chamber, and taken out at suitable intervals.

The rainfall for the six months of the recent summer at Greenwich was 12·58in., or 0·34in. below the average of forty years, and July and August were the only months in which the rainfall was in excess of the normal, but in each of these the amount measured was more than 3in. The greatest frequency of rain at Greenwich was in July, when rain fell on 19 days, and in August it fell on 16 days. During the whole summer rain was experienced on 88 days, which is, roughly, one day out of every two. In other parts of the kingdom the rainfall was generally in excess of the average, but in the Midland Counties there was a deficiency amounting to 2in. in the six months.

The following recipes for new stains for wood are given in the *Scientific American*:—A solution of 50 parts of commercial alizarin in 1000 parts of water, to which a solution of ammonia has been added drop by drop until a perceptible ammonia odour is developed, will give to fir and oak a yellow-brown colour and to maple a red-brown. If the wood is then treated with a 1 per cent. aqueous barium chloride solution, the first-named become brown and the latter a dark brown. If calcium chloride be used instead of barium chloride, the fir becomes brown, the oak red-brown, and the maple a dark brown. If a 2 per cent. aqueous solution of magnesium sulphate be used, the fir and oak become dark brown and the maple a dark violet-brown. Alum and aluminum sulphate produce on the fir a high red and on oak and maple a blood red. Chrome alum colours maple and fir reddish brown, and oak Havana brown. Finally, manganese sulphate renders fir and maple a beautiful dark violet-brown, and oak a dark walnut-brown. All the colours are said to be very fine.

An interesting paper upon the age of Niagara Falls was read at a meeting of the American Association for the Advancement of Science. Professor Spencer said that the first conjecture as to the age of Niagara Falls was made by Andrew Ellicott in 1790, who supposed the falls to be 55,000 years old. About 1841 Lyall estimated the age of the falls as 35,000 years. According to Professor Spencer the evolution of the falls was as follows:—A little stream draining the Erie basin only fell about 200ft. over the brow of the Niagara escarpment, and in magnitude was just about the size of the American Falls. This stream was not over one-fourth the present volume of the great cataract, and, consequently, was able to excavate the gorge at a much lower rate than at present. During this early history of the river the waters of the three upper lakes emptied through the Huron basin, by way of the Ottawa River. The height of the falls has advanced several times, and, owing to this change and the variation in the discharge of the water, retreat of the falls has varied greatly during changing episodes. The computations of the age have been based upon these changing conditions of elevation and downfall of the river. The first episode, as before stated, represented a small river, with a total fall of 200ft. This lasted about 11,000 years. Then fell another episode, where the height of the Falls was increased from 200ft. to 400ft., succeeded by the entire drainage of all the upper Great Lakes. At the same time there were series of three cascades, the lower gaining on the upper, until finally they were all united in one great cataract, much higher than that of the present time. Subsequently the waters were raised at the head of Lake Ontario so as to bring about the present conditions after a lapse of 17,000 years from the end of the first episode.

At the Goldsmiths' Company's Technical and Recreative Institute, Mr. George Livesey, the chairman of the South Metropolitan Gas Company, recently delivered an address on gas manufacture, being the first of a series of twenty-eight technical lectures which will be given at the institute on the subject of gas industry. Mr. Livesey, after giving an interesting history of gas production, said that gas now had fierce competition, and no monopoly as a lighting agent. It, however, not only held its own, but continued to gain ground at a most encouraging rate. Having referred to the extended uses of gas for cooking, heating, and other purposes, Mr. Livesey observed there did not appear to be scope for much improvement in manufacture, so far as turning out a better article was concerned. Most of the improvements had for some time been in the direction of a reduction of cost; in the matter of purity there was very little more that could be done. The only so-called impurity of which the public complained was what they called smokiness, or, to use their expression, "dirty gas," because in gas-lighted rooms the ceilings became blackened sooner than in rooms where gas was not used. If architects and builders would construct flues which would conduct the products of combustion away from the room, the most perfect ventilation could be attained by utilising the heat of the gas for that purpose, and the gas would not only give light, but at the same time ensure the removal of its own and of all vitiated air. After referring to the great improvement in recent years in burners and to the advantages thus given to the consumer, he stated that consumption of coal for gas-making was about 12,000,000 tons per annum in the United Kingdom, it being in London and its suburbs alone 3,250,000 tons in 1893. The maximum quantity used in one day in the depth of winter in Greater London would be about 18,000 tons, or 750 tons an hour.

In our report of the meeting of the British Association at Oxford, and the discussion on Mr. Maxim's paper, we mentioned that Mr. Maxim had found that the resistance of the air against a thin stiff plane caused to move at sixty miles an hour through it, in a direction inclined to the plane at a slope of about 1 in 8, was found to be about fifty-three times as great as the estimate given by the old "theoretical" (!) formula, and something like five or ten times that calculated from some more recent formula. Lord Kelvin now writes to *Nature*, saying:—"I had always felt that there was no validity, even for rough or probable estimates, in any of the 'theoretical' investigations hitherto published; but how wildly they all fall short of the truth I did not know until I have had opportunity in the last few days, *procul degotiis*, to examine some of the observational results which Maxim gave us in the introduction to his paper. Mr. Maxim said in his paper:—'The advantages arising from driving the aeroplanes on to new air, the inertia of which has not been disturbed, is clearly shown in these experiments.' Founding on this principle, I have at last, I believe, succeeded in calculating, with some approach to accuracy, the force required to keep a long, narrow, rectangular plane moving through the air with a given constant velocity, $V$, in a direction perpendicular to its length $l$, and inclined at any small angle $i$ to its breadth $a$. In a paper, which I hope to be able to communicate to the *Philosophical Magazine* in time for publication in its next October number, I intend to give the investigation, including consideration of 'skin-resistance' and proof that it is of comparatively small importance when $i$ is not much less than one-tenth, or one-twentieth, of a radian, and the 'plane' is of some practicably smooth, real, solid material. In the meantime, here is the result, with skin-resistance neglected: The resultant force—perpendicular therefore to the plane—is $\frac{1}{2}\pi V^2 \sin\theta \cos\theta\, la$; which is $\frac{\cos \pi \theta}{\sin \theta}$ times—or for the case of $\sin\theta = 32$, one hundred times—the old miscalled 'theoretical' result."

## MISCELLANEA.

The Physical Society will henceforward hold its meetings in the rooms of the Chemical Society, Burlington House.

A new gun-mounting for 12-pounders has been delivered at Portsmouth from Elswick, to undergo a series of trials.

The strike among the dredger-men of the Suez Canal is seriously extending. It is stated that all the dredgers as far as Ismailia have been abandoned.

The Benbow, battleship, has been absent from her station at Greenock, the Admiralty having decided to fit her barbettes with steam heating arrangements similar to those recently put on board the Rodney, battleship.

We have received the First Part of Cassell and Co.'s new "Popular Educator," revised and brought up to date. The style of the work appears of a kind eminently calculated to maintain the reputation which has been obtained in the past by this excellent publication.

The only medal awarded by the Sanitary Congress, at their recent assembly at Liverpool, for an efficient method of connecting pottery to lead, was awarded to Messrs. Doulton and Co., for their metallo-keramic joint, which we noticed in our columns some while ago.

The Bellona cruiser, recently commissioned at Devonport to take the place of the Barrossa in the Channel Squadron, has undergone her three hours' steam trial. Shortly after starting her safety valves were discovered to be leaking, although the pressure in her boilers was comparatively low. An attempt to make temporary repairs failed, and the trial was abandoned.

The Canadian Parliament has just passed an Act providing for the inspection of electricity meters. This Act allows consumers, whenever they are dissatisfied with the action or tests of the electric light contractors, to have their wires and fittings tested by an electric light inspector, upon application to the Inland Revenue Department, which has charge of the inspection under the Act. The Act also settles a question upon which there was formerly no written law, in providing that any persons discovered maliciously or fraudulently abstracting, or causing to be wasted or diverted, any electricity, shall be dealt with as guilty of theft, and punished accordingly.

It is stated by the chairman of the Water Committee of Leicester that although the need of economy in water is pressing, the service being now only from 7 a.m. to 6 p.m., there is no prospect of the water famine which has been persistently threatened by the daily papers. There is at present in the reservoirs over 100,000,000 gallons, and this may probably be reduced to 30,000,000. Besides this available supply the steps which are now being taken will amply protect the town against any disastrous consequences of the recent drought. The rainfall of this district averages 28in. In 1891 the rainfall was about 32in.; in 1892, slightly under 23in.; and in 1893, slightly under 22in.; in 1894 to the present date, about 15½in., of which less than 1in. fell in September.

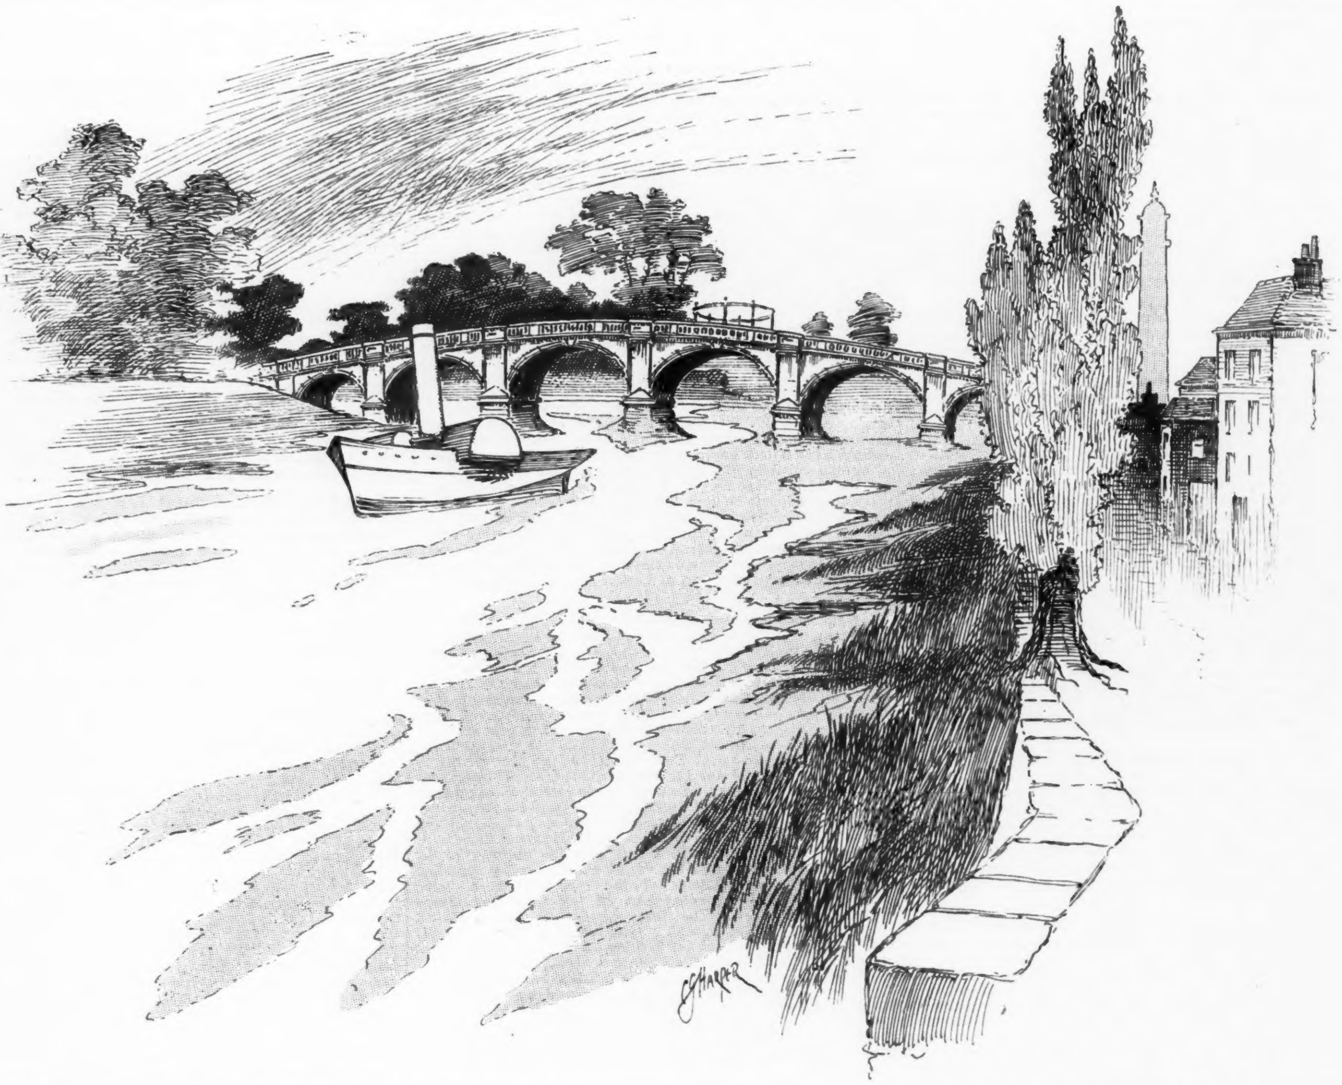
In a letter to the *Times* on the Royal Commission on Water Suppy and the river Lea, Sir John Evans says:—"In September, 1893, appeared the report of the Royal Commission on the Water Supply of the Metropolis, in which, among other things, was recommended the abstraction of 22½ million gallons of water daily from the valley of the Lea, in addition to the 72 million gallons daily at that time obtained from that source. In September, 1894, circumstances remaining the same or nearly so, with the exception of the rainfall, the directors of the East London Waterworks, in consequence of the diminution in the water of the Lea, and in order to economise to the extent of 10 million gallons of water daily, are compelled to cut off the supply to their mains at night. No more practical testimony to the real value of the report of the Commissioners can be imagined. Not a word of comment is necessary."

Writing to the *Indian Engineer* a correspondent says, the chief difficulty to the success of the numerous punkah-pulling devices which are annually brought forward has been with the provision of motor power. "The punkah-wallah at four or five rupees a month is a cheap instrument, even if liable to get out of order, and hard to beat. The best attempts to supersede him have lain in the use of water-power in his place. For such work, as constant motion of almost invariable rate is required, very efficient impact motors are clearly indicated. A machine is therefore wanted which could claim to combine great efficiency with economy and steady working under comparatively low heads. It should be self-governing, self-lubricating, fairly noiseless, and readily started or stopped. On the whole, a simple and cheap appliance is the desideratum for turning water, at the comparatively low pressure at which it is generally supplied to houses, into punkah swings."

The telescoping of a large cupola, an accident which is said to be rare in the experience of foundrymen, is described in the *Engineering Record* as follows:—Possibly owing to faulty construction, the cupola spread at the charging door section, allowing the stack to drop about 5ft. The repairs necessitated some careful work, for it was desired to restore the cupola to its original position without removing the lining or taking it down section by section. This was expeditiously accomplished by first lashing the cupola at the top to the main building of the pipe foundry; then large cast iron shoes were bolted to the shell just above the roof of the cupola-house, and these in turn were bolted to long timbers 12in. by 12in., which were securely blocked and wedged into position as the cupola was straightened back into place by the use of chains and turnbuckles. As soon as in position, the under sections were taken away, leaving the stack in mid-air securely lashed to the building and supported by timbers and castings just described. The roof of the cupola-house was strengthened in the meantime by heavy timbers running from the ground to the cupola loft and thence underneath the roof. As the lower part of the old cupola was somewhat worn, and a new one of larger size was desired, a new 96in. Whiting cupola was erected in place of the old and joined to the stack, which had been held in place.

At a meeting of the Society of Engineers on Monday, a paper was read by Mr. T. W. Baker, B.A., on "The Utilisation of Town Refuse for Generating Steam." The refuse to which this paper refers is the usual contents of the ash-bin, with street sweepings and sludge, collected by local authorities. The recognised means of disposal is now by fire, so destroying all germs of disease, and the heat set free by the process of destruction, the author shows, by reasoning from his own experience and that of others corroborating him, should and can be utilised. The large bulk of 420 tons per week, collected from an average vestry area, necessitates a special furnace or destructor, while the noxious fumes arising have also to be destroyed. Up to the present time this has been imperfectly done, most of the heat having been allowed to go to waste. The author submitted a new system as efficiently meeting the difficulties, and the results deduced from his calculations and experiments showed that, after paying for the plant, working expenses, depreciation, interest, and redemption, a net saving of £2666 per annum could be obtained on a plant capable of dealing with 420 tons per week as above referred to. The author claims that this scheme is particularly applicable to the generation of electricity by the steam, providing a means for heat storage arrangements to meet the well-known fluctuation in demand; and for pumping, baths, and wash-houses, it is equally applicable.

# THE CONDITION OF THE THAMES BELOW KEW BRIDGE AT LOW WATER



## THE CONDITION OF THE THAMES—PROPOSED LOCK AND WEIR AT PUTNEY.

When poets of other centuries wrote of Thames that his "silver flood" was "strong without rage, without o'erflowing, full," they little thought that a time would come when, so far from overflowing, the stream would dwindle to the likeness of the attenuated rivulets of type that run through the broad margins of *editions de luxe*. But a water supply for several millions of people was undreamed of in those days, and no one ever imagined that one-third of the stream would pass through insatiate intakes at Thames Ditton, for the benefit of London water-consumers, leaving the Thames below that place a poor wraith of its former self, or, at all events, helping to bring about a condition of river bed which used only to occur after very dry seasons. We have prepared the above engraving to show what the river is now sometimes like. Another, and a newer grievance of the riverside parishes below Richmond, is the Richmond Lock and Weir, recently completed. It seems, according to the authorities of the several parishes of Isleworth, Brentford, Kew, Hammersmith, Mortlake, and Putney, that this new weir has rendered worse the already alarmingly inadequate flow of the river, and that navigation for steamers is becoming difficult. The remedy for this state of things is proposed in a scheme now being prepared for a new lock and weir to be situated at or just below Putney. A party, composed of engineering experts and delegates from the local bodies affected by the condition of the river, proceeded up-stream to Richmond some few days since in a launch of light draught, in order to observe the present state of affairs. One of the worst points appears to be at Kew, just below the bridge, off Strand-on-the-Green. Here the actual stream is reduced to a narrow gutter at low water, and steamboats that formerly experienced no difficulty in proceeding as far as Kew Bridge or Richmond, have become hopelessly grounded until the flow of the tide comes to their assistance. Kew Eyot can now be easily reached afoot, and even the deep and swift bend of the river opposite Brentford Creek, well known to boating men from the dangerous nature of the current at this point, is reduced to a shallowness that has never before been observed here.

Certainly a lock and weir at Putney would greatly improve the appearance of the river, and would do away with the offensive mud banks that now appear at every low tide; but this would be a big undertaking, of considerably greater magnitude than that below Richmond—itself the largest of its kind. The magnitude would not, however, of necessity be the stumbling-block. It has to be shown that the improvement would not be accompanied by an objectionable, or even harmful, condition of the river below a new weir; that it would not, in fact, merely hand down to the wharf-sided lower river below Putney the condition of things now existing above it, even with a year of plentiful rainfall. The extraction of water for the supply of the five millions of London people is possibly a sufficient explanation of most of the difference between now and half-a-century ago, but the difference imputed to the bridges and the embankment must not be overlooked. Moreover, it may be questioned, shortness of memory does not account for some of the alleged recent changes.

## HAMPSTEAD ELECTRIC LIGHTING STATION.

The new and commodious station for the supply of electric current to the parish of Hampstead was opened with great form and ceremony on Monday evening, October 1st, and it started its career without a hitch, in, we trust, happy augury of its future success, the light streaming forth without accident upon the action of Mr. Hackworth in throwing over a little switch deftly contrived upon the rail of the switchboard platform. The invitations had been issued for seven o'clock in the evening, and as, in order that the "switching on" of the light might be attended with true dramatic effect at eight o'clock, the guests were compelled to wander about in Cimmerian darkness for an hour, varying the monotony of such perambulations by now and then stopping to hear some speeches being delivered from the platform, and in which each excellent vestryman of St. John felicitated his brother, and all combined to compliment Mr. Preece, Mr. Alexander Siemens, and others of the contractors and engineers. When at last we got the "100 volts which is light," the crowd in the little station was so great that it was not easy to see much of the detailed arrangement, nor to get round many of the machines, but we hope at a later date to be able to study the many excellent points of the system adopted, and to give description and illustrations in detail, being content now with a general statement of the broad outlines.

The buildings consist of an engine-room in two spans, one of 26ft. and the other of 16ft. The size of the room is 58ft. by 42ft. by 23ft. high, and it is large enough to accommodate a 50 per cent. increase in the incandescent and arc lighting machinery. The boiler house is covered by one roof having a span of 43ft. It is 58ft. long and 24ft. 6in. high. Its floor is 9ft. below that of the engine-room, which is on the ground level, thus allowing space for coal bunkers under the roadway; these bunkers will contain 100 tons of coal. Complete and separate lavatory accommodation is provided for the engine-room and boiler house staff. The chimney is 130ft. high and 8ft. internal diameter; up to a height of 52ft. it is divided into two compartments, only one of which is used by the present boiler plant, the other half being provided for extensions. The offices are complete, consisting of the engineer's office, clerks' office, stores, and testing room. Separate lavatory accommodation is also provided.

There are four boilers of the Lancashire type, each boiler is 28ft. long by 8ft. diameter, and is guaranteed to evaporate 5000 lb. of water an hour, at a pressure of 150 lb. per square inch. The material used throughout is Siemens-Martin steel, and each boiler has been tested to a pressure of 250 lb. per square inch. The usual fittings are provided, and include two safety valves, duplicate feed-water check valves, and mechanical stokers. Coal is supplied to the stokers by a coal elevator, consisting of an endless chain and buckets working in a sheet steel case, and a conveyor, consisting of a worm working in a trough, from which the coal falls through shoots, placed at necessary intervals, into the stoker hoppers. The stoking machinery is worked by a small vertical engine, provided in duplicate, and the whole is arranged with clutches, loose pulleys, and striking gear, so as to be completely under control, and so that the breakdown of an portion of the machinery cannot interfere with the workin of the station.

There is a complete duplicate service of feed-water to each boiler, a supply being obtained from the water company's mains, and also from a storage tank having a capacity of 10,000 gallons. There are two Worthington feed pumps, each of which can supply water to any or all of the boilers, independently of the other. The feed-water is heated by an exhaust steam heater, and also by a Green's economiser of 192 pipes placed in the main flue. Each heater is provided with a bye-pass, and each can be used together with or independently of the other.

Steam is taken from the boilers to the engines in a wrought iron ring main divided by valves placed between each engine and each boiler into sections, each section being drained. A small auxiliary steam ring connected to two sections of the main steam ring supplies steam to the feed-water pumps and stoker engines. The exhaust steam is carried to the atmosphere 50ft. above the ground level, through a cast iron exhaust pipe. The engine-room contains the following dynamos, erected on solid concrete foundations, finished off with a plinth of glazed brick:—For incandescent lighting, one 200 kilowatt alternator supplying 5700 8-candle power lamps; two 100 kilowatt alternators, each supplying 2850 8-candle power lamps; one 20 kilowatt alternator supplying 570 8-candle power lamps. For arc lighting, two 13 kilowatt dynamos, supplying twenty-two 2000-candle power arcs. For exciting the above and for station lighting, two 18 kilowatt dynamos. The engines are by Willans and Robinson, and the dynamos of the Siemens type, and are in all cases direct coupled. The current is taken from these dynamos to the station switchboard, which is built up of polished slate panels, one panel being provided for each dynamo, and one for each circuit; through these panels the alternators are connected by omnibus bars to the circuits, and are arranged to work in parallel, a synchronising panel being provided for the purpose. Each panel is provided with the necessary instruments for measuring the current and electro-motive power, and the whole of the switchboard is mounted in a polished teak frame and is railed off from the engine-room.

The incandescent lighting current at a pressure of 2000 volts is taken from the main switchboard by high-tension feeder cables to seven sub-stations, each of which supplies a small area, all seven sub-stations being connected by low-pressure distributing mains. The feeders are Siemens H.C.N. type, protected with iron armour insulated with special fibrous material cased in lead, and are connected in the sub-stations to Siemens transformers, which transform from 2000 to 105 volts, at which pressure customers are supplied with current from low-tension mains, similar to the high-tension mains, but not so highly insulated.

The sub-stations are small brick chambers, 6ft. by 5ft., and are built under the pavement, access being obtained through a small manhole in the top. Each sub-station contains two 25-kilowatt transformers, a high-tension fuse board, and a low-tension switchboard, from which the distributing mains are taken, and so arranged that the supply to any length of dis-

# DYNAMOMETRIC CAR, WESTERN OF FRANCE RAILWAY

*For description see page 301*

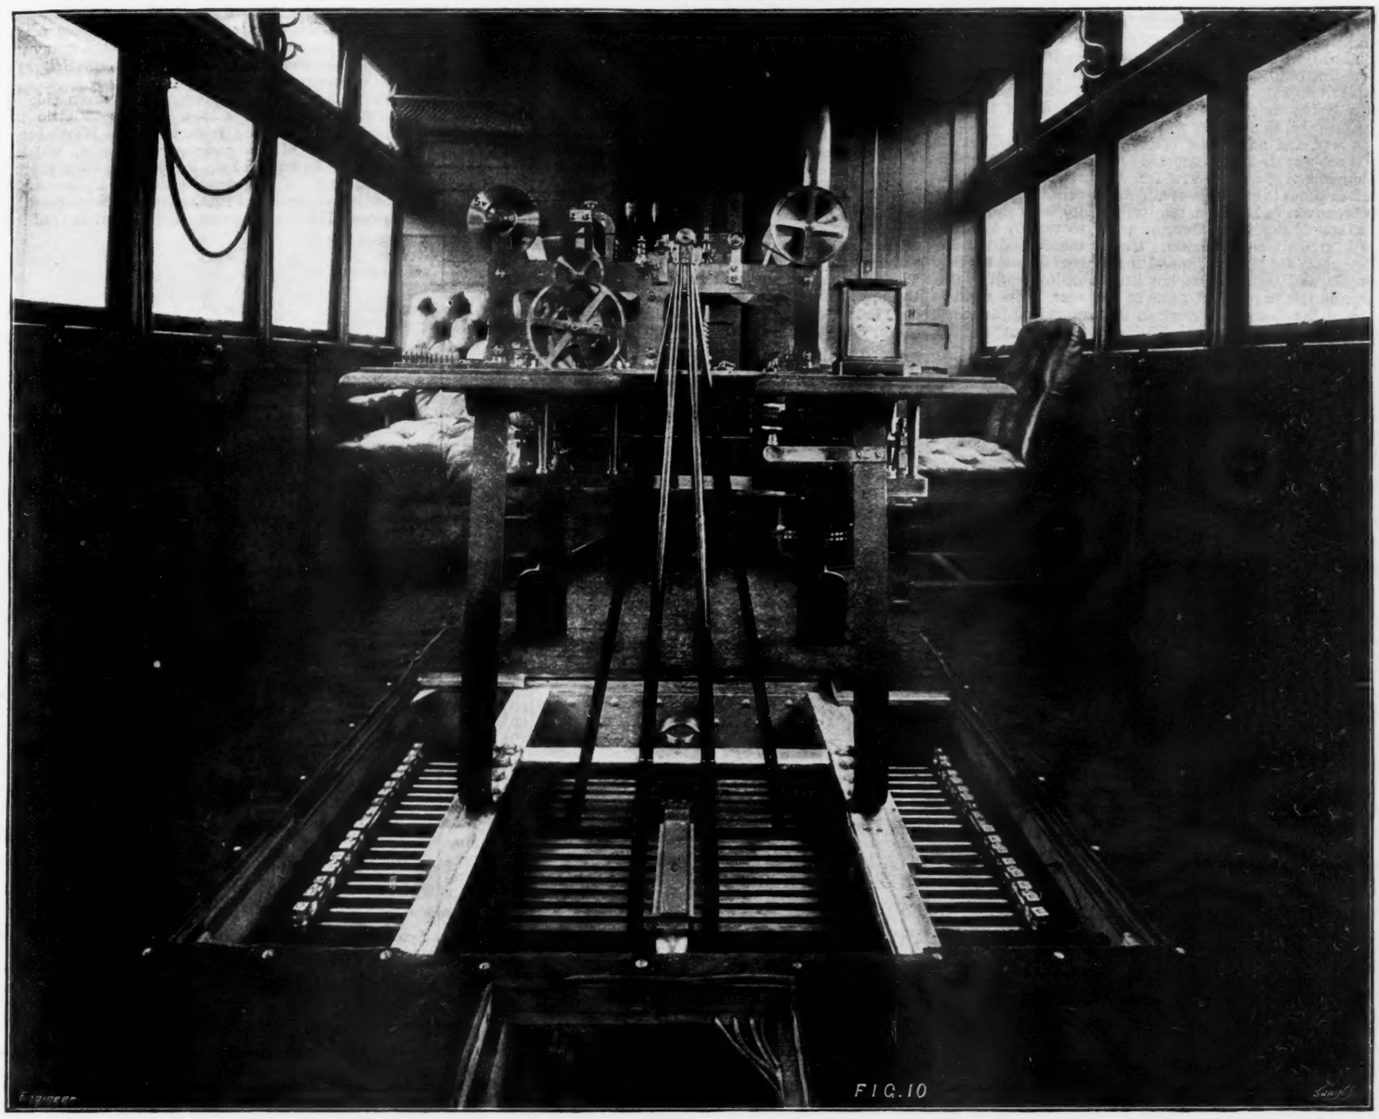


FIG. 10

tributing main between the sub-stations can be cut off for the purpose of connecting customers, without interfering with any other part of the system. Each sub-station will supply 1430 8-candle power lamps. The total length of feeder main is a little more than 3½ miles, and will carry current for the supply of 17,000 8-candle power lamps; the total length of low-tension main is 3½ miles, and is sufficient to supply 10,000 8-candle power lamps.

For street lighting twenty-two Siemens 2000-candle power arc lamps have been erected on iron posts in the Finchley-road. Each lamp post consists of a substantial cast iron base surmounted by a wrought iron stem and an arched bracket. They are supplied with current through a Siemens cable protected with iron armour and insulated with vulcanised rubber.

The building contractors are Messrs. Yerbury and Sons. The general plant contractors are Messrs. Siemens Brothers, Messrs. Willans and Robinson supplying the engines, Messrs. Belliss and Co. supplying the boilers and pipes, and Messrs. Lucas and Aird supplying the sub-stations. Mr. Arthur Ardron, F.R.I.B.A., acted as architect to the vestry. The whole of the scheme has been designed and carried out under the supervision of Mr. W. H. Preece, C.B., F.R.S., who has acted as consulting engineer to the vestry.

## THE WORKS AT THE PANAMA CANAL.

The company which has just been formed for taking over the works at the Isthmus of Panama has issued a report, giving what it professes to be an accurate idea of the present state of the canal. It had been expected that after being abandoned for nearly five years to the ravaging influences of the floods from the river Chagres, and the growth of vegetation which flourishes with remarkable luxuriance at the Isthmus, the works would have been greatly deteriorated, necessitating perhaps the re-excavating and banking of those sections of the canal already completed. Judging from the report issued by the liquidator, the canal itself has remained practically intact, and the machinery and other plant has only partly deteriorated from the climate. The first section of the canal, from Colon to a distance of 21·700 kiloms. has been greatly modified by the action of the river which has flown into it, and after following the incline of the canal for about 5 kiloms., the river deposits a great deal of sediment and turns off into the Rio Mindi, which has considerably enlarged during the past four years. Beyond the point where the Chagres breaks into the canal the works are in very good condition, though they are so covered with vegetation as to be sometimes indistinguishable from the surrounding country, and it is explained that this is one of the reasons why untechnical observers have insisted so often upon the complete ruin of the works. The report urges that, so far from being a disadvantage, this growth has actually been of service in preserving the canal, and the vegetation can be cleared away at very little cost. After the maritime reach, which terminates at 22·500 kiloms., are the works of the first lock, and these are in excellent state of preservation. From this point the cutting continues with an embankment 50 metres in height, but notwithstanding the steepness of the sides not a stone has given way, and this is set down to the protection afforded by the dense vegetation. This state of things is unchanged across the plain of Tavernilla as far as kilom. 36; at this point the excavation runs close to the river, from which the water descends during the rainy season. This is particularly noticeable between kiloms. 25 and 28 and between kiloms. 33 and 34. In the middle of the plain of Tavernilla are the large cunettes which, notwithstanding their steep incline, have been in no way affected by the severe floods of four years ago. The works facing San Pablo are also unchanged, though entirely covered with vegetation. The same condition prevails up as far as the second lock, where the cutting had first been made in view of a level canal, and then altered to meet the exigencies of the plan ultimately adopted. The canal then follows the bottom of the narrow valley, where it now and then cuts the river as far as the 40th kilom. The result is that the filling-up process has been very active, in consequence of the floods, and the vegetation in this part is particularly luxuriant. At Matachin, where preparations were made for the third lock, the works are often covered with water, but the cutting is nevertheless in a good state of preservation. After Matachin the canal leaves the valley of the Chagres and enters the valley of the Obispo. Here, at the 46th kilom., the works for the fourth lock are in good order, and owing to the eneven state of the ground the canal has a depth in certain places of 44 metres. A little more than a kilometre further on the banking fell in during the work of cutting. From the 48th kilom. a cunette has been made over a distance of several hundred metres through a very hard rock. Then, after passing the works between the Obispo and the Rio Camacho, the valley extends and merges into the plain of Emperador. In cutting through the high ground in this plain the canal has a depth varying from 35 to 40 metres. The fifth lock at this point is likewise in an excellent state. From kilom. 52·600 are the works of the Culebra, and at one place, where the depth is about 40 metres, the bank has fallen in. Notwithstanding the influx of water, the works are very much in the same state as they were five years ago, though between kiloms. 54·300 and 55·400 the soft soil that had to be cut through has given way. This is due entirely to the action of the water, and it is stated that with proper drainage the difficulty can be overcome. The same influence has been at work on the Pacific slope, where a great deal of shifting soil has been met with. Between the sixth and the tenth lock, descending towards the Pacific, there is nothing worthy of remark, except that the works are very humid and the vegetation is consequently very thick. From the tenth lock the valley opens out in a low, marshy country, and between kiloms. 65·500 and 66·700 the canal has been partly filled up. Further on the canal is in a better state of preservation owing to the water having a freer course. The maritime channel commences at the 68th kilom. It makes a detour around the mouth of the Rio Grande, and then continues in a straight line until within 200 metres of the northern point of Perico Island. In some parts, where the channel is exposed to the winds, it has been filled up by as much as four metres.

As regards the machinery and other material, the report speaks favourably but sparingly. Of the sixteen dredgers of 120-horse power ten are almost as good as new, and have hardly been used, but the others will require a great deal of repairing. There are several other dredgers, including two marine dredgers and two of the Suez type. All the floating material is found on different points of the canal, principally at Colon and upon the Pacific slope. The rolling stock is likewise distributed over different portions of the canal, and it is not in such a bad condition as might have been expected. Some of the locomotives have been repaired since 1888, and may again be put into service; but many of the wagons have rotted in the destructive climate. In short, it is thought that all the metal plant will be available for use after being overhauled. The wharves at Colon and Boca, the docks and other installations will have to be entirely reconstructed, and repairs will be needed in every direction before the work can be resumed. The railways will likewise have to be relaid; the wooden sleepers are entirely useless, but the steel sleepers are still serviceable. The rails, nuts, and bolts will all have to be replaced. In view of the many costly repairs that will have to be carried out before the work of cutting the canal can be proceeded with, it is difficult to fully understand the project of the new company, whose available capital of not more than twelve millions sterling will be practically swallowed up in preliminary works. It is not pretended, even, that the new company has any definite plan in view. The first object is to get a few hands at work upon the Isthmus, so as to fulfil the clause of the agreement with the Government of Colombia, which makes it necessary that the work should be resumed before the end of October, in default of which all the material would be confiscated. When half of the capital has been spent in preliminary works the technical commission will meet to decide whether it is worth while to continue the work, in which event the public will be asked to subscribe about twenty millions sterling. If, on the other hand, it is found inadvisable to pursue the undertaking any further, the money already subscribed will be used for working the Panama Railroad, in which the old company had a considerable interest. So far, no plan for completing the canal has been definitely adopted, and this matter will be left to the technical commission which will be appointed as soon as the company is in working order.

## ABSTRACTS OF CONSULAR AND DIPLOMATIC REPORTS.

*Germany: Coal and iron in Mannheim.*—As a coal market Mannheim is growing in importance; the arrivals by river in 1893 amounted to 1,171,678 tons. The year began with fair prospects for the coal trade, the severity of the winter having pretty well cleared stocks, and prices at the pit's mouth being low. In March consumption had again so far diminished that dealers were forced to accumulate stocks, and on the other hand the syndicate of coalowners was defective in organisation. Contracts had been based on the very low Rhine freights of 1892, which turned out to be a serious mistake, as not only was the river very low throughout the year, and navigation difficult and expensive, but all cargo space was strongly competed for owing to the unusually large shipments of corn and fodder. At the Ruhr mines it was difficult at times to get ships at all. And, again, when the coal strike broke out in England, the Ruhr mines were also called upon to supply the North German ports, so that it became, in turn, difficult to get coals. Under these conditions a regular supply for Mannheim and the Upper Rhine became impossible, and dealers were but little able to profit by the consequent rise in prices of some 25 per cent. The extending use of the so-called American stoves involved increased consumption of anthracite. The coal strike cut off the supply from England, and Belgium availed herself of the opportunity to secure a share for this kind of fuel in the fresh field of South Germany. All hopes entertained during the last few years of an improvement in the iron industry have hitherto proved deceptive, and if there was little good to report concerning consumption and prices in 1892, there is still less to be said for 1893. One large firm states:—"It would really seem as though we were getting towards the middle of the seven lean years, for there is hardly a trace of courage or enterprise left, and the condition of other branches of industry and trade is not cheering." This is taking too dismal a view of the situation, but in face of excessive competition, falling prices, finely cut profits and over production, the position of the German iron industry in 1893 was rather difficult. The tariff war with Russia had very disastrous consequences, the home market being flooded, but the manufacturers of agricultural implements and machines did a good trade. There was a strong demand for all kinds of machines for preparing cattle food. Agricultural steam engines and threshing machines were less in demand, but this was compensated for by the active inquiry of the corn and saw mills, that through diminished water had to resort to steam power. In almost all the branches of this industry represented in the Grand Duchy of Baden, such as boilers, brewing plant, chain, nail, and wire making, cranes, gas and boiler meters, hydraulic disintegrators and presses, pumps, railway axles, plant and springs, Roots' blowers, weighing machines, the trade was more or less unsatisfactory. Irish stoves have been introduced successfully into Baden for several years past, and in 1893 improved make and reduction of price caused a further extension of sales. The renewal of commercial relations with Russia will be of great relief to the German iron and metal industry, although it is not expected that the lost ground will be easily or quickly regained. As regards the iron industry in general, a comparison of prices during the last seven years may be of some interest, In all other descriptions prices were in proportion.

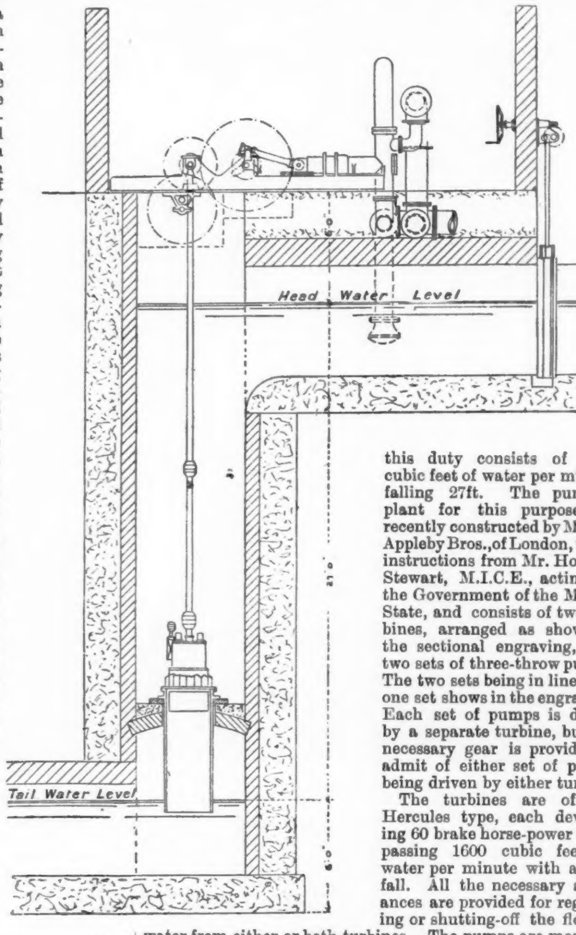
*Wurtemberg: Reports of factory inspectors.*—In general the year 1893 was very similar in industrial depression to 1892, but a slight improvement was noticeable. The building trades were active, especially those dealing with large towns, and brick kilns, cement and plaster works, also quarries were fully occupied. Saw mills and factories for building purposes did well; but those dealing with the agrarian population were less prosperous. Manufacturers of hardware and lamps report a satisfactory year, but there was a falling-off in refined steel, and some small works had to close, whilst others had to reduce their staffs and working hours. Iron smelting, tin trades, and machinery factories also report a good business, but there was a falling-off in orders for agricultural machinery. Wages are paid fortnightly when not weekly, and occasionally monthly, varying according to districts. Higher wages are paid at Stuttgart, Cannstatt, and Esslingen than at Heilbronn, Oehringen, and Hall. The system of workmen's committees produced satisfactory results in the cases both of employers and employed. The total number of accidents during the year was 1465, an increase over those of 1892; but the number of deaths and serious accidents were fewer. The increase was caused chiefly by the exceeding dry and warm state of the weather, which produced an amalgamation of dust. Attention is called to the habitual carelessness of the workpeople in spite of the various notices posted up warning them of the places where there is danger; but there is room for improvement in the better security of galleries, side entrances, and staircases, and provision of ventilation. The factory regulations are considered too detailed, and should be curtailed and made clear.

*Agricultural machinery in Southern Russia.**—According to the British Consul-General at Odessa, the scarcity of labour during last harvest caused a brisk demand for agricultural implements and machinery, especially steam and horse threshing machines. Every threshing machine that could be purchased here was sold off last autumn, and orders came in that could not be met. The demand this spring both for steam and horse threshers is very good, and all the orders received cannot be complied with. A very useful threshing machine worked by from eight to twelve horses is manufactured by an English firm at Elizabethgrad, in the province of Kherson, which seems to have met a want, and many thousands of these are being sold in that district. Similar threshing machines are also manufactured in Odessa.

## PUMPING MACHINERY FOR THE WATER SUPPLY OF THE CITY OF MYSORE.

The machinery which is illustrated by the accompanying engraving has been designed to supplement the existing water supply of Mysore, under the following conditions:—The additional quantity of water required for the service of the city, including provision for loss, is 1,300,000 gals. per day, to be raised to a height of 240ft. through a 14in. rising main, 8400ft. in length. The motive power available for this duty consists of 4200 cubic feet of water per minute, falling 27ft. The pumping plant for this purpose was recently constructed by Messrs. Appleby Bros., of London, under instructions from Mr. Houston Stewart, M.I.C.E., acting for the Government of the Mysore State, and consists of two turbines, arranged as shown in the sectional engraving, with two sets of three-throw pumps. The two sets being in line, only one set shows in the engraving. Each set of pumps is driven by a separate turbine, but the necessary gear is provided to admit of either set of pumps being driven by either turbine.



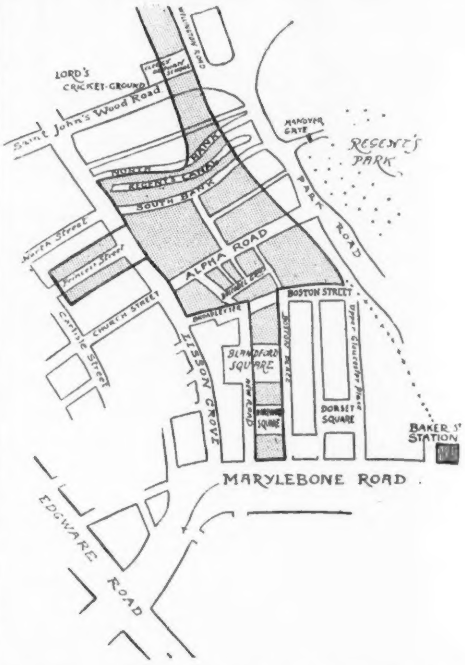
The turbines are of the Hercules type, each developing 60 brake horse-power when passing 1600 cubic feet of water per minute with a 27ft. fall. All the necessary appliances are provided for regulating or shutting-off the flow of water from either or both turbines. The pumps are mounted on strongly-ribbed cast iron girders, of the box section, bedded on concrete. The plungers are of gun-metal, 11½in. diameter and 18in. stroke. The turbine speed under the above conditions is 300 revolutions per minute, and the speed of the pumps twenty-five strokes per minute. Each set of pumps will deliver 450 gallons of water per minute against a head of 260ft., and they were tested to double that pressure. The suction and delivery valves are of hard gun-metal, and doors are provided for easy access to the valves. An air vessel is fixed over each valve chest. The shafting throughout is of mild steel, with bearings of gun-metal. Power is transmitted from the turbine spindle to the second motion shaft by means of bevel gear—the pinions being of malleable cast iron—gearing into mortice wheels with beech cogs. The arrangement is very compact and well considered. The floor space occupied in pump-house is 20ft. by 17ft. 6in.

## THE NEW RAILWAY TO LONDON.

The Bills having safely passed the House of Commons and the Committees, and the plans being now all complete, the Manchester, Sheffield, and Lincolnshire Railway Company is proceeding to work on the various sections of their new extension to London. The contracts have all been let, and the work of clearing the large area scheduled for the London terminus in St. John's Wood will be put in hand immediately. This particular portion of the new enterprise will be one of the most extensive London clearances of recent years, no less than sixty acres being set apart for passenger station, goods yards, and approaches in Marylebone. The shape and size of this area can be judged from the accompanying sketch map, and from a glance at it one may see how important an alteration this will make in this hitherto secluded and quiet artistic neighbourhood.

Coming from Finchley-road and Marlborough-hill, the new railway will run, chiefly in tunnel, beside the Wellington-road, and so underneath a corner of Lord's Cricket Ground and the Clergy Orphan Schools, across the Regent's Canal. Here the width of 124ft., which the new line will occupy from Finchley-road downwards, will spread out over an extensive tract bounded on the west by Grove-road, on the north by North Bank, on the south by Broadley-terrace and Boston-street, and to the eastward approximately by the Park-road. An offshoot will spring from the west side, running up to Carlisle street. Here will be situated a coal-station which, it is anticipated, will absorb a great deal of the London coal traffic which now-a-days centres so largely at King's-cross. The company looks forward with much satisfaction to the future of these new coal sidings; a satisfaction, it is scarcely necessary to say, not at all shared by the inhabitants of this shortly to be metamorphosed neighbourhood. To anyone who is acquainted with the grimy purlieus of King's-cross and Battle-bridge, the alarm felt by these folk will not seem uncalled for.

Another offshoot springs from the southern side of this large area, and runs in a long and narrow strip through Blandford and Harewood squares to the Marylebone-road. This is the site of the passenger terminus, which it is intended shall be fronted by a large hotel, after the manner of Euston and St. Pancras Stations. Alpha-road, South Bank, Boscobel-gardens, Princess-street, Omega-place, Blandford-square, Harewood-square, and a number of smaller thoroughfares will be demolished; and a new road of the commendable breadth of 60ft. will be formed from the Park-road to Lisson-grove, through Boston-street and Broadley-terrace. Another new road will be formed on the next side of the passenger station, running from the Marylebone-road and joining the other new thoroughfare at the point where the goods-yards will commence.



Baker-street Station will, as hitherto, be used for purely local traffic, and the Metropolitan line from Finchley-road to London will be quite distinct from the new scheme. Lord's Cricket Ground will derive an immediate benefit from a portion of land formerly belonging to the Clergy Orphan Schools being handed over to the club, as the price of the withdrawal of their opposition to the scheme; but it seems likely that this concession will be made altogether valueless by the radical change in the character of the district that is bound to follow the setting up of a great terminus in the midst of a high-class residential neighbourhood; and with this change will essentially come the removal of Lord's to a purer atmosphere, and some quieter corner than this will be in time to come. Already, artists whose number has given this quarter so distinctive a *cachet* have taken alarm, and, even where their houses have not been scheduled for appropriation by the railway company, are removing to "fresh fields and pastures new," prophetically conscious as they are that the quiet roads of villas, isolated within high garden walls, that are so characteristic a feature of St. John's Wood, will inevitably give place to streets of shops and the busy haunts of commerce that invariably accompany the termini of great railways. Some time since the occupants of the houses required for the new railway were served with notices requiring them to give up possession; but one artist, wishing to remain to the last, on asking what would be done with his house after he had gone, being told that a caretaker would be installed, suggested that surely he himself would be the best caretaker possible. His offer was accepted, and there he is to-day.

## SPRATT'S ELECTRICAL SPEED AND DIRECTION INDICATOR.

While great advances are being made in our ships, both for the Royal Navy and for our mercantile marine, and while the brain power of our marine engineers might almost be said to exhaust itself in perfecting the design of steam machinery for vessels great and small, there is another field of progress which has not been allowed to go to waste; and much of the success in handling such a complex mass as one of our great battleships must depend upon the skill and genius of the instrument maker who provides the means for intercommunication, for control, and for observation which are necessary to the efficient and trustworthy working of every department on board ship. The old-fashioned skilled handicraftsman who made instruments a generation ago has given place to the modern scientist, who devotes the highest powers of a trained mind, and the most perfect mechanical knowledge and workmanship to the production of instruments of great delicacy and accuracy, without which modern progress could not have been what it is.

In a recent number of The Engineer we described some cleverly designed instruments which have been fitted by Messrs. Elliott Brothers on board ships of all sizes and for all services, and we have since then had the opportunity of closely examining the working at sea of a new electrical speed indicator which is being introduced by the same firm, and which we now illustrate.

Amongst the various systems of signals required on board ship, perhaps one of the most important is a ready means of quickly ascertaining on the bridge or in the chart house—or in a warship, in the conning tower—the number of revolutions per minute of the engine shaft, or shafts in the case of a ship fitted with twin screws. This need is now felt more than ever, on account of the present tendency to fit ships with higher speed engines. Consequently many inventors have been at work on the subject, and a great number of attempts has been made to produce a trustworthy instrument for filling this requirement. Mechanical contrivances have been designed, but these have presented difficulties in large ships, especially as it has been found very inconvenient, and in some cases impossible, to take the necessary gearing from the shaft to the bridge, the friction of the working parts at this distance being too great to allow of the indicators being worked with satisfactory results.

SPRATT'S SPEED INDICATOR—CONNECTIONS

Pneumatic and hydraulic contrivances have from time to time been experimented with, but have developed defects which have been fatal to their introduction. The inventor of the instrument under notice has adopted electricity as the base of his system, but has applied it in a different manner to any that has before been attempted, and by so doing has devised an apparatus which is not only practical, but gives the result with the greatest accuracy. This has been verified by a severe trial, extending over a period of six weeks, made on a torpedo boat, the instruments being subjected to the excessive vibration of the boat going at full speed, and exposure to rain and sea water; in fact, the indicator at times was completely under water.

The engineer stated at the termination of the trial that in no case, even at the highest speed of 400 revolutions per minute, had there been a variation of 2 per cent. between the readings taken on Spratt's speed indicator and those taken on the engine counter working directly off the shaft, and this error, being always in the same direction, could easily be allowed for.

The general arrangement and working of the revolution counter is as follows: — Looking at the diagrammatical sketch Fig. 1, the contact maker is shown on the left. It consists of a metal ring A fixed round the shaft, the number of revolutions of which it is desired to record. There are four pieces of insulating material let into the periphery of the ring, which, passing under the metallic brush R, break the circuit four times for every revolution of the shaft. There is a second brush *f* which is continuously in contact with the metal part of the ring. The control box contains a simple self-winding electrical clock, which makes and controls the duration of the necessary contacts. The counter or indicator is shown on the right-hand side of sketch; it contains the counting mechanism, and the indicator for showing whether the shaft is running ahead or astern; there is also the necessary mechanism for automatically putting the counter to zero before the counting mechanism commences its operation. When it is desired to know the revolutions at which the shaft is running, the button $P^1$ on the right-hand side of the indicator is pressed in; this causes a current to flow from the battery along the wire marked B Y to the terminal of the indicator marked B Y; thence by a wire to the top contact of the button $P^1$, and to bottom contact, and by a wire to terminal 4; from there by the wire 4 to terminal 4 on control box; from there through the large magnet B, which winds up the clock by pulling on the left-hand end of the arm C, thus extending the spring $D^1$ which is the driving spring of the clock. Directly this is done, the spring catch H jumps over the projection I on the wheel F, and breaks the circuit through B. At the same instant a current is sent through the small magnet *a*, by the right-hand end of the lever C coming against the contact *b*; the magnet *a* now attracts its armature *c*, and pulling the lever *d*, gives the escapement wheel E a flick and starts the clock; the above cycle of operations is almost instantaneous. The clock being started the cam wheel G revolves, the pin J presses down one end of the lever $J^1$ and closes the contact at the other end of it. The current now flows from the battery again along the wire B Y through the magnet M, which operates the zeroising mechanism and sets the counter to zero. The pin J having passed over the end of the lever $J^1$, the circuit is broken. The cam-wheel G next lifts the end of the lever $J^{11}$ and closes the contact O at the other end; this is the counting circuit and is kept closed exactly fifteen seconds. This period, however, may be shortened if desired by increasing the number of contacts on the shaft ring). The current now flows through B Y, again through the magnet P, then through the magnet $Q^1$ down the wire marked I to the terminal *l* of contact-maker; thence to the contact S on to the cross piece of the brush R, then where the metal part of the ring comes under, across to the brush *f*, and thence by wire 5 back to control box and to battery. The counting circuit being closed for fifteen seconds, and this circuit being broken by the ring four times for every revolution, the number of revolutions per minute are thus recorded. The brush R in the contact-maker is pivoted at $f^1$ and is thus carried over by the friction of the brush rubbing on the ring, and the contact S or $S^1$ is closed according to which direction the shaft is running; the current thus flows either through the magnet Q or $Q^1$ in the indicator, and by means of an armature pivoted between them turns a disc showing either ahead or astern, as the case may be.

The operation of taking a record is, therefore, briefly as follows:—On pressing the button at the side of the indicator, Fig. 2, the last indication is automatically cleared away and the wheels set to zero. So soon as this operation is completed the counting commences and lasts for fifteen seconds, at the end of which time figures appear at the circular openings of the indicator showing the number of revolutions per minute, and at the large opening is indicated the direction. For instance, if the figures 1, 2, 5 (ahead) appeared at the openings it would indicate the engines are working 125 revolutions ahead. Whilst these operations are going on, all instruments in the circuit are automatically locked, so that it is impossible for anyone, by pressing the button of any other indicator, to upset the record being taken. The following are the advantages claimed over other systems:—(1) Great and uniform accuracy at high and low speeds. (2) A number of indicators can be worked from one control box. (3) If any indicator be damaged in any way, it does not affect the working of the others. (4) The indicators are not affected by the rolling, pitching, or vibration of the ship. (5) All vital parts are enclosed in a water-tight case. (6) The speed is given in figures, and not by a hand pointing to divisions, thereby avoiding any mistake in reading. (7) No winding of clocks required. The only attention required to keep the system in good working order is the occasional lubrication of the contact ring on shaft.

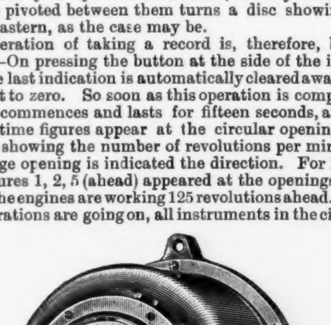

Fig. 2—SPEED INDICATOR

## ROADS AND RAILWAYS OF ASIA MINOR.

According to the British Consul at Aleppo a public road from that place to Biredjik, on the Euphrates, a distance of eighty-five miles, has been commenced, and 12½ miles of it completed. Permission has been granted by the Government to convert the existing camel road from Aleppo to Afseen into a carriage road, by which twenty-four miles will be saved between Aleppo and Alexandretta.

The hopes raised that the recent grant of railway concessions in Asia Minor, Palestine, and Syria by the Ottoman Government would include one of a short line from Aleppo to its natural port, Alexandretta, a distance of 100 miles by the carriage and seventy-five miles by the ordinary camel and mule road, have not been realised, and the consequent development of the province is retarded.

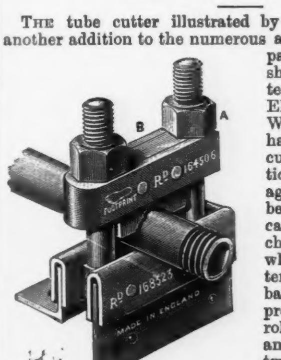
In June, 1893, a concession was granted by the Porte to Mr. Motran, acting on behalf of a group of French capitalists, for a line of normal gauge from Damascus to Biredjik, on the Euphrates, a distance of about 350 miles, with power of extension to Telek, near Diarbekir, a further distance of 150 miles. This group has since amalgamated with the French company constructing the port of Beyrout, the steam tramway from Beyrout to Damascus, a distance of about ninety-two miles, and the Belgian steam tramway from Damascus to the plains of the Hauran, forming together what is known as the Compagnie des Chemins de Fer Economique de Beyrouth-Damas-Hauran en Syrie.

The line from Damascus to Biredjik has a Government mileage guarantee of £804 13s., and would be 306 miles in length to its junction with the steam tramway between Beyrout and Damascus, the places passed through being Aleppo, Hamak, Homs, Baalbec. This gives the railway distance, with break of gauge, from Biredjik to Beyrout at 344 miles, and from Aleppo to Beyrout at 250 miles. The military authorities are said to view unfavourably this proposed deviation from the direct route of Aleppo to Damascus, with the disadvantage of break of gauge, and prefer the line being carried direct from Homs to Damascus, which would lengthen the railway distance from Aleppo to Beyrout by about forty-four miles, making from Aleppo to Beyrout 360 miles, and from Biredjik 440 miles. As to the proposed railway rates, the Cahier de Charges fixes the minimum charge at 2·355d. per ton per mile, thus making the lowest cost of transport of a ton of merchandise from Biredjik to Beyrout by the company's proposed route to be £3 6s., and from Aleppo to Beyrout £2 8s., while by the direct route *viâ* Damascus, insisted upon by the military authorities, it will be £4 5s. and £3 6s. 9d. respectively. This is irrespective of extra charges, such as carriage from the warehouse at Biredjik or Aleppo to the railway stations, carriage at Beyrout to the quay, and the new port and quay dues, which are very heavy.

Against these prospective charges for produce by railway transit must be placed the far cheaper and economical charges by camel and mule direct to Alexandretta, averaging from Beridjik £2 6s., and from Aleppo £1 10s. per ton. These rates are subject to violent fluctuations, and in March last heavy produce was being carried by camel from Aleppo to Alexandretta—75 miles—where there are not any port or quay dues, at 15s. per ton. The same considerations apply to the produce of Mesopotamia brought for export through Biredjik, and to that of the plains of Hamak and Homs, of which latter Tripoli is the natural port. In all these cases the proposed line cannot compete with the camel, while the Government has to pay a serious annual charge for the mileage guarantee. It is calculated that all possible available traffic can at the minimum rate barely reach one-third of the guarantee, as producers will inevitably prefer the much cheaper, if not the most expeditious, route by camel and mule to Alexandretta. The company has by its concession the preference to construct branches to the sea, but these would be a serious detriment to the main line, and reduce its small earnings to nil. Such short lines—Biredjik to Aleppo, 94 miles; Aleppo to Alexandretta, 75 miles; Hamak to Homs, 31 miles; and Homs to Tripoli, 60½ miles—if working independently, would compete most successfully with the camel and do wonders for the country.

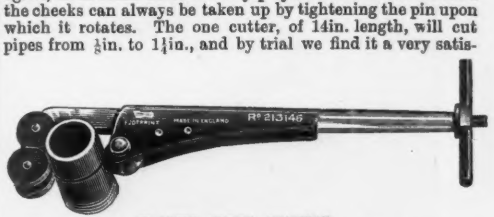
While produce, chiefly grain, the principal resource of the district, rots for want of cheap communication with the sea, it can hardly be expected that the hopes of the company to develope production and attract traffic by the simple process of doubling or trebling the cost of transport can be realised.

## A NEW TUBE CUTTER.



TUBE VICE

The tube cutter illustrated by the engraving below is another addition to the numerous articles made wholly or in part with pressed or stamped sheet cast steel, on the system adopted by Mr. T. R. Ellin, of the Footprint Works, Sheffield. The main handle bar of this tube cutter carries four anti-friction rollers at its outer end, against which the tube to be cut bears. The cutter is carried between two side cheeks, which, with a tube which slides over the internal part of the handle bar, are of a piece of pressed sheet steel. The roller cutter is held upon an adjustable steel pin between these, and it therefore takes a position central between the anti-friction rollers, which are on either side of the handle bar. The burr thrown up by the cutter thus runs between the anti-friction rollers, and is not continuously rubbed down and rolled up again, as in some cutters. Any play between the cutter and the cheeks can always be taken up by tightening the pin upon which it rotates. The one cutter, of 14in. length, will cut pipes from ⅛in. to 1¼in., and by trial we find it a very satisfactory tool. The cutter, it should be mentioned, is set up by the fly or bar nut seen at the end of the handle.



ELLIN'S TUBE CUTTER

Mr. Ellin is also making a "Footprint" pocket tube vice for the use of gasfitters. It is very similar to that illustrated by the accompanying engraving, but with a single steel angle piece for each side of the lower jaw instead of that shown. It will take tube from ⅛in. to ⅜in., which is as large as gasfitters usually require; and it is easily carried and temporarily fixed to a bench or table or plank.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

⁂ *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

⁂ *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

⁂ *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

J. L. (Leicester) —*The tank will hold* $10 \times 10 \times 12 = 1200$ *cubic feet.*

A. E. K.—*You will find it necessary to use a check spring acting against the weight.*

G. A. R. (Newport).—*Your letter is so vague that it possesses no interest whatever. If you discard steam, gas, and electricity, you have nothing left as motive power, for muscular effort will not suffice.*

J. G. (Sheffield).—(*1*) *There is no rule for calculating the strength of spiral springs which is worth much. Rankine gives* $D = \sqrt[3]{\frac{w \times d}{3}}$ *for round steel. Here D is the diameter of the wire in* $\frac{1}{16}$ *of an inch, w the weight in pounds, d the diameter of a coil centre to centre. We have not space here to do more than refer you to Clark's "Rules and Tables," page 672.* (2) *In calculating the area of such a figure as that enclosed, the best plan is to cut out a parallelogram of good cardboard which will just enclose the figure drawn on it with fine ink lines Weigh the cardboard accurately. Calculate its area. Then cut out the figure whose area you want and weigh it. Its area will be to that of the parallelogram as its weight is to that of the parallelogram.*

## SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)* .. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
*Half-yearly* .. .. £0 18s. 0d.
*Yearly* .. .. £1 16s. 0d.
Thick Paper Copies—
*Half-yearly* .. .. £1 0s. 3d.
*Yearly* .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

## ADVERTISEMENTS.

⁂ *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

## MEETINGS NEXT WEEK.

The Junior Engineering Society.—Saturday, October 6th, at 3.30 p.m. Visit the Gigantic Wheel Works, Earl's Court Exhibition, West Kensington.

## DEATH.

On Sunday, September 30th, at his residence, Havelock-road, Croydon, **William Topley**, of her Majesty's Geological Survey. Aged 53. Interment is at Woolwich Cemetery, 4.30, Thursday, 4th inst.

# THE ENGINEER.

*OCTOBER* 5, 1894.

### ARTILLERY FIRE IN THE CHINESE WAR.

The story of the battle of Yalu has now been told in various ways, and the accounts are, on the whole, consistent, so that we can draw some conclusions as to the behaviour of heavily armoured ships and cruisers, and as to the effects of the fire of guns of new type. That story we have told in another page. The opposing fleets were singularly different in their character. That of China consisted of four fairly modern barbette ships; two, the Chen Yuen and Ting Yuen, each of 7430 tons displacement, carried compound armour from 14in. to 12in. thick, with powerful 12in. Krupp guns and auxiliary armaments of 6in. guns and mitrailleuse, but no quick-fire guns. In fact, they were good representative heavy armour-clads of their dates, that is of 1881 and 1882. The King Yuen and Lai Yuen were much less powerful, each only 2850 tons, but were built in 1887, and the Ping Yuen is a coast defence ship of 1890. With these were the unarmoured cruisers Chih Yuen, Ching Yuen, Tsi Yuen, Yang Wai, and other ships of less importance. The main features, then, of the Chinese fleet were heavy guns and thick armour. Their defensive power was in some cases great, and they were capable of striking very heavy blows, but few and slow compared to those the Japanese ships could deliver. Two Chinese cruisers had a speed of 18 knots, but the barbette ships had at most a nominal speed of 16½ knots, and we think that their actual speed fell very far short of this. Of the Japanese fleet we have less particular information. It consisted, however, of armoured and unarmoured cruisers. Indeed, the Japanese only possess one ship carrying more than 4½in. of armour on a belt, namely, the Fu Soo, an old-fashioned central battery ship of 1877, carrying 9in. of armour, and she counts for but little. In any case the character of the Japanese fleet was wholly different from that of China. Some Japanese ships possessed high speed. The Yoshino is credited with 23 knots, and carries an armament entirely consisting of 6in., 4·7in., and smaller quick-firing guns. The Akitsuschima has a speed of 19 knots. The Naniwa and Takachiho are sisters, of 18·7, and the Itsukusima and Metsuchima of 17·5 knots speed. Many of the Japanese ships, however, could not have been faster than those of China. The Akagi, for example, is a 615 ton ship, of only 12 knots speed; nor could they have carried many powerful quick-fire guns. In short, if we consider the general bearing of the battle on the probable future of the war, it argues very badly for China, for it may be seen that her entire armour-clad force except one gunboat was engaged, and while the Japanese ships were decidedly faster than the Chinese, the powers of the former, both offensive and defensive, must in many cases have been inferior to that of their adversaries. The commanders appear to have handled their ships at least as well as could be expected. The Japanese captains tried to keep up a running fight at long ranges. Probably from being in better condition, practically the whole of the Japanese ships had the advantage in speed, and being better gunners and sailors, it was to their advantage to fight in this way.

The Chinese tried to close, and the evolutions are described as consisting of the circling of the Japanese divisions round the Chinese, the latter running in smaller circles. The Chinese unarmoured cruiser Chih Yuen, having a speed of 18 knots, tried to utilise her powers, and ran straight for a Japanese ship, which, the Chinese say, was sunk, though not, it seems, by ramming; indeed, the actual sinking is a little uncertain. Apparently the Japanese Yoshino, the most modern and formidable ship in their fleet, was very severely handled. Eventually the Chih Yuen was herself sunk as well as the King Yuen—armoured barbette ship—and a third Chinese vessel, the Choo Yung, as well as the fourth ship eventually, both the last apparently of less importance. The two heaviest Chinese armour-clads, the Ting Yuen and the Chen Yuen, appear to have got into thick of the Japanese fire, and to have borne the brunt of the attack admirably. Their upper unarmoured portions were naturally riddled, but the barbettes and vital parts were not penetrated. It could hardly be otherwise, seeing that the 6in. quick-fire guns are not nearly powerful to pierce them, and consequently the hundreds of shot that made holes or indentations 3in. deep were thrown away. The firing generally was at a long range, and was therefore necessarily not directed to the best purpose, so that much of it was wasted, and we do not doubt that the Japanese had run out of ammunition, and their retirement was a necessity. The Chinese, however, were also running short of shells, and were in some cases using steel shot to bad purpose on their unarmoured adversaries.

The first lesson to be drawn seems to us the very obvious one that, if a fight is to be carried out at long range, eventual success greatly depends on the supply of ammunition. Nearly all the injury done was effected by artillery fire, neither the ram nor the torpedo was used to any purpose, indeed, hardly tried, but the action taking place at long range, there was probably little scope for them. Even under these circumstances, the destruction was less than might have been expected. The Chinese appear to have shot very badly. It is, however, to be borne in mind that the fire in each case was that which the enemy could best resist. The Chinese armour was absolutely inpenetrable to the Japanese guns, so that their possible scope was limited to the destruction of the structural parts of secondary importance. On the other hand, the Japanese armour would have been perforated by quick-fire guns, and the entire ships would have been cut away at a great rate, had the Chinese posssesed quick-fire guns. Instead of this, they were only exposed to very slow fire. The actual projectiles employed against them were certainly very powerful and a fortunate shell might totally destroy a Japanese ship; but at a long range with bad gunners, this was not very likely to happen, so that the Japanese were exposed to a much less severe ordeal than if the enemy had consisted of cruisers of their own type. It must be remembered also that the Chinese ships were only exposed to a very limited number of heavy quick-fire guns, for most of the Japanese ship's armaments, while they consisted of excellent new type pieces, did not include heavier quick-fire guns than 6-pounders.

On the whole, then, we are forced to the conclusion that the general lessons to be drawn from this battle are influenced by the following facts:—First, that the long range precluded our learning much as to the use of the ram or torpedo, and secondly, that the artillery fire was in each case the kind which the fleet was best able to bear. We fear that in a close encounter, when these peculiar features were not found, the destruction would be very much greater. This would no doubt make it less likely that the fight would end, as we imagine it did in this instance, from the supply of ammunition failing.

The immediate effect on the war is, as we have said, likely to be very bad for the Chinese. Their whole armour-clad fleet having concentrated, the Japanese have not feared to attack it and give a very good account of it, sinking four ships, and demoralising the Chinese navy no doubt. We can fancy a parallel being drawn between their action and that of our fleet, when it fought the Spanish Armada. We prefer, however, to confine ourselves to more practical issues. Let us consider what would happen if really brand-new ships and armaments were to engage. Lord Armstrong on September 28th—last Friday—spoke of the extraordinary ballistic powers that have been developed with cordite. The velocity of 3000ft. has been attained with a 100 lb. shot from a long 6in. gun. A speed of six rounds a-minute has been achieved under service conditions when the ship was in motion, and firing with such accuracy as to hit a target twelve or even fourteen times out of eighteen. The significant features in this statement are, we think, the speed and accuracy under service conditions, coupled with the fact that there is no smoke. On the very high velocity we lay very little stress, because experience has shown that even for direct-fire, projectiles require to be very excellent to hold together on impact at very high velocities, and on service most of them would strike obliquely. The increased speed, accuracy, and absence of smoke, however, would tell so greatly that we think the battle would be brief and terrible, and that it is a question whether a fleet possessing sufficient speed to control the range, and a larger supply of ammunition, would not have the possibility of destroying an enemy by the tactics of long bowls carried out with such success by the Americans against ourselves in our old war. Happily, British ships at present, we believe, carry a larger supply of ammunition than those of other navies. Moreover, it is possible that if cruisers tried this experiment against heavy ships commanded by cool men with good gunners under them, they might find some of them were sent to the bottom by the occasional powerful shell that the heavy battleships would discharge. Lastly, we would call attention to the fact that the Ting Yuen and Chen Yuen have not complete armour belts, and that they were exposed to the main attack of the Japanese quick-fire, so that the conditions were those which would fairly try the powers of the horizontal armour, and it appears to have answered its purpose.

### THE WORKING OF THE RAILWAYS.

Board of Trade publications respecting the railways of the United Kingdom have lately been coming upon us in rapid succession, three of these documents appearing on as many consecutive working days. Two cover the whole of last year, and a third consists of returns relative to accidents occurring in the first half of the present year. All are in the form of papers presented to Parliament. The two which refer to 1893 are each described as a general report, one treating of accidents and the other of finances, including revenue and working expenses. This latter report is based on the returns issued by the Board of Trade in the month of August, and on which we commented at the time, giving many of the results and comparisons which now appear in the official report. The account now presented points out the serious extent to which the railway receipts were affected by the great coal dispute of last year. Until 1893 there had been no actual decrease in the gross receipts of the railway companies for seven years, and for the forty years over which the records extend the figures show an almost uninterrupted increase. The reduction last year, although it does not stand quite alone, is yet without precedent in regard to its amount, this being as much as £1,460,000. Following the usual tabulated statement as to traffic receipts, working expenses, and net earnings, the remark is made that "from whatever point of view this table is looked at, the general result is unsatisfactory." A sentence pregnant with meaning says, "The dislocation of trade and industry caused by the coal strike of last year will long be remembered by those interested in railway undertakings as materially helping to produce net results which make 1893 the worst year on record, so far as they are concerned." A hope is expressed that the ground lost in 1893 will prove to have been made good in 1894, and that the revenue side of the account will even show some improvement as compared with 1892. Unfortunately the coal strike in Scotland will not help to make matters better, though it has been partly counterbalanced by the quickened coal trade in the North of England. The effect on the iron and steel industry beyond the Tweed has been exceptionally hurtful, and the Scotch railways have suffered in their mineral and goods traffic.

If railway finances languished in 1893, there was a bright feature in the chapter of accidents. The passengers killed by accidents to trains were seventeen compared with twenty-one in the year before, and the proportion was simply one passenger killed in above fifty-one million passenger journeys. There was also a decrease in the number injured by accidents of this description, the reduction being considerable compared with the previous year, and falling as much as 45 per cent. below the number in 1891. It is true that the number killed in 1891 was only five, but twelve passengers lost their lives in one disaster last year, near Llantrissant Junction, on the Taff Vale Railway. If these were deducted, we should get the same result as in what is now the best year on record. We have remarked on a former occasion how one accident on a large scale will mar the statistics for the whole year. In 1879 only two passengers would have been killed had it not been for the terrible Tay Bridge disaster, which by a singular fatality happened only three days before the year came to a close. In the first half of the present year no passenger has been killed by a train accident, and only seventy-three have been injured. But the passengers killed last year were only one in the first six months, leaving sixteen to come later on.

There is one fact in the history of 1893 which is eminently satisfactory. The train accidents were fewer than in any year since 1874, and probably the favourable comparison might be carried further back, if the figures were produced. Forty-six train accidents in 1893 stand in striking contrast to 161 in 1875, when the traffic was so much less than it is now. In seventeen instances last year collisions occurred within fixed signals at stations or sidings; ten accidents were due to engines or vehicles meeting with obstructions, or leaving the rails in consequence of obstruction, or as a result of some defect in connection with the permanent way or works. The next in point of frequency were eight accidents arising from trains entering stations at too great speed. In these three classes there were thirty-five accidents out of the entire forty-six, whereas in 1881 the corresponding group registered sixty-five. Collisions within fixed signals at stations or sidings have fallen off one-half, and accidents from engines or vehicles leaving the rails have declined in a still greater degree, though not to the same extent as in 1890-91-92. While accidents from excessive speed in entering stations happened on eight occasions last year, there were ten such occurrences in 1892, and fifteen in 1891, but only two in 1890.

Among the accidents of 1893, one was somewhat singular in its operation, a down train on the South-Eastern line running through the gates at a level crossing near Erith, and one of the passengers subsequently dying from the shock. It transpired that the man in charge of the gates could neither read nor write. A copy of the rules relating to his duties was found in his box, but it did not appear that they had been explained to him. Of course the great disaster of the year was that which happened on the Taff Vale line. This was due to the fracture of a T-link hung from the axle-box of the engine, to which was attached an under-hung spring. The latter ultimately fell off, and got under the wheels of the leading van, causing it to leave the rails. Out of the seventeen collisions within fixed signals at stations or sidings, fifteen are attributed to mistakes or negligence on the part of the companies' servants. In three cases attention was called to long hours worked by the employés. Taking the whole range of the forty-six train accidents, it is found that as many as seventy-five circumstances contributed to their occurrence. Of these practically one-half are reported as due to "negligence, want of care, or mistakes of officers or servants." In seven instances we are told of defective arrangement of signals or points, or the want of proper locking apparatus. Excessive speed is mentioned in five cases. In all the preceding years the contributing circumstances were more numerous, being as many as 212 in 1883. Of the specified train accidents, four occurred on the North British line, and a like number on the North Eastern. These were the highest number on any line. But we are bid to remember that accidents taking place upon a railway may occur to trains belonging to other companies, and may not be caused by any fault of the company owning the line.

The accidents to servants of companies show a tendency to diminish. The number killed by train accidents last year was 10, and from other causes 450. There have been better years, so far as absolute numbers are concerned, yet there is a marked improvement compared with periods about 1874 and some time afterwards. The fatalities arising out of coupling and uncoupling operations are fewer than in previous years. Including all shunting operations, the killed were 125, whereas the fatalities in 1892 were 158, and in 1891 rather higher. Compared with the number employed, the loss of life is greatest amongst shunters, being at the rate of one in 179, the injured being one in 17. This is a melancholy record, and the report states that although there is a decrease in the casualties, both on the whole and in respect to shunting, yet "the figures must be looked upon as far from satisfactory." It is further intimated that the subject is receiving the earnest attention of the Board of Trade. While the employés thus suffer, it has to be observed that a large number of accidents befall the passengers from a variety of causes, in some of which their own want of caution or their actual misconduct are concerned. Eighty-nine lives were lost in this way last year. But in 1892 there were as many as 108. Apart from the passengers, trespassers present an extraordinary total, and show an increase of fatality, 274 being killed last year, compared with 258 the year before. Deaths at level crossings undergo a reduction from 77 to 55. Suicides are slightly fewer, being 86 in place of 89, and the miscellaneous class are 30 instead of 43. The total death roll for 1893 is 1011, and it is somewhat encouraging to find that this is 119 less than the total for 1892. The cases of injury are also fewer. It is reasonable to infer from these figures that increasing care is exercised in working the traffic, and that means and appliances are introduced which tend to make railway travelling safer, at the same time reducing the risk of accident from other causes which stand in some relation to the traffic. In the case of the passengers, it is a matter for congratulation that while the number carried in 1893 was several millions greater than in the previous year, the proportion of passengers killed, from all causes, was changed from one in 6,700,000 to one in 8,237,000.

In the working of the trains, an important aid to safety is to be sought in the absolute block and interlocking systems. Of 19,499 miles of line open to passenger traffic, over 18,000 miles are now worked on the absolute block system. The proportion in which the signal and point levers have been interlocked is 99 per cent. for England and 98 per cent. for the whole of the United Kingdom. While the companies are rendering better service to the public than at any previous period, it is to be regretted that the profits of the undertakings, taken as a whole, have undergone diminution. As pointed out by Mr. Giffen and Mr. Hopwood, there has been a decrease in the net amount earned and available for distribution among the railway shareholders in each of the last four years in succession; but the decrease last year far surpasses that in each of the three previous years, as it does also the decrease in any year since anything like accurate information has been obtainable. The retrogression is shown by the circumstance that in 1889, when the net earnings were the highest on record, the amount reached was nearly £37,000,000, whereas last year it was under £35,000,000, the falling-off being nearly £2,000,000. There is also the further disadvantage that these diminished earnings have to be spread over an enlarged capital. The real increase of railway capital last year, apart from the nominal, is shown to be about £17,000,000. It is computed that the amount paid in dividends to ordinary shareholders in 1889 was £15,210,000; whereas the corresponding amount last year was only £12,400,000, a reduction of £2,810,000, or fully 18 per cent., while the capital account had increased by about £28,000,000 during that period. The public expect great things from the railways, but the shareholders are reaping a slender reward, while those who travel are daily receiving greater advantages and are looking for more.

### BRIGHTON BEACH.

When writing our last article about Brighton beach the public at large was wholly unacquainted with the fact that the Brighton Town Council were then awaiting a report and proposition with respect to the further sea defences of their town from their engineering advisers. Brighton has learned, however, that these have, during the last few days, been submitted to the Council, and that as the result it has been determined to expend a sum of no less than £47,000 upon the defence and additional ornamentation of the sea frontage of the town. The resolution so come to is possessed of a particular interest for ourselves. The work now proposed to be undertaken embraces to a very great extent the principle we have throughout our series of articles on this subject advocated as being the only one on which full security could be obtained. At the same time that the Council and its advisers have thus very largely endorsed our views, we do not feel altogether assured that the works contemplated are of the complete character that is, in our judgment, to be desired, for in some degree we feel that they are of the nature of a compromise. Compromises, as we know, are rarely wholly successful: they may include all that is best in schemes of a more thorough-dealing character, or they may embody only that which might deservedly be rejected. Before, however, entering upon any discussion of what has been resolved upon, it is desirable to give an outline of the main features of the new scheme. Turning our attention first of all to the eastern extremity of the town, we would remind our readers as to the stress we have laid upon the dangerous condition of the cliffs at Black Rock, to which subject we devoted more than one separate article. Naturally this matter is one the consideration of which has for some years been forced upon the municipal authority. Of the repeated accidents taking place at this point, and of the serious consequences involved to the drainage works of the town, we have fully informed our readers. We see no reason to dispute the sufficiency of the course now resolved upon in order to secure this locality from further damage. Adopting our view that groyning, under the changed conditions of the flow of the shingle brought about by the erection of the sea wall at Hove, would be insufficient to meet the case, it has been determined to erect a massive sea wall well in advance of the foot of the cliff. Within the line so to be attained an extension of the present Madeira-road is to be formed, a boon which the inhabitants of the east end of Brighton will certainly appreciate. This design is to supersede one presented to the Council only last year which made provision for the construction of three groynes, 150ft., 250ft., and 600ft. in length respectively. In place of the central of these three groynes, a sea wall is now to be built, the other two being retained to aid in the deposit of beach along the face of the wall, one being 350ft. long and the other 500ft. This new sea wall, the intended length of which has not been stated, will have its top 12ft. 6in. above high-water mark, the thickness at its summit being 6ft. The space to be recovered from the foot of the cliff, and that will be available for the extension of the Madeira Drive, will be 60ft. in width. The estimated cost of this portion of the general scheme is £14,000, the material of the wall being of concrete with flint-facing blocks.

Passing westwards, the next section to be dealt with is the extension of the present raised terrace below which are shelters and reading-rooms. This extension will increase the length of the existing handsome erection by 1530ft., and sloped ascents will be provided whereby Bath chairs can reach this intermediate level between the upper and lower parades. Of course this work does not come within the category of the defensive works we are now immediately considering; but as being part of the general design decided upon, it seems to be desirable not wholly to omit reference to it. The estimate for this work is also £14,000.

It is when we arrive at the third and last proposition that we reach the point to which we have in our former articles mainly called attention; for it has been on this section of the foreshore that the effects of the sea wall at Hove have shown themselves most seriously. When remarking in our recent article upon the result to the extensive groyning that has, during the past few years, been added between the end of the Hove wall and the West Pier, we observed that the character of the limited amount of shingle arrested by it was not such as to promise the required degree of permanent lodgment. The shingle, as we have always foreseen that it must do, passes in its present line of travel too far seawards to admit of its arrest by the new groynes, which, although of very considerable length, do not reach that line. We have from the very moment that denudation threatened this section of the sea frontage, expressed our opinion that a sea wall would be necessary, and that the expenditure on mere groyning would fail of its hoped-for result. Apparently, conviction in this sense has now been forced upon the local authorities, and we learn that a sea wall, about 1620ft. long, is to practically connect that built at Hove with the large concrete groyne just eastward of the West Pier. This will, however, be of a different character to the massive wall built at Hove. It is intended primarily to serve as a base for now existing groynes and for the additional one contemplated with the object of reaching the hitherto unattained line of shingle travel. In addition to this function, the wall is to serve as a retaining wall for the extra land to be added to the existing lawns, provision being made whereby interference with the present facilities for boating and bathing will be avoided. In our last article we suggested that means could be found whereby this interference might be provided against. The space to be recovered by this wall will give an additional width of 30ft. to the gardens. The slipway for boats is to be maintained as now provided between the Hove wall and that proposed, and is to be defended by a timber breastwork 100ft. long, but how this is to be constructed we have learned no detail. A further additional concrete groyne is to be built opposite to Preston-street, and sundry additions made to those others constructed within the last few years. The cost of these new works and alterations has been estimated at £18,894 7s., bringing the total for all the three sections we have dealt with to the sum of £47,000.

We have above referred to these several works as seeming to us to be to a great extent of the nature of a compromise between what we have ourselves expressed as being necessary and the system upon which the Town Council has hitherto solely relied. But although this is so, we feel that our previous contention receives a large amount of endorsement under the new scheme, this being the result of a protracted and very costly experience of failure to that system. We are not blind to the distinction that has to be drawn between the wants of Hove and those of Brighton influencing the decisions now taken. Hove consists largely, and mainly, of residential property, the occupiers of which are by their tastes independent of the ordinary amusements sought for by visitors to the neighbouring borough. For these last a beach, with its somewhat vulgarised entertainments, is the chief attraction. The maintenance of a wide stretch of this is, therefore, in the case of Brighton, more of a necessity than it is in the instance of Hove. This distinction was brought out very forcibly during the discussion by the Town Council of Brighton of the schemes just submitted to it. Hove cares only for quiet recreation for its inhabitants; Brighton visitors for the most part are attracted by the rather noisy elements suited to the excursionists who throng daily during the season the fine parades and foreshores of the town. It is for this reason—and for this reason only perhaps—that the Town Council supports a compromise between full and partial efficiency. For this its members can hardly be blamed. The sea wall resolved upon by them must certainly form an efficient second line of defence, but it will not be—if the hope of securing shingle be realised—the first and permanent line of defence that the Hove wall is. It is the hope of the Council, in fact, that ultimately even the top of the new wall will become covered with shingle. This anticipation may be justifiable, but it is one that should not be too confidently entertained. We only hope that, with too great a reliance upon it, it may not be attempted to make the new wall of a strength insufficient to withstand direct attack by the sea in the event of its possible non-realisation. But should this required strength be given, the principle we have so persistently advocated will have been at least admitted, and a large amount of ultimate, if not first, security attained.

Nevertheless, it is greatly to be feared that the endeavour to adhere in part to a system of multiplying groynes will result in the almost total spoiling of this part of the beach for the objects it is desired to secure. The remedy may almost prove to be worse than the disease, for when last writing we remarked upon the unsightliness and splitting up of the beach into uneven levels caused by what has already been done in this direction. We even doubt, as we have before done, whether the multiplication of these high and costly concrete groynes can be justified. If the line of shingle travel can be reached, a few years would probably establish a beach firm enough to withstand all future attack. When once so established there should be little or no tendency to resume travel, and timber groynes would have acted as efficiently during those few years as would the high and more expensive ones of concrete, while the beach formed would be less inconveniently broken up than it must be by the latter. Of course the peculiar conditions we have named as ruling the decisions of the Town Council in this matter do not apply to the protective works decided upon at Black Rock. Here the intended sea wall will be the first and the only line of defence, and it will therefore differ materially in character from that we have named as contemplated for the western works. Probably some result may follow the construction of the two groynes to be built in connection with this, and some shingle may accumulate to protect the foot of the wall. But in that particular locality addition of beach is not required for pleasure purposes, and the wall might be left to fulfil unaided its intended function. Hence we cannot see why one at least of these groynes might not be done without, unless, indeed, it is wished to protect the line of coast eastward beyond the limits of the town's jurisdiction and responsibility. But it may possibly be thought desirable to proceed in that direction in view of the fact that the main drainage outfall of the town lies considerably to the eastward of Black Rock, and already shows signs of being affected by the fall of cliff in its neighbourhood. On this ground we should not feel disposed to dispute the wisdom of constructing the groynes, although on others we should deem one of them at least to be superfluous.

We congratulate the Brighton people on at length showing themselves alive to their great and increasing responsibility in this matter. Time alone can demonstrate if the new western work, when it has achieved—if it ever does—the success hoped for from it, may not be productive of renewed injury on other parts of their sea frontage. Neither do we note in the details of the scheme resolved upon any allusion to the denudation now going on in the neighbourhood of the old Chain Pier. We remarked upon this when last directing attention to the subject, but it is possible that the estimate for the improvement of the Madeira Drive may include provision for the required defensive work at this point. It is only to be regretted that the principle of building sea walls has been so tardily accepted. Had it received adoption earlier, very serious expenditure would most probably have been saved to the already heavily burdened ratepayers of Brighton. We are ignorant of the engineering authority that has been consulted as to these intended works, but it should be evident that a true economy would dictate that it should be of the highest and most experienced standard.

◆

### THE CO-OPERATORS IN CONFERENCE.

The Co-operative Societies in the South Yorkshire district held a conference of delegates at Kilnhurst, a colliery district, last Saturday. The conference, which was unusually representative, was mainly important for some plain speaking on the part of the more intelligent and clear-seeing of its members. Some of the remarks made are so sensible and so unusual at workmen's gatherings that they deserve more than local notice. A paper was read by Mr. T. Whitfield. of Kilnhurst, on "The Co-operative Movement and How it can Help on the Principles of Trades Unionism and Socialism." His reply to the question, "How can we reach the poorer classes?" was the extension of what he called "the great social principle of co-operation." Fifty years ago twenty-eight pioneers represented all under that banner. Now there is an army of 1,240,013. Their dealings had swelled into £50,318,977 annually, and the slender capital of £28 had grown into £14,013,687. These are noteworthy figures, but the comments by which they were accompanied are more noteworthy still. Mr. Whitfield disclaimed all sympathy with that system of socialism which implied "dead level uniformity and perfect equality," contending that equity was not the same thing as equality, and pointing out that the early co-operators had the instinct of equity in their hearts. His plain doctrine of social regeneration, was that they must raise the moral character, elevate the social tone and domestic tastes, make a man more self-reliant and self-reflecting. He deprecated the attacks of labour upon capital, holding that co-operators were not haters of capital, but creators of it. Other speakers were even more pointed in insisting upon the necessity of working men looking to themselves more than they did for their improvement. The Chairman of the Sheffield district declared bluntly that working men had the matter largely in their own hands as to their own happiness and prosperity, and that "it was possible for them to work out their own salvation." Another Sheffield gentleman was strongly of opinion "that it was not a revolutionary spirit that was needed, but a reasonable and conciliatory spirit, rather than flying in the face of their employers." Mr. Hall, a miner, pronounced boldly against both strikes and lockouts, and another miner said he was convinced they would all be acting very wisely if they spent their capital by being their own producers, rather than let it go to strikes and lockouts. Mr. Scotton, who is represented as "of the wholesale department," spoke vigorously against the foolish system of working men wasting their money in fighting capitalists. "Certain leaders," he said, "were constantly denouncing the capitalists, and yet these very individuals were charging large amounts to attend meetings and speak. These persons were becoming capitalists as fast as possible, and when these leaders had 'feathered their own nests' it would be good-bye to the working men whom they had duped. Talk about Parliament helping working men, if they would not help to raise themselves they never would be raised." These and other healthy utterances appear to have been taken in a friendly spirit. It is to be hoped that working men will continue to receive equally wholesome advice from their own order, and come at last to act up to it, particularly in the direction indicated by the Masbro' delegate, who candidly declared that working men were deficient in self-reliance and the virtue of economy. When they got good wages they did not know how to take care of them, and were "too much in the habit of visiting the Black Bull and the Red Cow."

### NINE MONTHS' CLYDE SHIPBUILDING.

For the nine months of the year now completed the output of new shipping on the Clyde amounts to 252,100 tons, a figure which has only been surpassed for the same period twice during the past decade, viz., in 1892, when the nine months' output reached 275,935 tons, and 1890, when it was 256,333 tons. Notwithstanding the fact that operations have been considerably handicapped on account of the miners' strike, the output during September is comparatively large, being not less than 19,295 tons over the production of September of last year. Altogether twenty vessels, measuring 38,070 tons, were placed in the water, as against sixteen vessels, aggregating 18,775 tons, in the corresponding month of last year. The vessels launched consisted of two war vessels and fourteen steamers, measuring 30,370 tons, and four sailing vessels of 7700 tons. Seventeen were for British owners, one for German, one Brazil, and one for San Domingo. Five of the new steamers measure over 5000 tons each, and include the Strathgyle of 7350 tons capacity, launched by Messrs. Russell and Co., Greenock, for Messrs. Burrell and Sons, of Glasgow; the Orestes of 6400 tons capacity, launched by Messrs. Scot and Co., Greenock, for the Ocean Steamship Company, Liverpool; the Planet Venus, 5600 tons, by Messrs. Hamilton and Co., Port Glasgow, for a Liverpool firm; and a vessel unnamed, of 7000 tons capacity, launched by Messrs. A. and J. Inglis, of Pointhouse. A number of important contracts have been placed during September, the new work secured representing nearly 30,000 tons, as compared with 24,000 tons last September. The orders include four steamers of 4500 tons each for the Peninsular and Oriental Steam Navigation Company—three to be built by Messrs. Caird and Co., Greenock, and one by Messrs. Alexander Stephen and Sons, Linthouse. The continuance of the coal strike is still having a retarding effect on the work in the various shipyards, for the firms are unable to procure adequate supplies of constructive material to meet their requirements. At Clydebank, Fairfield, and Govan, where there are important Government orders on hand, labour is much delayed, with the result that the builders have been compelled to suspend many hundreds of workmen who would otherwise have been employed.

### THE COMING AMERICAN TRANSATLANTIC LINERS.

From authoritative statements emanating from the "American Line," it would now appear that, contrary to the statements appearing in American papers, and repeated by many journals on this side, it is not at all the intention of the American Line to make any effort in their new steamers, St. Louis and St. Paul, building at Messrs. Cramps, of Philadelphia, to beat the Cunard Company's Campania and Lucania in the matter of speed. The management of the American Line are satisfied—and have been from the first, one is left to infer—that the speed and power of the Paris and New York will be ample for every requirement of the Transatlantic service for years to come, without going to the extraordinary expense and size of the Cunard steamers, which, it is pointed out, have to be taken off the service in the winter. When they are in service, it is maintained, it not infrequently happens that they have to wait outside the harbour until the tide accommodates them, while the New York and Paris go right to their berth at New York when they arrive. The St. Louis and the St. Paul, therefore, are to be mates of the Paris and New York as to speed, being about the same size and having the same power. The builders, it is authoritatively admitted, have in large measure followed the model of the Clyde-built vessels, but in some respects the new steamers will even excel those vessels. This, we understand from a good source, will hold true as regards the saloon and passenger accommodation; some arrangements connected with the dining, cooking, and commissariat departments—based on experience with American river passenger steamers, and quite novel on the Transatlantic service—being a feature in the new vessels. They will be launched next month, it is stated, and will be ready to join the line between Southampton and New York in the coming year.

### EALING ELECTRIC SUPPLY WORKS.

The town of Ealing has long been accustomed to take the lead, among modern English towns of rapid growth, in several matters relating to sanitary engineering, and every surveyor and borough engineer who has ever had to consider the problems relating to sewage treatment and town refuse disposal is familiar with the work by which the name of Mr. Charles Jones, M. Inst. C.E., the borough engineer of Ealing, is associated with these branches of engineering. To its already existing accomplishments Ealing has now added that of public electric lighting of streets and public buildings, by means of works which have been carried out from the designs and under the superintendence of Messrs. Bramwell and Harris. When it became necessary to permit a company to undertake the lighting of Ealing, or to take the work in hand as under a Provisional Order, the Ealing Board decided upon the latter course, and the necessary sum of £25,000 was borrowed forthwith to carry out the scheme devised by Messrs. Bramwell and Harris. The area to be lighted is a large one, and the number of lights, in comparison with the distances served, rather small under the best circumstances. As compared with the cost of gas, and as a matter of trade for shops and other lighting, there is, however, no doubt that the works will soon earn a profit to the benefit of the ratepayers, and indeed it is already obvious that the works will have to be extended. They were formally opened on Wednesday evening by Mr. E. M. Nelson, J.P., as chairman of the Board, and a dinner was afterwards given in the Lyric Hall, at which the members of the Board, the eminent engineers and the contractors were entertained. The works are in several respects similar to those carried out under the same engineers and so successfully lighting the town of Derby. The engines are by Messrs. Browett and Lindley; the dynamos, continuous current for arc and alternating for incandescent lighting, and the transformers and switches are by Messrs. Siemens Brothers; the boilers, Lancashire, by Messrs. J. Watt and Co., Birmingham; the street mains, by Messrs. Callender and Co.; and the surface condensers are to be by Messrs. Belliss and Co. The latter are to receive as circulating water the effluent from the sewage works, and the boiler power is to be supplemented by the batter of refuse destructors which are so well known as an important part of Mr. C. Jones' work. The buildings have been erected by Messrs. Wilkinson Brothers, Finsbury Park. The whole of the works have been carried out in a remarkably short time, although the area of supply is a very large one.

## LITERATURE.

*Coal Dust an Explosive Agent, as shown by an Examination of the Camerton Explosion.* By Donald M. D. Stuart, F.G.S. Office of the *Colliery Manager*, London. 1894.

Mr. Stuart has given us an accurate, and therefore valuable, description of an explosion which occurred at the Camerton Collieries, situated in the Radstock district. The part of the colliery where the explosion took place was worked in three eight-hour shifts, of which the eight hours from 8 p.m. to 4 a.m. were occupied in repairing and road making. On November 13th, 1893, two men were sent down to blast the roof of an incline, to make height for the loaded trams to pass under, and an explosion or series of explosions took place, by which the men lost their lives and much damage was done to the underground workings. The seams in the district had been worked for about a hundred years, and fire-damp had never been detected "in either the coal faces, the goaves, or the faults." Naked lights only were used, and no danger from an explosion was apprehended. The minute examination of the mine after the accident, so clearly recorded by Mr. Stuart, shows without doubt that the calamity was caused by coal dust. The danger of coal dust in fiery mines has long been known. Recently the subject has been carefully studied, and is now being inquired into by a Royal Commission. The experiments made by Mr. H. Hall, H.M.'s Inspector of Mines, for this Commission have demonstrated that, under certain circumstances, coal dust alone will explode in presence of a gunpowder shot; and Professor Dixon, in his report on the recent explosion at the Albion Colliery, states as his opinion that this was a pure dust explosion. But then the coal dust from the Albion Colliery was found by Mr. Hall to be specially fiery, whereas the "dust from the non-gaseous mines of Gloucestershire and Somersetshire proved to be inexplosive agents." The surroundings at the Camerton Colliery were opposed to the probability of an explosion taking place. There was no fire-damp in the mine, the dust had been tried and found non-explosive; and "the main roads are to a large extent in solid strata, and as a rule they retain more moisture than those in the seams; and their own *débris* and dust are of an argillacious and incombustible character." How, then, did the explosion occur? The actual ignition is closely traced to a partially blown-out shot, fired with about 12½ oz. of gunpowder. Mr. Stuart calculates that the temperature of the products of such a shot would be 2896 deg. C., which would be not only sufficient to liberate the gas out of the coal, but also to decompose it. The gaseous products would then, in the presence of great heat, take fire, and an explosion would follow. Referring to the evidence of high temperature, Mr. Stuart describes the effect produced at No. 2 refuge-hole, about fourteen yards from the shot, "where there was a calico bag, containing the food of one of the deceased men firmly suspended by an ordinary cotton tape from a timber roller in the roof. This bag was found still hanging after the explosion, but the texture of the material was changed—the fibrous structure and tensile strength were destroyed." This seems to indicate that the bag had not been exposed to the action of flame, but only to intense heat. The men were found in a refuge-hole thirty-five yards from the shot, and, according to the medical report, death was owing to severe burns. Mr. Stuart says:—"Flame of sufficient persistency to effect burns of such a nature must have consumed all the hair upon their heads," whereas it was only singed. The theory adopted by Mr. Stuart to explain this explosion is that the heat from the blown-out shot was sufficient to decompose the gaseous products of the coal dust, and that the explosions were due to the liberated hydrogen of the marsh-gas. The ten explosions which were traced were separated by intervals varying from 45 to 460 yards, and it is scarcely probable that flame travelled those distances. It must therefore be admitted that a separate motion took place.

With reference to the action of flame in explosions of hydrocarbon, it may not be out of place to quote Mr. Boverton Redwood, who, in a paper recently read before the Institution of Civil Engineers, says: "There are several cases on record of so-called 'spontaneous' explosions of benzoline vapour"—which indicates that a hydrocarbon vapour or gas may ignite without the presence of flame.

There is another point which must be taken into account to explain the possibility of an explosion of coal dust in a district where circumstances similar to those attending the accident at Camerton had prevailed for many years—namely, the ventilation of the colliery had recently been improved, and a greater current of air forced through the workings than formerly; and therefore it is most probable that the coal dust would be desiccated and carried up by the current to a greater extent. The coal is used for gas making, and yields 11,134 cubic feet of purified gas per ton, and would, in presence of heat, give out a considerable quantity of inflammable gas.

It is already demonstrated that, in coal mines giving out fire-damp, the use of gunpowder is quite unsafe; that the presence of coal dust enhances the danger; and that the only explosives which ought to be used under such circumstances are the so-called "high" explosives. Now, it appears that a shot fired in an atmosphere absolutely devoid of explosive gases, but holding in suspension a certain proportion of fine and dry coal dust, may be the cause of an explosion. We cannot help observing that the coaldust danger is directly connected with the great velocity of the ventilating currents in modern collieries, which carry with them a constant danger in the clouds of dust, for which some remedy must be found. The most obvious would be the absolute prohibition of all explosives in coal mines. This drastic measure would, however, entail a considerable rise in the cost of working coal.

Mr. Stuart has written a most valuable addition to the series of records relating to the important subject of danger from coal dust. We cannot, however, agree with him when he states that:—"The records of mining show that explosions cause greater destruction of life and property than any other class of accident."

Death of Mr. John Hastie.—We regret to have to record the death, on the 22nd inst., of Mr. John Hastie, partner of the firm of Messrs. John Hastie and Co., Kilblain Engine works, Greenock, the well-known makers of ships' steering-gears, winches, &c. Mr. Hastie and his brother succeeded about twenty-three years ago to the engineering business in Greenock established about 1850 by their father. Mr. Hastie served his apprenticeship with his father, and afterwards worked in some of the leading engineering establishments in Glasgow and Manchester. He was a man of considerable inventive talent, particularly in connection with hydraulic engineering, including the well known and ingenious capstan engine with the variable throw crank. He was the author of several interesting papers on engineering subjects, which he read before the Scottish Institution of Engineers and Shipbuilders at their meetings in Glasgow. Mr. Hastie was slightly over 50 years of age.

# DYNAMOMETRIC CAR, WESTERN OF FRANCE RAILWAY

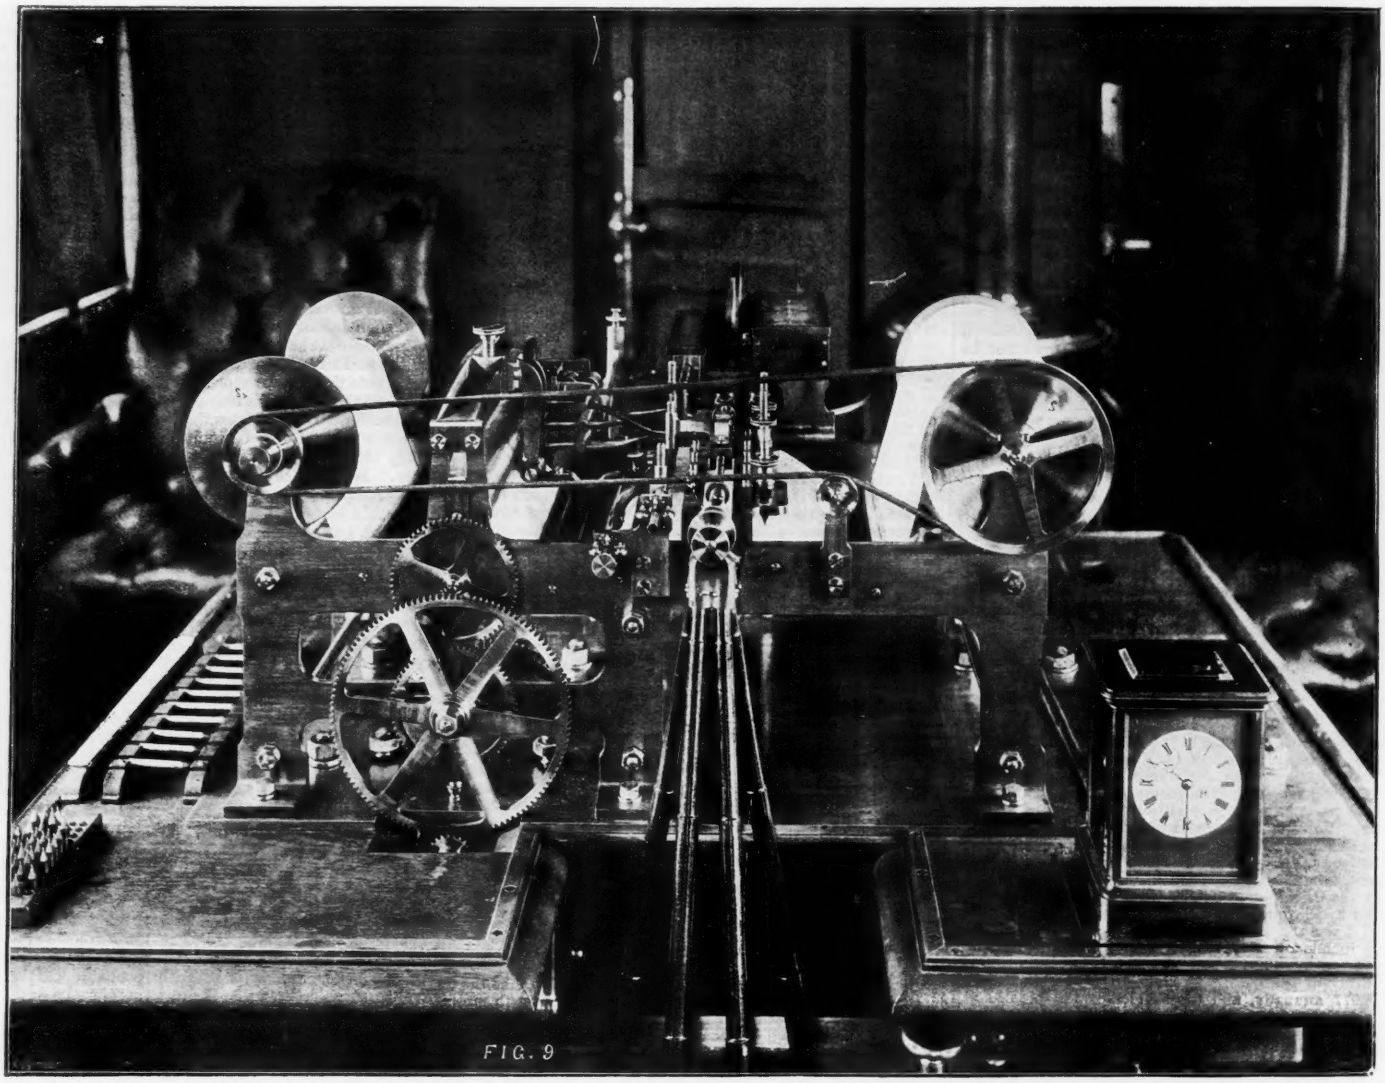

FIG. 9

## A DYNAMOMETRIC RAILWAY CAR.

The particular dynamometric railway car which we are about to describe is the property of the Western of France Railway Co. Our special attention has been attracted to its employment from the fact that it has been used to record the performances of the Heilmann electric locomotive, which we described in our issue of February 9th, 1894, page 109. We learn that the locomotive has been in regular service between Paris and Mantes, and we hope shortly to be in a position to give a detailed account of the results obtained, and to compare them with those from the ordinary steam locomotives performing similar duty upon the same line. The car is designed to afford a means of recording the speeds attained during a given trial, the pull upon the draw bar, the total power developed, and other interesting facts. This car was exhibited at the Paris Exhibition of 1889, and since that time two similar cars have been built for foreign railway companies; one for the Russian South-Western Railway, and the other for the Hungarian State Railways.

The general programme of what was required was laid down by Mr. F. Clerault, engineer-in-chief of the Western of France Railway, and the details were worked out by Mr. E. Gauthier, chief of the central service, in concert with Mr. Digeon, manufacturing engineer, of Paris. We give upon page 305 a number of sectional drawings of the vehicle, and also Figs. 9 and 10, above and on p. 297, which are reproduced from photographs, showing the interior of the car with the recording mechanism. The car is carried upon two axles, and a special coupling arrangement is employed to eliminate the influence of curves while permitting the buffers to make contact; for this purpose the buffers are connected to a transverse bar, which rests at its centre upon a group of rubber washers. Upon the platform at the end of the car a trap door is arranged, so that the dynamometer may readily be put in or out of gear. At each side of the entrance door is a raised seat, from which an attendant can observe the track, train, and locomotive, and have within reach electric press buttons to note upon the diagrams particular points upon the roads, also a speaking tube to the locomotive, and apparatus for the purpose of collecting gases from the chimney. Under the seats are arranged the Orsat apparatus for gas analysis.

Outside the end windows are placed inclined plates to prevent the deposit of dust and soot upon the glass. In the centre of the car is placed a table, upon which are collected all the recording apparatus described below. At one end of the vehicle there is a lavatory, and also a workshop in which any slight necessary repairs may be done while travelling. The car is heated by means of a small stove, and ventilation is assured by means of two Pignatelli apparatus, one opening above the end windows and the other in the ceiling of the central compartment. The results obtained in each particular trial are all recorded upon a single band of paper which receives its motion from the axle of the car, and is unrolled continuously during the journey proportionally to the distance covered. All the recording apparatus also is put into action by the car itself. Referring to the engraving on page 305, it will be seen that a worm V is keyed upon the axle, a worm wheel X gears with it, and transmits motion to a vertical shaft Z through two bevel wheels. The spindle Y is provided with a Hooke's joint to allow for play of the axles. The apparatus can be put in and out of gear from inside the vehicle by turning the screw K, and so raising the wheel X, the bearings of which can slide in collars which surround the screw V. The bearings are connected by a cross-piece provided with a tapped hole, in which the screw K works. The upper end of the screw rod is fitted with a worm wheel K$^1$ at the top of the pillar, and this wheel is controlled through a worm by a handle. At the top of the vertical spindle Z is fitted a set of bevel wheels, with a Dobo driving clutch in each; this gear is shown on a larger scale in Fig. 5, and causes the paper to move in the same direction, whichever way the train is travelling. The bevel wheels E′ E″ set the main spindle T in rotation at a speed precisely the same as that of the axle O of the car. From the shaft T are taken all the different movements of the recording apparatus; for example, the traversing of the paper, and that of the disc for totalising the work. The movements for the screw and for the tachometer are, however, taken off an auxiliary shaft N, which is driven by the wheels D$^1$ and D$^2$. A clutch Θ, acting by friction and also through teeth, and placed upon the spindle T, allows all the motions of the recording apparatus except the screw *a* to be stopped, in order to be able to constantly observe the speed of the train, by means of a graduated scale placed upon the controlling rod $t^1$ of the pencil 3. The action of the clutch takes place gradually, whatever be the speed of the train; at first by friction alone, and afterwards by the teeth, which ensures the constant relative position of the two parts of the spindle T. A second auxiliary shaft T$^2$ has been put in, so that it may be used if required. It will be noted that all the gearing is below the table, and that therefore there is no danger of an accident while attending to the recording apparatus above the table.

*Tractive effort.*—The pull on the draw bar only is measured, as it is considered that this is all that is required to compare loads which can be drawn by different engines. The measurement is made by means of a dynamometer, shown in section in Fig. 1, and in plan in Fig. 3, and composed of two groups of flat springs, the ends of which are linked together two and two and form a rigid stirrup with the frame. This arrangement is used to ensure the proper relative positions of the groups of springs. The head C of the forward part of the dynamometer is joined to the draw-bar at the end of the car next to the locomotive, and this bar is guided between horizontal and vertical rollers to avoid cross-cornering, due to the passage round curves and to side play. This bar has also a knuckle joint at *w* to allow for the swing of the draw-bar, and no appreciable friction is felt upon the connecting bar.

The head C$^1$ of the rear end of the dynamometer is fixed to a cross beam of the frame. The head C, which moves under the action of the locomotive, is mounted upon a carriage B, which rolls upon three small wheels resting upon an iron plate placed in a horizontal plane and carefully trued up. Upon this same carriage are fixed the four columns of the pencil carrier P; these columns formed of steel tubes are very light and are at the same time very rigid. The end P of the pencil carrier, which forms the head of the four columns, actuates by means of a rod *t* provided with a double knuckle joint a pencil 1 mounted upon a piece which is guided in a slide, besides this there is an opposing spring *f* which acts through a flexible band passing in the groove of a pulley $f^1$ upon an extension of the rod *t* and neutralises the play which might take place in the knuckle joints. The pencil registers the pull on the draw-bar upon a band of paper, which is unwound proportionally to the spaces traversed. The complete dynamometer spring has a flexibility of 0 63in. per ton, and can measure up to a maximum of 7·5 tons. The bending of the dynamometer spring is transmitted full size to the paper, and besides this a fixed pencil 7 traces continuously a base line corresponding to the zero position of pencil 1. It is thus easy to obtain the effort on the draw-bar at each moment.

*Total work.*—In order considerably to reduce the labour of calculation, the work is measured and totalised by an apparatus with disc and roller, shown in Figs. 1, 2, and 4. It consists of an elongation of the rod $t^1$, which transmits the movements of the pencil carrier to the pencil 1 for recording the pull on the draw-bar, and upon this elongation is mounted a fork which moves a roller *m* in a corresponding manner to the pencil, and this roller is kept in contact with a disc *p* by means of a spiral spring *r*, the tension of which is adjustable by means of nuts *v* mounted like the spring *r* upon the spindle of the disc. The spindle upon which the roller *m* moves is parallel to the rod *t*, and passes through the centre of the disc *p*, and the latter has a speed of rotation proportional to that of the axle of the car. When there is no pull on the draw-bar the roller rests at the centre of the disc, but when there is a pull on the bar the roller moves away from the centre and turns on its own axis. The number of turns made by the roller—of course depending upon the distance of the roller from the centre of the disc—is a measure of the work done to a constant scale, which is a function of the diameter of the roller. In this particular machine one turn of the roller corresponds to 72,330 foot-pounds; it is therefore sufficient to record the number of turns of the roller to obtain at each instant from the datum line the work developed. For this purpose a revolution counter is fitted up in connection with the spindle of the roller, and the total work can be read off at once in foot-pounds. It was, however, desired to have also a record of the total work upon the paper bands, and to allow of this the spindle of the roller actuates a cylinder, *d*—Fig. 8—upon which is cut a screw-thread, which is continuous and closed on itself. In this thread runs a kind of roller of suitable form which moves a rod, carrying a pencil 2, pressing upon the paper band. The whole apparatus is so designed that the roller gearing with the thread moves from one end of its course to the other for each sixty turns of the roller on the disc, the pencil therefore traces a kind of sinusoidal curve

between two parallel lines, 2·36in. apart. The ordinate to each of the summits of the curve corresponds to 72,330 × 60 = 4,339,800 foot-pounds. An ordinate to the curve from an intermediate point will give to a certain scale the work developed from the last summit.

*Speed.*—The speed is measured by an apparatus giving a record proportional to the speed of the train. Upon a horizontal disc, Fig. 6, rests a roller *m* mounted upon a screw *d*, with its axis parallel to the plane of the disc and vertically above one of its diameters. The disc obtains a constant and uniform rotary movement from a special governor, and in this special car makes 180 turns per minute. The screw obtains rotary motion from the principal shaft of the apparatus. The directions of rotation of the screw and the disc are so arranged that the movement of the screw causes the roller to move away from the centre of the disc, and at the same time the disc causes the roller to turn in the same direction as the screw upon which it is mounted, and therefore in case of a stop it brings back the roller to the centre of the disc. It is therefore obvious that the roller will always move away from the centre of the disc until a point is reached where the speed of the disc exactly counteracts the speed of the screw, and at this point the roller will remain fixed so far as distance from the centre of the disc is concerned, and this radial distance is a measure of the speed of the train. Pencil 3, which is connected to the roller, records the curve of speed upon the paper band. The second disc, which turns in a contrary direction to the disc *n*, is used to ensure proper contact with disc *n*.

*Record of revolutions of the wheels.*—The number of turns of the wheels are recorded by pencil 4 actuated by an electro-magnet $\epsilon$. This electro-magnet is placed in a circuit, which is closed each ten turns of the wheel by a commutator *f*, mounted on a spindle *b*, geared to the spindle T, which makes the same number of revolutions as the axles.

*Time.*—The time is registered by means of a clock with electrical contacts H, by means of which a current is sent every ten seconds into an electro-magnet $\epsilon'$. The latter actuates a pencil 5, which traces six notches per minute upon the paper band.

*Distance record.*—Pencil 6 is moved by an electro-magnet $\epsilon''$, into which a current is sent by means of press buttons placed upon the front end wall of the car, close at hand for the attendant, who is thus able to note the kilometre posts passed and any other interesting points on the route. A printing mechanism $O_3$ figures the number of each post as it is passed.

*Datum lines.*—Fixed pencils, which can be regulated by hand, trace upon the travelling band base or datum lines, pencil 7 effecting this for the draw-bar pull, and pencil 8 for the speed.

*Delivery of the paper.*—The paper band, which is wrapped upon the cylinder $S^1$, is drawn out by the roller X, with which adhesion is maintained by the pressure of roller $x^2$, and the paper winds on to roller $S^2$. The latter is driven by the cylinder $S^1$ by means of an endless band passing over a pulley $O^1$ fixed to the shaft of the latter cylinder, and over a smaller loose pulley $O^2$ mounted upon the shaft of the cylinder $S^2$. By means of a friction clutch regulated by a screw, the loose pulley can be driven so as to allow a certain amount of slip, and thus regulate the tension on the paper band in spite of the changing diameters of the rolls $S^1$ and $S^2$. The paper leaving roller $S^1$ passes beneath some small rollers *s*, then over the table $T_a$, upon which the pencils work; thence it passes under another little roller *s* before passing between rollers *x* and $x^2$, and finally, after passing under a small roller *s*, it is rolled on roller $S^2$.

*Gas analysis.*—The analysis of the products of combustion is effected by two sets of Orsat apparatus placed below the observation seats. The analysis consists of measuring the percentage of carbonic acid, carbonic oxide, and oxygen. The residue is supposed to consist solely of nitrogen. A copper tube is suspended from the top of the locomotive chimney, and is connected by india-rubber tube to a fixed flask into which the gas is drawn by an aspirator. The volume of gas to be analysed is passed into a graduated tube, and then passed into test tubes containing absorbents. The first tube contains a solution of caustic potash, which absorbs the carbonic acid; the second contains a solution of potassium pyrogallate which absorbs the oxygen, and the third tube a solution of cuprous chloride which absorbs the carbonic oxide. After each absorption the gas remaining is measured in the graduated tube, and the volume absorbed is the difference between the first and last measurements. The final residue is considered as nitrogen. On page 305 we give to a reduced scale a record of results obtained upon the Western Railway of France between Paris and Neuchatel, and we hope shortly to publish the actual results obtained in the regular service of the Heilmann locomotive when working between Paris and Mantes.

### DESCRIPTION.

*Measure and record of draw bar pull.*—C movable head of the dynamometer coupled to the draw bar A; $C^1$ fixed head of the dynamometer; $\omega$ knuckle joint of the bar A; B movable carriage supporting the head C; P pencil carrier transmitting the movement of the head C to the rod *t*, held back by the spring *e*.

*Record of the total work.*—*m* roller recording the work and moving with the rod *t*; *p* plate for roller *m*, having a speed equal to that of the axle E; $C^1$ counter of revolutions of *m*; 2 pencil recording work developed; *d* cylinder with closed screw thread.

*Speed recorder.*—$\alpha$ screw on axle E; M clockwork imparting uniform motion to plate $\pi$; M roller forming a nut and mounted on the screw $\alpha$; 3 pencil recording the speed and controlled by the roller M.

*Revolution of wheel counter.*—4 pencil recording the tens of turns of wheels; $\epsilon$ electro-magnet moving pencil 4 and placed in a circuit closed by switch *f*; *b* shaft carrying the switch *f*.

*Time recorder.*—H clock sending every ten seconds a current into electro-magnet $\epsilon^1$; 5 pencil controlled by the electro-magnet $\epsilon^1$ and making a notch every ten seconds.

*Kilometre record.*—6 pencil moved by an electro-magnet $\epsilon''$ into which the current is sent by a press button.

*Datum lines.*—7 pencil tracing the datum line for draw bar pulls; 8 pencil tracing the datum line for draw speed.

*Transmission of motion.*—V worm upon the axle of car; W pillar supporting wheel $K^1$ controlled by worm and handle K″; K screw controlled by wheel $K^1$; T principal shaft driving the recording apparatus; $\Theta$ friction and toothed clutch for throwing out of gear the recording apparatus; N counter-shaft driven off shaft Z.

*Movement of paper band.*—$S^1$ cylinder carrying paper; $x_1$ roller drawing out paper and driven by the shaft T; $x_2$ pressure roller; $S_2$ cylinder upon which the paper is rolled; *s s s* small rollers guiding the paper; $T_a$ tracing table; $O_2$ pulley with friction clutch on spindle of cylinder S; △ batteries.

*Part of a Diagram of Trial made on August 28th, 1891.—Train 108, Neuchatel to Paris.*

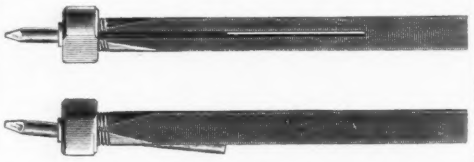
## BARBER'S SPLIT TOOL HOLDER.

The engraving below illustrates a form of tool holder which has been designed to suit all kinds of work, and to withstand the hard usage and knocking about which most tools receive in the machine shop. The holder is a split bar with a tapered screwed end carrying a taper nut, by which the two halves of the holder are pulled together, and the tool firmly held. There is no overhanging head, and consequently the slide rest can be brought close up to the cut; the tool will also cut either left or right hand, and will easily cut into corners of collars, &c. There are only two parts, a bar and a nut—nothing to get out of working condition. It will take the cut that can be made by the ordinary bar tool. Ordinary round steel is used for the tools. It is made in sizes to take $\frac{5}{16}$in. tool steel, and in large sizes, equal to the heaviest work and cut met with in an engineer's shop. Such holders must save a great deal of time on the part of turners and tool smiths, and they are not expensive. It is made by Mr. T. W. Barber, Queen Victoria-street, London.

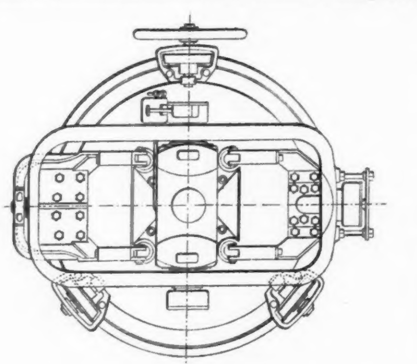


## TOWER'S STEADY PLATFORM.

This is an apparatus, manufactured by Messrs. Sir W. Armstrong, Mitchell, and Co., Newcastle-on-Tyne, for obtaining steadiness as regards angular motion on board ship, any object mounted on it being entirely exempted from pitching and rolling motion.

The steady platform is supported on gimbals so as to have within certain limits complete angular freedom. The rings and joints of the gimbals are made hollow so as to provide a passage for high-pressure water, which is pumped from a small steam pump to actuate the mechanism on the steady platform.

This mechanism consists of a heavy wheel revolving rapidly in a horizontal plane on a ball-and-socket bearing. This bearing is hollow, and through it the high-pressure water passes into the interior of the wheel, from whence it issues in three jets, two issuing from the periphery of the wheel in a tangential direction maintain the wheel's rotation by their reaction; the other issues upwards in the direction of the wheel's axis. This is called the axial jet, and two-thirds of all the water supplied to the machine passes through it, and by it the gyrostatic steadiness of the wheel is imparted to the platform as follows:—The wheel revolving on a ball-and-socket bearing, its plane of rotation has a small amount of angular freedom, but by a system of four small pendulums pressing by means of bell-crank arms on its rim it is caused to slowly become horizontal, and owing to its gyrostatic properties it remains so in spite of forces acting through short intervals of time tending to disturb it.



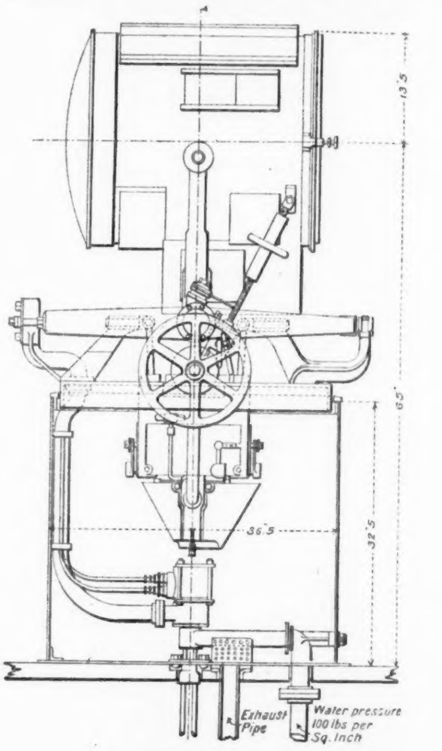
PLAN

The plane of the wheel being horizontal, the direction of the axial jet must in consequence be vertical, and it is the maintenance of this vertical jet which is the sole object of the wheel.

Immediately above the nozzle of the axial jet, and at a short distance from it, there are four open ports or holes close together in a horizontal metal face. Each of these ports is the open end of a passage communicating with a cylinder. These four cylinders are fixed at the corners of the platform, and push by means of rams or plungers against fixed points outside the platform, so that by the relative strength of their pushing they can cant the platform in its gimbals and control its plane relatively to the ship's deck.

The water pressure in these cylinders, and consequently the strength of their pushing, is regulated by the position of the centre of the axial jet in striking the four open ports. If the centre of the axial jet strikes exactly on the centre of the four ports, the water is equally divided between them, and a consequent equality of pressure exists in the passages and cylinders, but if the axial jet is the least out of centre to the ports, one port receives more and another less of the jet, and an inequality of pressure thus established causes some of the cylinders to press harder than others and cant the platform in such a way as to restore the concentricity of the axial jet and the four ports. Thus the gyroscopic wheel compels the platform to remain in a plane parallel to itself, and yet no force tending to disturb the platform can be communicated to the wheel. The water from the axial jet, after striking the ports, rebounds downwards and falls into the tank, which forms the base of the apparatus, from whence it returns through a pipe to the pump. When owing to the motion of the ship the plungers are moving in and out of the cylinders a portion of the axial jet water is being taken in by some of the cylinders and expelled from others; in order to establish this flow the ports communicating with the receiving cylinders have to be more covered by the axial jet than those communicating with the expelling cylinders. This would cause a small departure of the platform from the true horizontal, the error being in the direction of the ship's motion and of an amount proportioned to the velocity of its motion. This error is exactly compensated by the correcting cylinder, which is a small cylinder having a piston held in mid-stroke by a strong spring, the top of the piston-rod forming the point of attachment of the elevating screw. The two ends of the cylinder communicate by pipes with two narrow ports formed in the partitions between two pairs of the ports against which the axial jet plays. Any departure of the axial jet from concentricity covers more of one and less of the other of these narrow ports, and sets up a difference of pressure in them, which, acting on the piston in the correcting cylinder, displaces it by an amount depending on the strength of its spring, but which is adjusted so as to exactly compensate for the above-mentioned error.

This apparatus may in the future be used for many purposes for which steadiness at sea is desirable; such, for instance, as the mounting of telescopes, range finders, even smaller classes of quick-firing and machine guns, or other instruments, the use of which would be facilitated by a steady platform, but at present its use is confined to the mounting of search-light projectors, which are quite useless unless their ray can be kept directed horizontally. To illustrate this, suppose a vessel using a search-light takes five seconds to roll from port to starboard, and to be rolling through 10 deg., she will have a maximum angular velocity in the middle of the roll of 3 deg. per second. Supposing a torpedo boat to be approaching at a distance of two miles, the ray of the search light will at that distance be rising and falling at the rate of 630ft. per second, or 378 miles per hour. Supposing if by chance the ray crossed the point of the horizon where the torpedo boat happened to be at the moment, the small fraction of a second during which she would be revealed to the observer would be too short to be of any use, and the chance of seeing her again in any future rolls would be very remote; whereas, if the ray is kept always on the horizon, the observer has only to sweep it round to be sure of detecting a vessel approaching from any direction, and can then keep her constantly within the illuminating ray.



ELEVATION

The utility of vidette boats carrying search lights mounted in this manner for protecting an anchorage against torpedo boats is obvious; but such boats could not without steady platforms use search lights with any effect, owing to the liveliness of the motion in the least sea.

This apparatus has been found to keep a search light perfectly steady in a steam launch 50ft. long and 11ft. beam in the roughest sea.

## CATALOGUES.

The Farringdon Works, Limited, Shoe-lane, E.C. Pumping machinery, sanitary appliances, brass work, and copper goods. The catalogue contains several useful tables with an exhaustive index, is strongly bound, with name on back, and should be a valuable addition to the trade library.

Charles Burrell and Sons, Limited, Thetford. Agricultural engines, road locomotives and rollers, &c. A well illustrated catalogue of the firm's well-known agricultural appliances.

The Gardner Gun Company, London. Illustrative and descriptive of the various types of the Gardner machine guns.

The "Albion" Works, Sheffield. Catalogue of machinery in stock.

The Pneumatic Tire Company, Limited, Coventry. Pamphlet containing full particulars with regard to pneumatic tires for vehicles, with price list.

The Unbreakable Pulley and Mill Gearing Company, Limited. Price list.

Two heavy engines for fast passenger service are being built by the Schenectady Locomotive Works for the Boston and Albany R.R. They are intended to haul the Boston and Chicago limited express on the mountain division between Albany and Springfield, where the grades are sometimes as much as 85ft. to the mile. The cylinders are 19in. by 24in., and the driving-wheels 5ft. 9in. diameter.

## LETTERS TO THE EDITOR.

*We do not hold ourselves responsible for the opinions of our correspondents.)*

### THE THEORY OF THE STEAM ENGINE.

Sir,—Mr. Cherry, having first stated that my views were erroneous, and being pressed for elucidation of his own, gives up, contenting himself with restating that I am wrong. Now, if Mr. Cherry were a wholly obscure individual, this would matter very little; as it happens it may matter a good deal, for, unless I am led astray by a name, Mr. Cherry does something in the way of educating young men who would be engineers. Under the circumstances he has no right to perpetuate error. My contention is that certain things are daily taught concerning the steam engine which are not true. If they are true, Mr. Cherry, who defends them, can prove their truth. He is quite competent to the task. If they are not true, then he should hold his peace, and not endeavour to escape by saying that he has no time to deal with the subject. He should have thought of that before he wrote his first letter. This much premised, I take leave of Mr. Cherry and proceed to explain more precisely what it is that I want to prove.

In the first place no distinction is made in text books between different classes of heat engines; on the contrary, we are told that their efficiency is totally independent of the nature of the working substance, which may be gaseous, liquid, or solid; the amount of work which the material can do depending on the difference between an initial temperature T and a terminal temperature *t*. This proposition I assert to be untrue as regards steam, and any theory of the steam engine based upon it must be false and misleading.

Let us consider what a pound of steam represents. I condense the following figures from Isherwood's tables:—

| | | H Thermal units D ÷ 772 | D Dynamical Equivalent H × 772 | Per cent. of total heat. |
|---|---|---|---|---|
| | Total heat of steam of 212° from water at 32° .. .. .. .. .. | 1146·6 | 885,175·2 | 100·0 |
| Heat in water | Raising temperature from 32° to 212°, and lessening cohesion of water .. .. .. | 180·89 | 139,653·3 | 15·77 |
| | Increasing the volume of the water between 32° and 212°.. | 0·00187 | 1·44 | 0·0002 |
| Heat in steam | Destroying cohesion of the water, that is converting it into steam .. .. .. .. | 893·66 | 689,910 | 77·94 |
| | Increasing the volume of the water from that which had as water to that which it has as steam .. .. .. .. .. | 72·03 | 55,610 | 6·28 |
| | Total .. .. .. .. .. .. | 1146·6 | 885,175 | 100· |

The first mistake made in text books lies in calling the 893·66 units, given above, "latent heat." The heat expended in doing the work of steam making has been entirely lost as heat; it has been converted into work. It is true that the work can be got back again in the form of heat, but for the time being it has been lost.

It is necessary here to direct attention to a circumstance continually overlooked, which will serve to show how vague and indefinite are received ideas on the subject of latent heat. If we turn to a steam table and look up, let me suppose, steam of 100 lb. pressure absolute, we find that there was expended in producing 1 lb. of it 1181 units; that is to say, 1 lb. of water at 32 deg. has been all boiled away into steam of 100 lb. pressure. But according to the tables, the resulting pound contains only 883·38 units of heat. What has become of the difference? If we condense 1 lb. of steam to water at 32 deg., we shall get the whole of the work back, but we ought to get back only 883·38 units. The explanation of the seeming puzzle is, of course, that the heat which we apply is expended not only in making steam, but in raising the temperature of that steam. The temperature part represents unconverted heat, the "latent" units represent "converted heat," and the title "converted" is in every repect superior to "latent." It does not mislead.

Now it is a physical or natural law that steam of a given pressure must have a given temperature, so long as the steam is saturated. I have mentioned the fact that Rankine believed that steam allowed to expand without doing work would be superheated. I am not aware of any experiment being made to test the question, and it is worth while to quote Isherwood on this point. After quoting Joule's and Thomson's monumental experiments on the free expansion of gas, he says: "When the pressure on one side of the diaphragm was 4·7 atmospheres and on the other 7 atmospheres the interior work was $\frac{1}{858}$ the exterior work, in the case of hydrogen, $\frac{1}{174}$ in the case of air, and $\frac{1}{32}$ in the case of carbonic acid gas. Of the gases, hydrogen appears to approach nearer than any other to the state of a perfect gas; that is to say, it is at equal temperatures and pressures the furthest removed from liquefaction. Oxygen and nitrogen much less resemble a perfect gas; while carbonic acid gas is greatly different in mechanical characteristics. A just analogy therefore allows the presumption that steam, which liquefies by the slightest abstraction of heat, and has considerable cohesion, departs immeasurably from the state of a perfect gas, and, when freely expanding, undergoes much condensation, due to the transmutation of a portion of its heat into the internal work done upon its particles in overcoming their cohesion and forcing them further apart. Nor is this conclusion opposed to the fact that, as a given weight of steam of higher temperature possesses more heat than the same weight at a lower temperature, the change from one to the other by expansion must be accompanied by an evolution of the difference between these quantities; for the heat transmuted into internal work during the change is so great as not only to absorb the quantity evolved by it, but an additional quantity to be obtained only by the condensation of a portion of the steam." The fact that steam is superheated by wire-drawing does not controvert Isherwood, because, in the first place, the expansion is not free, much work being done in forcing the steam through a reduced orifice, and in the second it is generally admitted that the superheating is due to the friction of the particles against the metal.

Now let us see what happens when steam is admited to a cylinder, and for simplicity of statement I will assume that the initial pressure of the steam is 150 lb. absolute, that the cylinder is non-conducting, that the steam is dry saturated, that is to say, carries no free water, that the expansion is tenfold, and that there is no clearance. Any of your readers who understand the subject can correct my figures for an actual case.

The temperature of steam of 150 lb. is 305·5 deg. That of steam of 15 lb.—the terminal pressure of 150 lb. steam expanded ten times—is 213 deg. Then by the $\frac{T-t}{T}$ rule we have an efficiency of ·12, which means that of the whole heat in the steam 12 per cent. has been converted into work done on the piston.

Now let us proceed to see how far the statement agrees with facts.

Starting nominally from zero, we have in one pound of steam 1191 units, representing 919,452 foot-pounds. The pound of steam represents 3 cubic feet and a minute fraction, with which we need not concern ourselves. In the first place I will, for an obvious reason, deal with the steam as if it were a perfect gas, that is to say, there shall be no liquefaction caused by the performance of work. Starting with 3 cubic feet, we have at the end of the operation 30 cubic feet. Let us suppose that we have a piston 1 square foot in area traversing a cylinder 30ft. long. The average pressure will be $\frac{150 \times (1 + \text{hyp. log. } 2{\cdot}3)}{10} = 50\text{lb.}$, and $144 \times 50 \times 30 = 216{,}000$ foot-pounds; that is to say, 23 per cent. of the total heat expended in producing a pound of steam can be converted into work instead of 12 per cent. In this case I have treated the steam as a permanent gas, to bring it on all fours with air, and I have shown that its efficiency, dealing with heat as a quantity and not as a temperature, is nearly double that given by the $\frac{T-t}{T}$ rule.

But steam is not a permanent gas, and because it is not, the efficiency will not be so high as I have stated, because the average pressure will be less than 50 lb. "The pressure varies," says Rankine, "as the reciprocal of the tenth power of the ninth root of the space occupied," or as $p\,v^{\frac{10}{9}}$. But scientists are not agreed on this point. In the United States $p\,v^{\frac{17}{16}}$ seems to be preferred. Under the circumstances, I do not think it is necessary that I should take up further space by making the small alterations needed in my figures.

I have said enough to show that, confining our attention to the temperatures of the working fluid steam in the cylinder, we get results which are deplorably wrong. The true efficiency depends on the amount of heat expended measured in foot-pounds—in the case of the steam engine in making the working fluid and in raising its temperature—and on the quantity of work got back, also measured in foot-pounds. In the case of an air or other gas engine, no work is expended in making the fluid, but only in heating it. The two cases are quite dissimilar. It will be found that every writer on the subject of recent years, seeing that while $\frac{T-t}{T}$ may be made to do for cylinder temperatures in an air engine, it cannot be made to do at all for a steam engine, has altered the base, and takes furnace temperatures at one end and condenser temperatures at the other, a method quite as misleading as that which I have criticised. In short, the efficiency of a heat engine is not independent of the nature of the working substance.

I shall perhaps be told that I ought to take the condenser temperature for *t* instead of the temperature at the point of release; but the moment the steam leaves the cylinder we are done with it, and it can no longer do useful duty.

I have heard it argued that $\frac{T-t}{T}$; the thermodynamic function, and so on, only refer to a complete special cycle. Quite so. That is my contention. The head and front of my argument is that in practice the efficiency of a heat engine is not independent of the nature of the working substance, and that text-books of the steam engine are, with a few exceptions, quite misleading on the point. In fact, theoretical thermodynamics are not only useless but mischievous, as far as the steam engine is concerned.

October 1st. Maurice Cross.

Sir,—I have read with interest the letter of your correspondent, Maurice Cross, in your issue of 22nd September, on the above subject. He takes exception to the use of the formula $\frac{T-t}{T}$ as a standard of efficiency for steam engines, and from the way in which he has attempted to make good his theory, it is clear that he has slipped into the common mistake of applying a result deduced under certain assumed conditions to a case in which these limiting conditions do not obtain. The conditions on which the formula in question is based are that the working fluid must pass through a complete cycle of operations, and that this cycle must be a reversible one. It is obvious then that any argument built on the application of this formula to a portion of a cycle is both worthless and misleading. Any one familiar with the cycle of operations in actual steam engines knows that it is not a reversible one, and therefore the formula in question is inapplicable. For a description of the ideal case of a reversible steam engine cycle, your correspondent may refer to Professor Cotteril's work on the steam engine, Art. 83. There he will find a comparison of the actual steam engine cycle with the ideal or reversible one.

It is well to remember, however, that although this formula is not applicable to the actual steam engine as a standard of perfection, it is nevertheless important, from a thermodynamic standpoint, to have a common standard of efficiency for gauging the efficiencies of all heat engines. If the steam engine does not conform to the conditions of maximum efficiency, so much the worse for the steam engine. Whether the formula $\frac{T-t}{T}$ can be rationally considered as a standard of perfection for any heat engine is, to say the least of it, doubtful, implying as it does that heat can be got into and out of the working fluid without expenditure of energy, an assumption as untenable as the possibility of perpetual motion. James D. Mackinnon.

Glasgow, October 1st.

### GOVERNING ELECTRIC LIGHT ENGINES.

Sir,—Your article upon this subject is valuable and interesting, but it may be doubted whether the subject is so much in need of the "competent inventor" as is assumed. It is right to say that "the thing will never be done if a cotton mill engine is taken as a standard," but there are high-speed engine makers who have given as much attention to the subject of governing as cotton mill engineers, and, as they believe, with as much success; it is only necessary to refer to the late Mr. Willans. You, apparently, intending to take a typical electric light engine, select one running at 100 revolutions per minute. Your argument is of course unaffected by the number of revolutions, but does not the selection suggest a turning of the eyes towards the cotton mill engine after all, in forgetfulness of the fact—about which I believe there can be no doubt—that of all the public electric lighting work in Great Britain, very much more than half is performed by high-speed engines running at from 350 to 400 revolutions per minute, and standing on a much better footing as regards governing than an engine designed to run at 100 revolutions only? Surely it would not be unreasonable to take an engine of the high-speed class as the typical electric light engine. The first point I would refer to in your article is the very useful demonstration of the inevitableness of some change of speed with a change of load, owing to the different position necessarily assumed by the governor balls. It were well if this fact were generally understood; there would be less asking for impossibilities. It is, however, easy to give an accuracy of governing quite sufficient for the purposes of an electric lighting station; a total variation of 2 per cent. between full load and a very light load—which means a variation of speed of less than 1 per cent. through any variation of load likely to occur in practice—is easy of attainment. The change from 150-horse power to 300-horse power, which you consider, need not involve a greater change of speed than this, and certainly, if in any station the engines are run with a much greater variation of load than from full load to half load, there must be something so radically wrong, either in the design or in the management of the station, that all governing questions sink into insignificance beside it. The continental blunder of using a very few large units of power, instead of a greater number of small units, is happily understood, and is generally avoided in this country.

Having in view important stations where direct-coupled alternators of large power are driven at high speeds by Willans engines, and where the working is reported to be absolutely satisfactory, one is tempted to wonder what class of plant it is which gives rise to the complaints of electrical engineers which you refer to. If closer governing than is above described is required by any electrical engineer—though it is hard to understand why—the means for attaining it are quite well understood. It is only necessary to fit a Knowles supplementary governor to bring the main governor balls always back to the original position. There are places where this is worth doing, but surely electric light stations are not amongst them.

Of equal interest are your remarks upon sudden changes of load, and the avoidance of "blinking" in connection with them. You advise a governor which on a small change of speed shall absolutely close the stop valve or open it wide. Now this is what any really well-designed governor, such as that originally schemed by Mr. Willans, does; except that, for the avoidance of hunting, it never absolutely closes, but always leaves an opening sufficient for the passage of steam enough to run the engine light. The throttle valve is of such proportions that a very small travel covers its whole range from closed to open, and is produced by a correspondingly small movement of the governor balls. Your picture of the desired effect—"a series of very rapid alterations or oscillations"—suggests rather what one tries to avoid, though it is very likely to ensue if the change from full open to closed, or nearly closed, is produced by too small a movement of the governor balls. In other words, if the apparatus is too sensitive it will also be too delicate; it will move too easily, and the governor will hunt upon small provocation. To avoid this we must govern a little more coarsely, and substitute, say, 2 per cent. for 1 per cent. Nevertheless, it is comparatively easy to work to the 1 per cent. standard so long as disturbing causes, like variation of boiler pressure, grit in the valve, &c., are absent. But what should be pointed out is, that when we have thus been given exactly what in your article is asked for, we shall be no nearer to the desideratum—viz., the power to instantly increase the load from 150-horse power to 300-horse power without causing the lights to blink, and possibly to drop in intensity. No quickening of the governor action will help, for it already acts so quickly that in a slow-running engine the throttle valve may be shifted long before the next cylinder admission comes round.

The truth is that the interesting point you have raised is not a governor question at all; it relates solely and only to the fly-wheel. With such an increase of load as you suppose, no augmentation of the next supply of steam to the first cylinder, in a compound or triple engine, can produce power enough at once to prevent a check to speed. That can only be avoided by storage of power. For the moment the full power cannot be obtained from the engine, it must be obtained from a heavy fly-wheel, and there is no other way of preventing the drop in intensity of the lights. Needless to say, the whole matter is merely one of calculation when the data are given. The smaller the permissible drop in speed, for a given change of load, effected with a given quickness, the heavier the fly-wheel must be. As a fact, there never ought to be a serious "blink" in the lights, because there never ought to be a change both great enough and sudden enough to cause one. An instantaneous addition of 150-horse power to the load is scarcely conceivable in any lighting station, or if conceivable, it implies a plant of great size, giving an output compared with which 150-horse power is small. Let it be borne in mind that the supposed difficulty hangs upon the word "instantaneous;" if the change is spread over a few seconds even, the difficulty vanishes. An hotel or other large building may be brought on very rapidly, but scarcely instantaneously.

Engineers should recognise that in a great number of cases where they speak of good or bad governing, they really mean sufficient or insufficient fly-wheel power for the particular work in view, and nothing else. Mark Robinson.

Thames Ditton, October 2nd.

Sir,—I can fully endorse what you have said in your leader on this subject last week. To hope that we shall get what we want from the makers is waste of time. Engine builders neither understand our wants nor see their way to supply them. A favourite way out of all difficulties lies in suggesting the addition of a subsidiary governor, such as Knowles', or "The Cat." Very good in their way, no doubt, but much too slow. To me it seems that the best arrangement would be a clock governor; that is to say, there are two shafts revolving; one is kept to time by a clock or its equivalent, the other is the crank-shaft. So long as these revolve at the same pace the throttle valve is suspended. Any change opens or closes it by means of very simple well-understood mechanism.

About twenty-five years ago Mr. Bailey, of Manchester, made a governor very much of this type. I wonder if it is ever heard of now?

If steam engine makers only knew what we have to contend against, they would have supplied what is wanted long ago, perhaps.

It seems, however, scarcely worth while to spend much money in perfecting electric light governors, because the demand for them must be limited. Electrical Engineer.

October 3rd.

### LABOUR AND LUXURIES.

Sir,—The letter of "Y. X." in your last issue, with reference to some remarks made by a Woolwich workman, call, I think, for comment. The man's protest against being discharged when his services were no longer required was, of course, an absurd one, but hardly more absurd, I imagine, than your correspondent's threadbare fallacy that the expenditure of the wealthy on luxuries is necessarily beneficial to those who have to produce them.

The workman's objection to being stopped was on the ground that the wages paid to him per week only amounted to the cost of a bouquet worn by a Government clerk, whereon your correspondent goes on to explain a principle that "has always been held sound by the best authorities," namely, that the wearer of expensive bouquets is a benefactor to the whole army—which he cites—of bricklayers, carpenters, glaziers, gardeners, flower girls, &c., because he compels these people to work and provide him with luxuries, in order to win from him the money which—assuming for the sake of argument, he is of the independent classes—he himself has done no work to earn. This, though a most prevalent view of the case, is surely the fallacy.

For the sake of our argument, let us assume a more extreme case, namely, that of a millionaire who has got his money by cornering pork, wheat, or cotton, and who gives a smart function at his West End house, in which in the course of an evening flowers are consumed to the extent of £1500. Let this sum be taken as representing the labour of thirty men—in the shape of the aforesaid bricklayers, carpenters, glaziers, &c.—for one year at 20s. per week. Then what really happens is that these thirty men have to do a year's work in order to get back from your millionaire the £1500 which he took out of the pockets of the public when he cornered his pork and raised the price on them, and to obtain which he not only did nothing in return towards assisting in the production of the commodities of which he is a general consumer, but actually taxed the public.

But for the unsolicited and undesired attention of this gentleman in the interest of pork, the flowers in question might certainly not have been produced; but, on the other hand, the public would have been able to buy the same quantity of pork and still have the £1500 to expend on other labour for their own additional benefit, instead of having to produce flowers for a man who had exploited them.

There is no escaping from the fact that since commodities, be they flowers, carriages, dress, or what not, are only produced by labour, those who consume them without assisting in the production—directly or indirectly—do so entirely at the expense in labour of those who produce them; and, in proportion as our social system permits of wealth being accumulated without equivalent labour, in precisely the same proportion is the labour of the working classes increased beyond what is requisite to produce the commodities they themselves consume, the balance between what they consume and what they produce going to the idle; this being the reason why idleness and luxury are invariably found side by side with poverty and overwork.

I am far from wishing to imply that honourably won leisure is to be deprecated; but, on the other hand, let us be honest enough to see and admit that no benefit is conferred by the wealthy being in a position to command commodities which existing social conditions force the working classes to produce for them. R. G. B.

Macclesfield, October 2nd.

## RUSTLESS COATINGS FOR IRON AND STEEL.*

By M. P. Wood, New York City, Member of the Society.

(*Continued from page* 264.)

Sir Wm. Thompson's paper, read at a recent meeting of the Manchester Association of Engineers, states "That he had found red lead the best preservative coating for structural iron and steel from rust. This result," he says, "is remarkable, as red lead is a highly oxidising substance; but the reason is found that the red lead had the effect of producing a skin of black or magnetic oxide on the iron itself under the paint." Manganese dioxide, a strong oxidising substance, also forms an excellent paint for metallic surfaces, principally from the same cause that Sir Wm. Thompson gives for red lead. Cast iron generally seems to withstand corrosion from exposure to the atmosphere, sea water, acidulated water, sulphuric and chemical fumes better than either wrought iron or steel. Trautwine's citation of the cannons immersed in the sea for 62 and 133 years, and being as soft as plumbago when taken out, can be supplemented with the fact that they were nearly of the original size, while the anchors and chain cables removed at the same time were corroded away to but skeletons, and had hardly more strength per inch of metal than the cannons. It may be noted that when the cannon and anchors were first taken out of the sea, they absorbed oxygen from the atmosphere at so rapid a rate as to become so hot that they could not be handled, a condition noticeable for a number of days. As between a gray cast iron recommended by Mr. Turner, Assoc. R.S.M., F.I.C., for iron constructions immersed in the sea; and Mr. Trautwine, who recommends white close-grained cast iron, I should prefer to follow Mr. Trautwine, but it is a question of guessing which to select. Parts that need machining will require to be softer than those that can be put in place as they come from the foundry. Accurate data is wanting on all these points. Experience is a dear school, and a slow one in its deductions. It has been noted that cast iron car wheels immersed in both fresh and sea water for many years, show less corrosion on the chill part of the wheel than on the body. The iron is necessarily the same in both points, but the molecular arrangement of the iron due to the chill, not only imparts a higher resisting power to wear, but also to corrosion. This example shows that both Trautwine and Turner are right, though diametrically opposed to each other primarily and the governing effect of a condition rather than a theory.

Professor V. B. Lewis, of the Royal Naval College, Greenwich, England, at a recent meeting of the Institute of Naval Architects, London, states:—"The rusting of iron and steel is a definite chemical process due to the conjoint action of air, moisture, and carbon dioxide upon the metal. The increased rate of chemical corrosive action due to a local increase of temperature is noticeable, and may be due to galvanic action set up between portions of the same metal at different temperatures. It is an undoubted fact that the double bottom of ship plates near the boilers corrode more rapidly than similar plates in other parts of the vessel, and the increase in temperature near the boiler is the only factor. It is also noteworthy that the plates at the bottom of the cellular spaces, which are kept cool by contact with the sea water, do not corrode; and cases are noted in which parts of a plate, which get locally warmer than other parts—although the difference can only be a few degrees—corrode much more rapidly than the cooler portions. Experiments show that the rapid corrosion found in the double bottoms near the boilers or other sources of heat is due to galvanic action, and not to the increased chemical activity due simply to the increase of temperature. As the ashes are drawn and quenched with sea water near these exposed plates, no doubt some of the corrosion can be traced to the gases thus formed; the sulphur in the ashes also contributing its effect."

Graphite, mixed with pure boiled linseed oil in which a small percentage of litharge, red lead, manganese, or other metallic salt has been added at the time of boiling to aid in the oxidation of the oil, forms a most effective paint for metallic surfaces, as well as for wood and fibrous substances. Wood surfaces protected by this paint, and exposed to the action of sea water for a number of years, are found in a perfect state of preservation. Some recent experiments with this paint applied to the surface of boiler flues show that it prevents the formation of scale to a wonderful degree, and though it would seem in this case to also prevent the transmission of the heat to the water, yet it appears to be a better conductor than the scale which it prevents from forming. Steel tubes in locomotive and other high-pressure steam boilers pit more readily than iron tubes under the same conditions of service, so much so that on many railways the use of steel tubes is prohibited. If the experiments now in progress with this paint applied to locomotive boiler tubes are as successful to prevent corrosion and the formation of scale as in the case of the boiler flues, its use will add materially to the economies of railway locomotive service, and can hardly be less effective in many cases on marine boilers.

In many places in the south-western section of our country the water is so bad in scale-producing qualities as to require the removal of the boiler tubes after only two weeks of service, or a little over a 2000 miles run. Innumerable compounds of the anti-incrustation order have been tried and found useless to correct or even mitigate the trouble. If the simple application of a coat of plumbago paint furnishes a remedy for this evil, no better example of the "unexpected happenings" in favour of the engineer can be had. Engineers requiring a ready rule to determine the amount of paint required to cover any structure may find the following, from my own experience, to be of use:—Divide the number of square feet of surface by 200, the result will be the number of gallons of liquid paint required for two coats. Or, divide the square feet by 18, and the result is the number of pounds of pure white lead required to give three coats.

Another method or process for the protection of iron and steel has been recently invented by an Austrian, and is in practical use in Vienna. The United States patent No. 453,355 was issued June 2nd, 1891, and is described in the *Official Gazette*, vol. 55, page 1199. It is called the Haswell electro-browning or electro-enamel process, and consists of protecting the surface of iron and steel by a deposit mainly of peroxide of lead, prepared by the electrosis of a suitable lead salt in cold water. The deposit is produced and completed in twenty minutes, and does not require more than one treatment. Several samples of it are presented for the examination of the members. It appears to be best adapted to articles like shelf goods, hinges, and other cast iron articles of general hardware, also axes, edge tools, scythes, &c., that require protection from changes of temperature that cause sweating, also from the effects of handling and storage in damp places. The coating, while possessing considerable resisting power to the moisture, carbonic acid, and ammonia, that is in the air in its normal state; also, to diluted mineral and organic acids, and the chemical and other fumes of the workshop, is, not, however, of so high resisting power as to withstand immersion in either water, sea water, or acidulated mixtures beyond forty-eight hours, which under these conditions appears to be about the limit of its protective qualities. It can be polished on ordinary buffing wheels after it is applied, as shown by the round samples, it being unnecessary to polish the article before browning it, its colour then being decidedly pleasing, while the coating on the rough ground surface of the sample is far from objectionable. The sheet iron sample shows its effect upon iron as it left the rolls, a pickling to remove the scale being the only preparation required. The sheet iron can be bent to a right angle over a moderately sharp corner without cracking the coating or injury to its protective power. The coating has no chemical affinity with the metal which it is to protect. Whether dry or moistened it creates no changes on the surface of the article coated, and is not affected by mechanical injury like a blow, so as to flake off, expose the surface, and cause a rust spot to form. It stands hard rubbing with pumice stone wet or dry on a piece of felt, is not affected by the usual changes of temperature of the atmosphere, and bears a temperature of 350 deg. Fah., without injury. The cost of material in the electro bath is ten cents for 100 square feet of surface coated. The apparatus required consists of a few tanks to hold the lead solution, a few reels or racks to support the articles according to what they are; the whole at a cost of from 25 dols. to 250 dols. An ordinary electro-plating dynamo is required, the size depending upon the amount of work to be done, and power to drive the dynamo, &c., from $1\frac{1}{2}$ to 2 voltage is all that is necessary. Water must be provided, and drying facilities by steam oven or otherwise as is most convenient. The articles must be cleansed from oil or finger marks before immersion in the bath, but a limited amount of skilled labour is required in the process. The royalty for the use of the patent is not included in the above statement of cost. The technical value of the invention as to cost of application and its effectiveness, appears to rank next to the nitre process of Lieutenant-Colonel Buffington heretofore described; but for all purposes requiring the preservation of the finish and cutting qualities of highly tempered edged tools it has no competitor. The coating is easily removed by friction with turpentine, concentrated lye or benzine. Its application to finished shafting and kindred articles is feasible and practical, but on pulleys, machine tools, engines, and like bulky articles, the old white lead and tallow pot will hold its own for yet awhile, and the machine shop apprentice will not be deprived of a chance to develope his artistic proclivities. There are a few compounds for the temporary protection, rather than the preservation of machined or bright surfaces, of iron and steel that, not an enduring as paint, may be denominated lotions; some of them are effective and easily applied. Krupp uses a compound called Mannocitin for his bright steel, machined articles, and ordnance in store. It does not turn rancid or harden with age, is consistent enough to resist torrid temperatures without slumping off, is easily removed by turpentine or benzine, and is a valuable substitute for the old tallow pot product. Coal-tar, a product from the distillation of gas coal, when properly prepared forms an effective protection from corrosion of iron and steel from ordinary atmospheric attack, and if reduced to a pitch compound and applied to the metal in form of a hot bath, in which the article is immersed for a sufficient time to allow it to attain the same temperature as the bath, the coating formed is but slightly inferior to red oxide of lead paint, and in some applications is much cheaper. In all cases the removal of the scale of the rolls or foundry sand produces superior results. The coating formed has about the same elasticity as the metal, and withstands mechanical injury very well. The composition of the tar has much to do with the success of the application. Coal-tar from gas coal and cannel coal, as it is collected from the hydraulic main, by analysis consists of the following elements as averaged from a large number of samples. A 40 gallon barrel consisting of:—$1\frac{1}{2}$ gallons, or 3 75 per cent. of light oils, consisting of benzole, naphtha and carbolic acid. $9\frac{1}{2}$ gallons, or 23·75 per cent. of heavy oil, consisting of creosote oil and anthracine; 29 gallons, or 72·5 per cent. pitch. Boiled in open kettles, this should be reduced from 15 per cent. to 25 per cent., according to the duty required of it. The tar resulting from the distillation of petroleum oils for gas is of a decidedly inferior quality to that obtained from gas coals, and is better adapted for coating the cruder forms of wood constructions, piles, dock timbers, fence posts in the ground apart, than metal work. But this same oil tar, if distilled at heats from 600 deg. to 800 deg. Fah., forms a pitch of almost adamantine hardness when cold, and resists almost all corrosive agents, except those of the hydrocarbon class. When the concentration of the gas coal-tar is carried to the 25 per cent. or 30 per cent. stage, the product is comparatively ordourless, or at least is not any more objectionable than that from oil paint, the pungency due to the light oils and carbolic acid being dissipated.

Galvanising or coating metals with zinc, and its alloys of tin, antimony, arsenic, lead, &c., is a well-known process, and its value is well recognised, as the extensive application of it for a large variety of purposes shows, but it is easily attacked by weak acidulated liquids, sulphurous and other atmospheric fumes, and the protection afforded, except in fairly protected and favourable locations, is but temporary. Its mission is so short lived, and corrosion once commenced proceeds so rapidly in unlooked-for spots, that one is forced to recognise the potency of the remark, "and the end of that process was worse than its first condition." The Ajax patent coating, so extensively advertised a few years ago, was a coating of lead and its alloys applied to iron surfaces which had undergone a peculiar pickling and cleaning process to free them from scale, sand, &c. Other than this point it had no merit over the ordinary galvanising process. Zinc and tin, with the other before-named metals, are by themselves all electro-positive to iron and steel, but when alloyed or combined with each other are more potent to introduce electrosis action upon the baser metal and hasten decay. The covering of church spires and court house cupolas with bright tin used to be a familiar method of marking the importance of the structure to the rustic communities. These were undimmed by paint, and in many cases were uncorroded and bright after fifty years or more of exposure, but the covering was pure tin plate and honest work, and when leaks did occur in the covering, it was always in the seams where the solder had introduced some lead alloy to begin its incipient work of decay. When the tinning fraternity began the use of acid in connection with resin—and in many cases used acid alone—as a flux to the solder, the life of the roofing was materially shortened, the job hastened to completion, but the tinker never took a cent off the bill.

The advent of coal as a domestic fuel instead of wood, as well as the fumes of coal smoke from multiplying manufacturing establishments, soon produced an effect upon the bright tin roofs, and paint of varying qualities, and in too many cases of a cheap John order, as being good enough for a house roof, became the order of the day to preserve the work. At present the fierce competition for orders between our Free Trade brothers across the sea, as well as the unscrupulous character of some of the Budensiek contractors and builders—and in many cases the engineering craft are guilty of acquiescing in and calling for cheaper materials—has brought into the market a quality of tin and terne plates that have about reached the maximum point of cheapness and nastiness as a vehicle to hold paint on a metallic surface. As an engineer remarked when questioned as to the quality and merits of a special brand of tin roofing plate, imported for a specially fine job, "Oh, yes, we had it painted when it was boxed and shipped, it was painted again when we received it and took it out of the box, painted again when it was ready to lay in place, and after laid had two coats given it, and the business lasted about six years, when we ripped the thing off in midwinter and laid a tarred felt, coal tar and gravel roof, which has been down twelve years, and is sound and tight as when laid, and did not cost one-half as much as the blessed tin did, including the expense of taking the thing off." The failure was due wholly to corrosion from the inside outward. Certainly all of the plates, nearly a thousand in number, could not all have been improperly pickled, scaled and cleansed before coating; but they did receive from the tin bath a uniform application of a tin and lead or other alloy coating, that pitted in a dozen places almost every plate laid on the roof. I hardly think it advisable for any one to approach that engineer for an order for tin roofing plates even if backed by a strong guarantee.

The alloy of zinc, lead, antimony, arsenic, &c., with the tin used in the cans and vessels in which so large a quantity of our daily food is now marketed, is a serious menace to the public health. The most casual inspection of "the dump" that graces all our cities, towns, villages, hamlets, and even the solitary cottage beside the sea or 'neath the sheltering hill, can but convince one of the dangers we are daily exposed to from the cumulative poisons taken into our systems from this cause, and though we as a nation are wont to demur to the too close inspection of and interference in our so-called private affairs, matters are so fast assuming a crisis stage from our greed for the almighty dollar, with the sentiment as a ruling passion: "No matter what happens so it does not happen to me," that relief and reform must be had, even if national, state, city, and town inspectors and Boards of Health one and all are called into being; happily if they could be divested of all political character, for the purpose of curtailing and controlling this growing cause of disease and death. The terror that lurks in the deadly tomato can is fast losing its joke and becoming a sober reality. The benefits that arise from a careful inspection of the metal wares enclosing food products, even if the proceeding may partake too much of the paternal government character, is strikingly shown by the examination of the French articles so prepared, and a comparison of that tin ware with the best samples of English, German, and other continental countries, and noting its superior qualities, and how remarkably they resist corrosion or change from any of the vegetable acids in food or to that due to fermentation. Our American tin-plate manufacturers have much to learn in this matter, and may study French methods of manufacture with better results than those the imported Welshmen are trying to introduce.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(***From our own Correspondent.***)

Business on the Birmingham Iron Exchange this week has been a good deal contracted, owing to the near approach of the quarterly meetings next week. Nevertheless the improvement in the tone of trade exhibited no signs of lessening, and ironmasters take an encouraging view of the future. It is generally held that the past three months will compare satisfactorily with either of the third quarters of 1893 and 1892 as regards the quantity of work given out. The continued intelligence from the United States of trade revival is occasioning much satisfaction locally, and is tending to strengthen these exchanges.

It is considered improbable that the official minimum of marked bars, viz, £7 10s. to £8 2s. 6d., will be altered next week, as it is reported within the last few days that contracts for branded iron have been entered into up to the end of the year at present rates. Second-branded bars are quoted £6 10s., but some makers have endeavoured to obtain 2s. 6d. per ton beyond this figure to compensate them, they state, for the higher prices which have to be paid for crude metal, but in very few cases has it been allowed. Common bars are firm at £5 10s. Galvanised sheets remain at £9 15s. to £10. Plain sheets, doubles, are firmer at £6 12s. 6d. to £6 15s., and lattens, £7 5s. to £7 7s. 6d.

The firmness in pig iron is upheld by the iron and steel bridge work orders, amounting, it is rumoured, to some 20,000 tons, which have been placed with local firms for the new Sheffield-London railway. It is understood that other considerable bridge work contracts for the same scheme have been secured by Messrs. Handyside and Co., Derby. The names of two large Staffordshire constructive engineering concerns are mentioned in connection with the Staffordshire orders already received, and the probability is that additional local firms will be favoured later on. Staffordshire pig iron is quoted 55s. to 57s. 6d. for all-mine hot air qualities, part mines 42s., and cinder 38s. Northamptons are this week 41s. 6d. to 42s. 6d., Derbyshire 42s. 6d., and Lincolns 43s.

The accountants to the Midland Iron and Steel Wages Board have declared the net average selling price of iron for the months of July and August to be £5 18s. 5·46d. per ton. This, as compared with the price of the two previous months—May and June—is a decline of 11d. per ton, the average at the end of those months being £5 19s. 4·98d. Contrasted with the corresponding months of 1893, the present declaration is a drop of 1s. per ton, the value decreed for July and August last year being £5 19s. 5·67d. Notwithstanding the fall, puddlers' wages are to remain unaltered, the operatives continuing to receive 7s. 6d. per ton, and millmen in proportion.

A claim for superiority of iron over steel for special engineering purposes was made by Mr. Thomas Ashton, of the Netherton Ironworks, Dudley, in his presidential address to the Staffordshire Institute of Iron and Steel Works' Managers a few days ago. Mr. Ashton believed that, notwithstanding the advance of steel, there would permanently exist a good demand for weldable fibrous iron for special engineering purposes. This, he held, would be preferable to a rigid homogeneous ingot iron, notwithstanding the assertions of steel makers to the contrary. A more uniform and satisfactory metal could be obtained by the puddling process where a ductile, weldable material was essential. Mr. Ashton claimed that the results of experiments proved that the ultimate strength of steel was less than that of iron. For this reason a marked reaction has of late taken place in favour of high-class iron for special engineering and locomotive work. The President of the Institute stated that a case had recently come to his knowledge where a railway company, after a lengthened and thorough trial of steel gearing and couplings, finding that they were not to be relied upon, refitted the whole of their rolling stock with others made of iron. Mr. Ashton's views have been challenged by Mr. R. Smith Casson, late of the Earl of Dudley's Iron and Steel Works, one of the best authorities on steel making in this district, who especially takes exception to the statement that steel will not weld.

The strike of miners in the Romley district continues, and to all appearances bids fair to do so for some time. About three weeks ago wages were reduced 10 per cent., in accordance with the general reduction arranged by the Staffordshire Wages Board. The operatives objected to the full reduction, declaring that they had voluntarily suffered a diminution at the Rowley Station Colliery, varying from 1d. to 3d. per day, about two years ago, and that this should be taken into account. The proprietors of the mine appear willing to restore the 3d. per day reduction referred to if the miners submit to the Wages Board reduction, but at present matters are at a deadlock.

## NOTES FROM LANCASHIRE.

(***From our own Correspondents.***)

*Manchester.*—Except that makers and manufacturers have their books better filled, and are therefore not at all anxious sellers, the position in the iron trade of this district so far as actual business doing is concerned, is getting back to very much what it was a couple of months ago. There is little or no inquiry of any weight stirring in the market, and although there is no pressure to sell, prices have scarcely the firmness they had a week or two back, a tendency to give way slightly being already noticeable in some cases. The engineering industries still show no sign of real improvement. So far as there is any change, it is perhaps for the better, but not to any sufficient extent to make itself actually felt. Engineers, however, talk more hopefully, and there seems to be an undercurrent of feeling, which although it has at present no very substantial basis, gives a more encouraging tone as regards the future.

The Manchester Iron Exchange on Tuesday brought together about an average attendance, but only a very slow market was reported generally. Users of pig iron are just now buyers of only very small quantities, and the demand is chiefly upon foundry qualities, forge numbers not only meeting with little or no inquiry, but in some cases consumers are scarcely taking the deliveries of iron they have already bought. Lancashire makers are still quoting on the basis of 40s. for forge to 42s. for foundry, less 2½ at the works, or equal to 42s. 6d. for forge and 44s. 6d. for foundry, delivered Manchester; but they are only booking occasional small parcels—chiefly of foundry—at these figures. With regard to district brands, foundry descriptions are fully maintaining late rates, Lincolnshire not being quoted under 41s., with Derbyshire remaining at about 45s. 6d. to 46s. net cash, delivered Manchester; but forge qualities are in some cases becoming rather more plentiful in the hands of makers, and a disposition is being shown to give way slightly upon recent quotations, forge Lincolnshire scarcely now averaging more than 39s. to 39s. 6d. net cash delivered Manchester. Outside brands offering in this market have not been appreciably affected by the slight giving way in warrants during the week, which has probably in some measure been due to the evident collapse of the Scotch miners' strike. Ordinary foundry brands of Middlesbrough might be bought readily at about 44s. 10d., but for special brands makers are still firm in quoting 45s. 4d. net cash delivered Manchester. As sellers of Scotch iron have only very limited quantities to offer, and the supplies coming into the market are not likely to be at all appreciably affected for some weeks to come, buyers who require prompt delivery have still to pay special rates, Eglinton being scarcely obtainable under 49s. 6d., and Glengarnock 51s. net prompt cash delivered at the Lancashire ports.

In the finished iron trade the position is still without improvement, forges only in exceptional cases working more than four days per week, and manufacturers report no increased weight of business coming forward. Quoted prices remain unchanged, Lancashire and North Staffordshire bars averaging £5 7s. 6d. to £5 10s., Lancashire and Staffordshire sheets £7 to £7 5s., and Lancashire hoops £5 17s. 6d for random, to £6 2s. 6d. for special cut lengths, delivered Manchester or Liverpool.

In the steel trade there is only a quiet sort of business doing, with good foundry hematites quoted at 53s. to 53s. 6d., less 2½, and ordinary Bessemer basic billets about £4 net cash delivered Manchester. With regard to manufactured steel, makers of boiler-plates are still quoting £6 7s. 6d., but there are sellers at £6 5s., with Scotch makers quoting for delivery when works restart at £6 5s. per ton, delivered in this district, and this figure seems to represent the top price that is obtainable from consumers here.

In the metal market the recent further advance in list rates for manufactured goods still operates as a complete check upon business beyond the merest hand-to-mouth requirements, consumers evidently anticipating that prices will have to get back to previous rates, as raw material is showing a downward tendency.

The various works in connection with the Manchester Ship Canal are making satisfactory progress, and the same may be said with regard to the steadily increasing traffic along the waterway. The new three-storey sheds at the Manchester and Salford Docks, of which a full description has already been given in the columns of The Engineer, are being rapidly pushed forward, and will very soon be completed. At the Eastham end some modification is being made with regard to the scheme for constructing a guiding jetty outside the locks, and in the place of this jetty, a series of dolphins extending 1800ft. on the river side, and about 400ft. on the opposite side, are being constructed to provide additional facilities for guiding ships entering the canal, and preventing any possibility of tide-wash dragging them out of the way. The contract has been placed in the hands of Messrs. Topham, Jones, and Railton, of London, and should the dolphins, when completed, be found insufficient, the original intention of erecting a jetty can be readily carried out by constructing this between the dolphins which are now being put down.

The only improvement that can be reported in the coal trade is a slightly increased demand for the better qualities suitable for house-fire purposes, which is only to be expected with the approach of the usual winter requirements. For other descriptions of fuel there is a continued only very slow demand, and it is exceptional where pits are working more than four days per week. Common round coals are in very indifferent request for iron-making, steam and general manufacturing purposes, and engine classes of fuel continue more or less a drug in the market, with excessively low figures taken in some instances to effect clearance sales. At the pit mouth prices for the better qualities of round coal are steady at about 11s. to 11s. 6d. for the best qualities, 10s. to 10s. 6d. for seconds, and 8s. for common sorts, but it is only in exceptional cases that more than these figures is being got. Ordinary descriptions of steam and forge coal can be readily obtained at 7s., with some of the better qualities quoted at 7s. 6d., and engine fuel ranges from about 3s. 6d. and 4s. for the very common sorts, to 4s. 6d. and 5s. for medium qualities, up to 5s. 6d. and 6s. for the very best descriptions.

In the shipping trade a fair weight of business is being done for Ireland, but there is a falling-off in the demand for Scotland, and prices are perhaps not quite so strong as they were, common round coal delivered at the ports on the Mersey scarcely averaging more than 8s. 6d. to 9s. per ton, according to quality.

For some time past negotiations have been going on between the official representatives of the Lancashire and Cheshire Coalowners' and Miners' Federations, with the object of forming a Conciliation Board for the settlement of local disputes which would not in the ordinary course come before the general Coal Trade Conciliation Board; but at a joint meeting of coalowners' and miners' representatives held in Manchester on Wednesday to consider these proposals, the Chairman of the Coalowners' Association, Mr. Alfred Hewlett, intimated that at a previous meeting they had passed a resolution to the effect that inasmuch as under the provisions of the Lancashire and Cheshire Coalowners' Defence Association there already existed a machinery for the settlement of local disputes, it was undesirable for the present to proceed further with the establishment of a local Conciliation Board. The miners' representatives have of course to accept this decision on the part of the coalowners; and for the present, what would seem to have been a very sensible proposal on the part of the miners' representatives, for avoiding local stoppages and strikes in the future, falls to the ground.

*Barrow.*—There is still a very slow market in hematite pig iron. Business from all quarters is quiet, and there seems less disposition to order on home account, which has been the mainstay of the small trade which has been done for a considerable time past. Prospects for the winter months are not in any sense cheerful. Prices are weak at 45s. to 45s. 6d. for mixed Bessemer numbers, net f.o.b., and warrants are at 44s. 4½d. sellers, and 44s. 4d. buyers, net cash. The output of the furnaces is maintained, but there are only 33 in blast, 42 standing idle.

Iron ore is depressed in tone, especially as the local demand is very quiet, and as Scotch users are still requiring such small deliveries. Prices are easy, but are unchanged at 8s. 6d. for ordinary sorts, and 12s. to 13s. for best descriptions net at mines.

The steel trade is exceptionally quiet, and the outlook for the winter months, as in the pig iron trade, is very poor. Rails are still in quiet demand, and the orders held only represent a small trade generally. Plates are still in large production, and orders are fairly held. New business is offering, bnt prices are low. Tin-plate bars offer a better prospect. Billets and hoops are quiet. There is briskness in the steel casting department. Other branches of the trade are very quiet.

Shipbuilders and engineers are busy on Admiralty work generally, but they report a slow inquiry. Some orders have lately gone past Barrow at prices which are considered to leave no margin for builders. Ordinary mercantile marine work, however, is in very poor request. Engineers and boiler makers are very busy.

The extensions which have recently been made to the Kellner-Parlington Paper-pulp—Sulphite Process—Works at Barrow are nearly ready for operation. They will double the output of the concern, and the works will then be by far the largest concern of their kind in the country. There is a good trade in sulphite pulp.

The coal and coke trades are exceptionally quiet. The consumption is small on manufacturing and shipping account, but prices are steady, and there is no prospect of a reduction.

Shipping is depressed, both as regards imports and exports. Freights are low and unprofitable.

Traffic on local railways is poor.

There is a proposal at Barrow not only to increase the present gas plant, but to put down a public electric installation, for which the necessary parliamentary powers have been obtained.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

The condition of the coal trade in the South Yorkshire district remains as last reported; the demand is still up to the average, and the outlook is fairly cheerful. Not much is heard of the minor troubles in the coalfield, and it is hoped that the question of an advance in wages for topmen and pit lads will soon be settled. The other rupture—that of the enginemen—is still going on; and, although it was stated the men had decided to vote for the giving in of their notices if the coalowners did not accede to their requests, it is not thought that any general stoppage of work will ensue. This view is strengthened by what occurred at the meeting of the Executive of the Yorkshire Coalowners' Association, held at Sheffield on Tuesday, when the question came up for consideration. A request was made on behalf of the men that the coalowners should give them an interview. This was at once conceded, and a committee of the coalowners was appointed to meet a deputation of the Enginemen's Association. The position is a very simple one. Most of the enginemen obtained advances of 30 per cent. since 1888. Under the Conciliation Board arrangement they were required to submit to a reduction of one-fourth, leaving their advances at 22½ per cent. They declined to concede that reduction, holding that as they are not represented on the Board they are not bound by its decisions. They therefore require that their wages shall be fixed at 30 per cent. above the 1888 rates.

Now that the season is advancing, and the cold weather setting in, more business is doing in household sorts, and in view of the increase in prices this month, orders are more freely given. In the London markets 1s. per ton advance has already been obtained on the retail prices. Pits in this district have been sending a fair tonnage to the metropolis, and the returns are more regular. The advance in household coal has been reported as from 9d. to 1s. per ton, but this rise in values has not been generally made. One of our most important companies, who send an immense quantity into the London market, are still quoting lowest summer prices, and no change is expected in their case until next week. Other collieries are also supplying at September rates. The present quotations are:—Silkstones, 9s. 6d. to 10s. 6d. per ton; Barnsley House, 8s. to 9s. per ton; inferior qualities from 7s. 6d. per ton. The demand for steam coal is very large, and the most is being made of the remaining portion of the export season to the northern ports. An average tonnage in steam coal has been sent by the district pits, and when the projected railway extensions are brought into operation, the local coalowners will have a good deal more business in hand. Railway companies are taking a fair share of the average business, and the trade is fairly well maintained on the whole. Barnsley hards, 7s. 6d. to 8s. 3d. per ton; other qualities, 7s. per ton. Gas coal is plentiful, and in increasing demand at from 7s. to 8s. per ton. The trade in manufacturing fuel is quiet, large supplies causing prices to be as low as from 4s. 6d. to 5s. 6d. per ton. Pit slack in fair demand at 2s. 6d. to 3s. 6d. Smudge and small coal can be had at 2s. per ton. Prices of coke are well maintained, prices ranging from 8s. 6d. to 10s. per ton at the ovens.

It is locally reported that the improved tone which prevailed in the iron trade a fortnight ago has been maintained, but inquiries made this week fail to support that view. In fact, iron is perceptibly weaker. Hematites of the best quality do not make more than 53s. per ton, West coast, and from the North-east coast 51s. per ton. This is a fall of 1s. a ton on the prices current ten days ago. Common forge iron is now at 38s. 6d. a ton, a drop of 6d. per ton on the week. The reason for this weakness is not far to seek. Consumers are supplied for the moment, having placed their orders, and the promise of an improvement a short time ago encouraged makers to increase the output. Having now more than they want, they are competing with each other for such orders as are in the market.

Full employment is still being given in the armour plate mills, and there is an anticipation of further important work coming to hand shortly. A revival in the shipbuilding trade, which would give the much-needed stimulus to the marine material departments, is now more likely than at any time during the year. Considerable contracts have recently been placed for some large ships, and as foreign Governments are expected to strengthen their Navy, the result is certain to bring good business to this district. Some very good orders for Serve tubes for Atlantic-going steamers have been placed with Messrs. John Brown and Co. The settlement of the contracts for the new line to London has helped firms engaged in the production of the plant required by contractors for that purpose. Merchants who deal in second-hand rails, &c., also find a ready sale for their goods, owing to the number of new lines now being constructed. Hope is entertained of a general revival in railway material, both at home and abroad. Inquiries have of late been very large, and reports state that one company intends giving out a considerable order for rolling stock.

The quarterly return of exports from the Sheffield consular district to the United States exhibit a total value for the three months of £108,100 17s. 6d., as compared with £73,315 16s. 10d. for the preceding quarter. The total for the corresponding quarter of 1893 was £74,551. During the last quarter the new tariff has come into operation, and the result is particularly evident in regard to cutlery. The entire business in cutlery for the United States markets during the quarter ending June was only £6518 6s. 2d., while for the three months just ended the value is £42,677 1s. 2d. Steel has not been so much affected, the value for the quarter ending June having been £51,777 3s. 1d., as compared with £52,089 8s. 3d. For the previous quarter steel manufacturers expected that the new tariff would operate favourably, and one or two are already in receipt of better orders. Although these figures show a remarkable increase in cutlery, it must not be forgotten that the trade practically collapsed while the tariffs were in suspense, and that whilst stocks on the other side were brought down to almost nothing, the workmen here were engaged on American patterns, getting ready for the rush which was expected to come the moment the Wilson tariff came into operation.

An improvement is reported in the demand for cutlery from Brazil and the Argentine. The colonies, however, are sending few orders here. Ivory merchants and dealers state that they are not at all busy, except on orders for special lines. At this time of the year the silver and electro-plate firms put on more men to the Christmas trade. This industry is in a poor condition now, the aggregate output being far from the average. The makers of agricultural machinery have had a very good season, especially in reapers and mowing machines, owing to the exceptionally large harvest. The demand cleared out the stocks of some of our largest firms.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

The improvement in trade which has for several weeks been in progress has this week been checked in this district, and reports generally are unfavourable, as very little business can be done, and what is done is in some branches at a lower range of prices. The decline in prices has caused consumers to hold off, notwithstanding that the general trade of the country appears to be brightening up, as evidence of which we have the Board of Trade revenue returns, and the increased railway traffic receipts. But just now the fluctuations on the warrant market detrimentally affect business, and the tone has become very flat. The fact seems to be that the gradual return of the Scotch colliers to work leads some of those who have been speculating freely to think that they will not see any further advances in prices, and they are anxious to clear out, so as to secure the best possible profit on their transactions. At the first sign of an easing of prices, therefore, they began to put their iron on the market, and a large quantity was on offer. This served to help prices down, and made buyers the more resolved to wait. As a matter of fact the collapse of the Scotch colliers' strike should improve business in this district, because it will lead for a time to an increased demand from Scotland for Cleveland iron, seeing that the Scotch mills and forges will recommence operations as quickly as possible, and being unable to procure supplies of pig iron from native firms, owing to the stoppage of the blast furnaces, they will have to consume large quantities of Cleveland pig. It might have been expected that sellers in this district would have been able to have at least maintained their prices, but there has been so much speculation, and of late by unsubstantial and timid persons, that the course of the warrant market has had more effect upon the general market.

The adverse circumstances this week have chiefly affected the business in No. 3 Cleveland pig iron, which has been the quality in which most outsiders have been speculating, and it is this which is most freely offered for sale now. It is scarce in makers' hands, but that has not mattered, for second hands, though able to offer only comparatively small lots, have ruled the market. Makers would take 36s. 3d. per ton for prompt f.o.b. deliveries of No. 3 Cleveland G.M.B. pig iron, but there has been business done by second hands at 36s. 1½d., and even at 36s., this latter being 6d. below the best price recently paid. Cleveland warrants have fallen to 35s. 11d. cash, whereas 36s. 3d. was last week's closing price.

The stock of Cleveland pig iron in Connal's warrant stores at the close of last month was 89,745 tons, or 644 tons decrease for the month. The same firm held 62,766 tons of hematite pig iron in this district—an increase of 7000 tons in September, and of 19,449 tons in the last two months. For several months now the stock has been increasing not only in Connal's stores, but also, it is believed, in makers' hands and yet the production has been maintained. The prices of the commoner qualities of Cleveland pig iron have not fallen, makers being very well off for orders, and Scotch consumers are requiring more as they get their mills to work, while others are putting into stock in preparation for a start. Not long since grey forge was again becoming a drug upon the market; but this is not so now, and some makers are disposed to hold it rather than sell at the present price, for they say that will not pay them. It costs as much—and in some cases even more—to produce grey forge than to make No. 3, and yet the former is 1s. 6d. per ton cheaper than the latter, and has been 2s. cheaper until recently. No. 4 Cleveland foundry is at 35s. 6d., and grey forge at 34s. 6d. For mixed numbers of East Coast hematite pig iron 43s. 3d. is generally quoted, but business may be done at 43s., as there has been a considerable fall in warrants, buyers offering no more than 42s. 6½d. cash for them. Foreign ore prices, however, are maintained, 12s. 6d. being the figure for best Rubio, delivered in the Tees. The Normanby Ironworks Company have adopted the eight-hours' day at their furnaces, this making the fourth firm of ironmasters who have gone in for the three-shift system; but it is reported that, in one case, neither masters nor men are very well satisfied with the change. The Cleveland ironstone miners have decided to claim a 5 per cent. advance in their wages; but the masters cannot arrange to discuss the question with their executive until next month.

The September statistics of the Cleveland Ironmasters' Association, issued on Wednesday afternoon, were not worse than were expected, it being calculated that the increase in stocks would be between five and six thousand tons, and the actual increase was 5476 tons, but that certainly is not satisfactory for this season of the year, when there should be a substantial decrease. All the summer the returns have been unsatisfactory, the make exceeding the requirements, whereas the opposite should be the case. The total stock of Cleveland pig at September 30th was 192,185 tons, of which makers held, unsold, 96,205 tons—5150 tons increase; in makers' stores there were 2720 tons—30 tons decrease; in the North-Eastern Railway Company's stores, 3515 tons—1000 tons increase; and in Connal's, 89,745—644 tons decrease. Of the 141 blast furnaces in the district 95 were at work—one more than in August, Sir B. Samuelson and Co. having relighted a furnace at Newport—and of these 51 were making Cleveland pig, and 44 hematite, &c. The output of Cleveland pig was 122,358 tons—5373 tons increase on August—and of hematite, &c., 129,913 tons—increase 2527 tons; the total make was 252,271 tons—increase 7900 tons.

Pig iron exports from the Tees last month were rather better than were expected, reaching 80,139 tons—4416 tons increase in August, but 9824 tons decrease as compared with September last year. The quantity forwarded to Scotland was 24,105 tons, this being more than in August, but considerably below the average. In Russia, only 1695 tons were sent, whereas in September last year the quantity was 15,000 tons. To Germany also the quantity exported was less than usual—11,790 tons being forwarded direct, and 5947 tons *viâ* Holland. A much smaller proportion of the pig iron exported from the Tees has of late been of hematite quality than was the case last year, only 6860 tons out of the 80,139 tons last month being hematite, &c., whereas out of the quantity shipped in September last year 15,402 tons was hematite, &c., iron. The exports of manufactured iron and steel were fair last month, especially to India, which had 6128 tons of steel, and 996 tons of finished iron. To China 1178 tons of steel were exported, and to Japan 370 tons of steel, and 1128 tons of manufactured iron, notwithstanding the war. The total exports of pig and manufactured iron and steel from the Tees last month, as compared with August this year and September last year, have been:—

| | Pig iron. | Manufactured iron. | Steel. | Total. |
|---|---|---|---|---|
| | Tons. | Tons. | Tons. | Tons. |
| September, 1894 | 80,139 | 10,603 | 18,707 | 109,449 |
| September, 1893 | 89,963 | 9,569 | 19,161 | 118,693 |
| August, 1894 | 75,723 | 11,164 | 13,425 | 100,313 |

The manufactured iron and steel industries are very quiet, and producers have had to reduce their quotations, as they have found that they put them up rather too quickly, and checked the improvement that was setting in. Very little iron has been sold at the advanced rates, because consumers would not pay them. Iron and steel ship plates are at the same rates, and though £4 17s. 6d., less 2½ per cent., f.o.t., is generally quoted, there has been business at £4 15s. Angles are relatively dearer than plates, as one of the leading works is closed, and there is not so much competition. About £4 15s., less 2½ per cent., f.o.t., is the price for steel angles, and £4 12s. 6d., less 2½ per cent., for iron angles. Common iron bars are at £4 17s. 6d., less 2½ per cent., f.o.t. Heavy steel rails, £3 12s. 6d. net at works, with a little better prospect, a brisker inquiry being reported on export account. Bridge builders also speak more hopefully; they are generally well employed, and expect a considerable accession of work on export account. Some good orders have lately been secured by Staffordshire firms, and the competition is less keen than it was, so that more favourable prices are looked for. Engineers are running their establishments more regularly, but nevertheless the prospect for the winter is not very satisfactory, as the shipbuilders are not well off, half their building berths being unoccupied. Mr. Percy Sadler-Blair has been appointed managing director of Blair and Company, marine engineers, Stockton, in succession to his late father-in-law, Mr. G. Y. Blair, whose death was recorded last week.

The directors of Palmer's Shipbuilding and Iron Company, in their twenty-ninth annual report, state that since the re-organisation of the Board important changes have been made in the management of the staff, considerable economies have been effected in administrative charges, and improvements have been introduced into the work in order to lessen the cost of production. The company have delivered to the Admiralty the first-class battleship Revenge, one of the finest and most efficient warships afloat, and are now building three swift torpedo boat destroyers for H.M. Government, also a P. and O. steamer.

The steel works and blast furnaces have yielded improved results, and an amalgamation of the management of the two departments has been effected, whereby a considerable saving will be made. I understand that Mr. F. W. Dick is now the manager of these two departments. Mr. John Price, who has been head of the whole concern, has resigned his position, and is succeeded by Lieut.-Col. English. Additional capital to the extent of £200,000 is to be raised on the security of debentures in order to discharge the existing debenture debt of the company, which carries an onerous rate of interest, and part is to be applied to other purposes. It is now hoped to secure for the concern a renewal of prosperity.

The demand for coals is still active, and, though quieter than it was from Scotland, is yet heavy; in fact, the coalowners are sending less of their produce to London, and more to Scotland, because they can get better prices for it there. Northumberland best steam coal is 10s. 9d. per ton f.o.b., seconds 9s. 9d., and small 5s. An improving demand for gas coals is reported, and some large local contracts have been arranged for the Newcastle and Gateshead Gas Company at something like the combination price, 7s. 3d. per ton. Stockton Corporation have ordered 20,000 tons of screened coal from Broompark Colliery, 5000 tons from Thornley Colliery, and 4000 tons from Newfield Colliery, all at 9s. 1½d. per ton, and 1000 tons of unscreened coal at 8s. 9d. from Kimblesworth Colliery.

Coke is in excellent request, and the price is very firm at 12s. 6d. per ton delivered at the Middlesbrough furnaces, while 13s. 6d. to 14s. is the f.o.b. price. The North-Eastern Railway Company have decided to light Tyne dock—the largest coal shipping dock in the world—by electricity, and have placed the order for the work in the hands of Messrs. Crompton and Co., of London and Chelmsford. The installation will consist of two large boilers, two compound engines, three dynamos, sixty Crompton-Pochin arc lamps, with cable, posts, and all accessories.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

GLASGOW pig iron market was active in the early part of the week. Warrants were thrown upon the market owing to the break away of the miners from the control of their leaders. It was reported that upwards of 20,000 men have gone to work in the collieries of the West of Scotland, and the prospect of a cheaper and more plentiful supply of fuel led to an easier feeling in the market. The impression prevailed that prices had seen their highest for the present, and speculators were therefore disposed to unload. Scotch warrants declined from 43s. 3½d. to 42s. 10d.; Cumberland hematite from 44s. 2d. to 43s. 11d.; and Cleveland from 36s. 3½d. to 36s.

Makers' special brands being scarce, have changed very little in price. G.M.B. f.o.b. at Glasgow, No. 1 is quoted 45s. per ton; No. 3, 43s. 6d.; Monkland, No. 1, 48s.; No. 3, 44s.; Carnbroe, No. 1, 48s.; No. 3, 46s. 6d.; Summerlee, No. 1, 57s. 6d.; No. 3, 52s.; Calder, No. 1, 58s. 6d.; No. 3, 50s. 6d.; Coltness, No. 1, 58s. 6d.; No. 3, 51s. 6d.; Glengarnock at Ardrossan, No. 1, 54s. 6d.; No. 3, 49s. 6d.; Eglinton, No. 1, 54s. 6d.; No. 3, 48s.; Dalmellington at Ayr, No. 1, 50s. 6d.; No. 3, 50s.; Shotts at Leith, No. 1, 59s. 6d.; No. 3, 52s.

The output of pig iron in Scotland is still limited to the produce of three furnaces making ordinary iron at Coltness. The furnacemen have suffered much through enforced idleness during the colliers' strike, and it is believed the ironmasters will set them to work as soon as possible. Some weeks must elapse, however, before the output is materially increased. The demand will be largely for hematite pig to supply the steel works, and inquiries are now being made for steamers to import hematite ore from Spain. The first charters made for three months have been effected this week, the rate paid from Bilbao to Glasgow being 5s. 3d. per ton, or 1½d. more than to Middlesbrough. There is a steady although not a very large consumption in Cleveland iron, and this is likely to increase.

The pig iron shipments are very small, being only 2566 tons, against 4225 tons in the corresponding week. There was sent to Canada, 500 tons; Italy, 320; United States, 50; India, 115; Australia, 60; France, 10; Germany, 150; Holland, 110; Belgium, 20; China and Japan, 325; other countries, 31; the coastwise shipments being 875 compared with 680 tons in the corresponding week.

The market for finished iron and steel so far exhibits little change; makers are, however, looking forward to an improved inquiry, and they are getting their works put into order, so that they may be in a position to meet any demand that may arise.

The exports of manufactured iron and steel in the past week embraced sewing machines worth £6550; machinery, £5600; steel goods, £1958; and miscellaneous iron goods, £5610.

Under the auspices of the British Iron Trade Association it has been arranged that a conference of representatives of the iron and steel trades shall be held in Glasgow on the 30th instant. Mr. William Jacks, M.P., president of the association, will preside, and a number of subjects will be introduced and discussed bearing upon the prospects of trade and foreign competition. The miners of the West of Scotland have returned to work in large numbers, notwithstanding the resolution of the Edinburgh Conference of the British Federation that the strike should be continued at some places, notably in the Motherwell district. The men have made quite a rush for the pits, fearing that places might not be readily found for them. There does not now seem any likelihood of the leaders being able to rally the men, and the belief is that in a very short time they will be all back to work.

The coal market is much easier, as supplies are rapidly increasing, and prices will soon be back to a level that will allow of free purchases for manufacturing purposes.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE one prominent subject of discussion on Monday was the "Fate of the Sliding Scale." On Saturday, at the audit meeting held in Cardiff, under the presidency of Mr. W. Abraham—"Mabon"—in the absence of Sir W. T. Lewis, a declaration of 1¼ per cent. reduction was announced as a result of the audit of the coalowners' books for July and August, the reduction dating from 1st October.

At the same meeting of coalowners' and colliers' representatives, the following notice was handed in:—"To the members representing the Coalowners' Association upon the Sliding Scale Joint Committee. Gentlemen,—We, the undersigned, hereby give you six months' notice that the existing sliding scale agreement, now in force, regulating the workmen's wages at the South Wales and Monmouthshire collieries in the Coal Association, will terminate on the 31st day of March, 1895. Dated 1st October, 1894. (Signed) W. Abraham, D. Morgan, D. Beynon, Thos. R. Thomas, Alfred Onions, T. Darounz Isaac, Isaac Edwards, John Morgan, Thos. Richards, Philip George, Thos. Davies, Lewis Miles."

The coalowners, upon receipt of this ominous notice, agreed to defer the consideration of any questions arising out of it until a future meeting. When the reduction and the giving of notice was made known in the district, many well-disposed colliers regretted that at such a crisis a reduction should have been declared, quite ignoring the fact that the scale is built up upon rigid and impartial foundations, and could not be swayed from the straight line for purposes of policy. As this dawns upon the men, I have hopes that they will agree eventually not to abandon the principles of the scale, which have yielded them regular work and good pay for seventeen years. The last reduction now leaves the colliers' wages at 22½ above the standard. The impression amongst leading coalowners is that September and October audit will be to declare a small advance.

Last week's coal shipments were a good deal above the average at Cardiff; and Newport and Swansea exhibited large returns, the latter still keeping above the average, but in patent fuel there has been a falling off. At Cardiff prices slightly drooped towards the close of the week, and quotations were given at 11s. 6d. to 11s. 9d. for best steam. This week they have recovered firmly, and the latest figures were 11s. 6d. to 12s. Seconds 11s. to 11s. 3d., dry sorts 10s., ordinary small 4s. 9d. to 5s. 3d., best small 5s. 6d. to 5s. 9d. All figures were firmly maintained. In house coal a brisk demand is setting in, and prospects of a vigorous trade in the next few months are very certain. Ruling prices, Cardiff, were, for best house, 11s.; No. 3 Rhondda, 10s. 3d. to 10s. 6d.; brush, 8s. 6d.; small, 6s. 6d. to 6s. 9d.; No. 2 Rhondda, large, 8s. 9d.; through, 7s.; small, 4s. 6d. to 4s. 9d. Patent fuel remains steady at 11s. to 11s. 3d., Cardiff. Swansea prices are 10s. 6d. to 11s. Other quotations of the week are, Cardiff—Coke, furnace, 15s. 6d. to 16s.; foundry, 17s. to 18s.; special foundry, 20s. to 21s. Pitwood is in excellent demand, as can be seen by the quantities on rail, and the accumulations being made at the collieries. Good wood realises 15s. 3d. to 15s. 6d., ex ship; Swansea prices are 17s. into truck, net cash 30 days.

Swansea harbour returns show an increase of 14,000 tons for last week, as compared with those of the corresponding week last year.

The great feature in the tin-plate trade at Swansea is the large increase taking place in shipments. Last week the biggest shipment on record to Russia took place, no less than 3000 tons being despatched to Batoum by the Hebron. This, and the improvement in the American trade, are gratifying facts, and if workmen now subdue the disposition to hamper trade, and work energetically with their employers, better prices and wages must follow. I note that last week the total tin-plate shipment was 123,275 boxes, while the quantity sent in from works only totalled 68,081 boxes. This again reduces stocks, which are down to 227,311 boxes, as compared with 282,585 boxes last week. It will be seen from this that it is now more a question of clearing out stocks than of increased animation at the works, but I quite agree with the opinion on 'Change, Swansea, that a little more depletion must alter figures.

There is little change to report in the iron and steel trades. Increased briskness is to be noticed in stocking foreign ore—the usual forecast of the coming events. All the principal works have figured largely during the week, amongst them "Tredegar." This by some is taken as an indication that a movement is probable amongst the "dry bones." I should only be too happy to verify, but find that the name of the vessel was Tredegar. The shipment was to Tapson and Co. In the coal development, as at Rhymney, the Tredgar Company are doing well, and it is fortunate that the ironwork companies have two strings to their bow, and can afford to wait. It is, however, more than local rivalry that they have to contend against. Cyfarthfa with its remarkable management, and Dowlais with its sea-shore advantages, are great factors; but I find that northern opposition is getting keener, and many instances have occurred of late where the Welsh ironmaster has been successfully opposed by his northern rival. This week large cargoes of tin bars have come into Swansea, and 700 tons pig from Millom, and a quantity from other quarters, with scrap steel from Port Glasgow.

Pig iron warrants have further declined at Swansea during the week. Lowest figure has been 42s. 10d.; Middlesbrough, No. 3, 36s. 1½d.; hematite, 43s. 11½d.

Other quotations, mid-week, were:—Welsh bars, £5 to £5 2s. 6d.; sheet iron, £6 to £6 10s.; steel sheets, £6 5s. to £6 7s. 6d.; Bessemer steel bars, £4 2s. 6d.; Siemens best, £4 to £4 2s. 6d.; all delivered in the district cash, less 2½. Steel rails, heavy, £3 15s. to £3 17s. 6d.; light, £4 10s. to £4 15s.

Makers' quotations for tin-plates are:—Bessemer steel cokes, 10s. 3d. to 10s. 6d.; Siemens, 10s. 6d. to 10s. 9d.; ternes, per double box, 28 by 20 c., 20s. to 24s.; best charcoal, 12s. to 12s. 6d.; wasters, 6s. to 1s. less than primes.

Block tin is at £70 5s.

Iron ores slightly changed—Tafna, 11s.; Rubio, 11s. 3d. to 12s. per ton ex ship; 1s. 6d. extra for selected large per ton, Swansea.

It is expected that the wage reduction by American ironmasters and "tin-plate" makers to their workmen will have the effect of sending a large number of Welshmen home to their old industries.

"The dispute at Llanbradach" was one of the subjects keenly discussed on "Mabon's" day at the Caerphilly meeting, and South Wales colliers were appealed to keep away and not interfere. The contention is that the price list offered to the men wants improving.

Reduced rates on pitwood have come into force this week on the Great Western Railway from Swansea. The tariff reduction is from 3d. to 9d., and considerable local benefit is anticipated.

Up to the present pitwood quotations at Swansea are higher than at Cardiff, though Swansea is a tide nearer the supplies. This anomaly may now be corrected.

At Bangor, North Wales, the Corporation have acquired the Anglesey Ferry by purchase. It is intended to erect a pier at an expense of £10,000, for which the necessary parliamentary power has been obtained.

Some slight hitch has occurred at one of the Plymouth collieries this week. The hauliers are credited with the difficulty.

There has been a Congress of the Amalgamated Society of Railway Servants at Newport, Mon., and a reception by the Mayor. The leading feature on the first day was the election of president, Mr. Hudson for the fourth time obtaining that honourable distinction. The leading points of discussion at the Congress were to be the abolition of the seven-day system and the establishment of an eight-hour day.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

BUSINESS, all through the iron and steel trade, continues generally quiet. For some sorts of iron there was perhaps some little extra inquiry here and there, which may be traceable to anxiety on the part of users to cover themselves against any possible contingency which might arise through stoppage of works or restriction of output; but, on the whole, there was no real weight of buying going on, and quotations are but moderately maintained.

In Silesia the business in pig iron has improved; some fair export orders have been booked recently, one for 3000 t. for an Austrian works, and there are more contracts holding out, so that makers have fairly good prospects for the immediate future. The rolling mills have also got some fresh orders, but, to secure them, manufacturers had to reduce their quotations. Breslau dealers now ask M. 120 p.t. for girders, which is about M. 10 less than was formerly quoted. On the whole, there are more offers than inquiries in all branches of the iron trade.

In Austria-Hungary the iron industry presents no new feature. Pig iron continues rather scarce, and the Rima Muranga Iron Company have even been compelled to order 3000 t. from Silesia. The works producing rails and railway requirements are still but weakly engaged, demand being altogether insufficient, while prices are, naturally, wanting in firmness.

Iron business in France has improved, although, for the present, small lots only are sold; but there is quite a confident tone noticeable in all departments, and the tendency of prices is good, especially when compared to June and July of present year. The iron foundries are all reported in regular employment. In Paris merchant bars have been sold at 155f. p.t.; girders, at 65f. p.t.; while free at works prices are about 8f. to 10f. lower. In the Departement Nord the market is more quiet, and for orders of some weight prices are decidedly less firm.

On the Belgian iron market, the tone of the malleable iron business is tolerably satisfactory, while makers of pig iron have to fight against the almost crushing competition of Luxemburg and Longwy; and some of the larger firms—Athus, for instance—found themselves obliged to agree to a reduction, and are now selling forge pig at 43f. p.t., instead of 44f. p.t., although the prices of coke have risen lately, and a considerable firmness is exhibited in the finished iron trade. Of 42 existing blast furnaces, 29 were in blow on September 1st, 13 producing forge pig, 3 foundry pig, and 12 producing basic. The following shows the output of pig iron in August, and for the first eight months of present year and of the year before:—

| | August. | | January to September. | |
|---|---|---|---|---|
| | 1894. | 1893. | 1894. | 1893. |
| | Tons. | Tons. | Tons. | Tons. |
| Forge pig | 37,820 | 33,480 | 263,640 | 259,200 |
| Foundry pig | 6.820 | 6,510 | 52,800 | 50,400 |
| Basic | 35,650 | 20,150 | 276,300 | 156,000 |
| Total | 40,490 | 60,140 | 592,740 | 465,600 |

Makers of steel report themselves in a somewhat better condition than a few weeks ago, and some firms are contemplating the enlargement of their establishments, so that production will increase in the next quarter. The following table shows prices—in francs—of Belgian coal and iron, per ton at works, since 1875:—

| | Coal. | Foundry pig. | Bars, No. 1. | Plates, No. 2. |
|---|---|---|---|---|
| 1875 | 15·50 | 70 | 176 | 242·50 |
| 1876 | 14·30 | 62·25 | 150 | 226 |
| 1877 | 11·90 | 56 | 132·50 | 190 |
| 1878 | 10·20 | 55·75 | 124 | 177·50 |
| 1879 | 9·45 | 49·10 | 115 | 154 |
| 1880 | 10·20 | 54·20 | 156 | 205 |
| 1881 | 10·55 | 54 | 125·50 | 171 |
| 1882 | 10·37 | 58 | 134·50 | 187·50 |
| 1883 | 10·62 | 57 | 120·50 | 176 |
| 1884 | 9·80 | 49·50 | 117 | 159 |
| 1885 | 9·05 | 47·25 | 107 | 143 |
| 1886 | 8·30 | 43 | 102·50 | 126 |
| 1887 | 8·25 | 45·50 | 112 | 133 |
| 1888 | 9·50 | 51·25 | 120 | 140 |
| 1889 | 10·90 | 57·25 | 129 | 151 |
| 1890 | 16·55 | 67·25 | 160 | 181·50 |
| 1891 | 13·60 | 51·75 | 131 | 149 |
| 1892 | 11·15 | 50 | 117·50 | 135 |
| 1893 | 10·12 | 48·25 | 110 | 128·75 |
| 1894 | 10·70 | 49 | 110 | 130 |

The Rhenish-Westphalian iron market shows, on the whole, the same feature as in former weeks, and buyers still show little inclination to purchase more than what is immediately required. On the iron ore market demand is moderate, and the prices tolerably well maintained. Spathose iron ore is paid with M. 7·40 to 7·70 p.t., roasted do. fetching about M. 10 to 11 p.t at mines, inferior qualities are quoted M. 9 to 10·20 p.t. at mines. Nassau red iron ore meets with a fair demand, the 50 p.c. grade being quoted M. 9 20 p.t. free Dillenburg. For Luxemburg-Lorraine minette prices vary from M. 2·40 to 3·20 p.t. net at mines. In pig iron a pretty regular business has been doing upon the week, small lots being sold at comparatively firm quotations. The prolongation of the Rhenish-Westphalian Pig Iron Convention till July next year is regarded as a sort of guarantee for the future development of the iron market.

In the Siergerland the iron business is quiet just now; the following prices are quoted:—Spiegeleisen, 10 to 12 p.c. grade, M. 52 p.t.; Rhenish-Westphalian forge pig, No. 1, M. 46 to 47; No. 3, M. 40; Siegerland, good forge quality, M. 44; hematite, M. 63; foundry pig, No. 1, M. 63; No. 3, M. 54; basic, M. 46; German Bessemer, M. 49 to 50 p.t.; at works. Iron for making steel, Siegerland brands, M. 45 p.t.; Rhenish-Westphalian brands, M. 47 p.t.; Luxemburg forge pig costs M. 48 p.t., free Luxemburg.

In the malleable iron department the demand is quiet, especially in bars, and prices are somewhat depressed. Much the same can be told of girders. The hoop trade is in an improving condition compared with last week, and a generally stiffening tendency in prices can be noticed, which may be accounted for by the increasing weight of new work that has been coming forward lately. The activity at the plate mills continues satisfactory, though certainly not remunerative; the same holds for sheets. In the wire and wire nail branch both demand and prices leave very much to be desired; and the rivet business has also been very quiet for some time past, the few orders that are actually booked being mere trifles. Machine and wagon shops are irregularly and, for the most part, unsatisfactorily occupied.

Latest list quotations, per ton at works, are as under:—Good merchant bars, M. 105 to 110; angles, M. 125; girders, M. 90 to 95; hoops, M. 108 to 115; billets, in basic and Bessemer, M. 81; heavy plates, for boiler-making purposes, M. 150; tank, do., M. 130 to M. 135; steel plates, M. 125; tank do., M. 115 to 120; sheets, M. 120 to 150. Iron wire rods, common quality, M. 115 to 120; drawn wire, in iron or steel, M. 105 to 120; wire nails, M. 125; rivets, M. 150; steel rails, M. 112 to 115; steel sleepers, M. 106; fish-plates, M. 115; complete sets of wheels and axles, M. 270 to M. 280; axles, M. 220; steel tires, M. 215 to 230; light section rails, M. 95.

The total production of pig iron in Germany, including Luxemburg, was, for August of present year, 489,211 t., of which 133,266 t. were forge pig and spiegeleisen, 37,023 t. Bessemer, 239,466 t. basic, and 79,456 t. foundry pig. Production in August, 1893, was 420,949 t.; in July, 1894, it was 476,894 t. From January the 1st to August 31st of present year no less than 3,615,176 t. were produced, against 3,236,680 t. for the same period the year before.

## AMERICAN NOTES.

NEW YORK, Sept. 27th, 1894.

THE slacking up in demand for iron, steel, and railway material, at a time when a general expansion of demand was expected, has been a surprise to manufacturers and brokers. The general election occurs within six weeks, and it is believed that will be a sweeping Protectionist victory. The effect will naturally be to stimulate demand in all channels of trade. Railroad managers are completing their requirements for the coming year, and large contracts will soon be placed, covering rails, track equipments, engines, cars, and machine shop machinery. Steel billets are declining, and when they touch sixteen dollars at Pittsburgh, large orders for fall and winter delivery will be placed. Prices are weak in all channels, and the banks have more money than they have use for. Business men are discouraged at the slow growth of trade. Merchant bar mills are running out of business. The production of anthracite coal is 1,500,000 tons less than at this date last year. Coke production is now 105,000 tons per week.

DURING the recent summer months, in Westminster, the sun was shining for 803 hours, which is 130 hours less than the average during summer for the ten years 1881 to 1890. The greatest deficiency was 39 hours in August, and in May there were 32 hours less than usual, while September was 29 hours below the average. In the Channel Islands the sun was shining for more than 1100 hours, and in the south-west of England for upwards of 1000 hours. In Scotland, Ireland, the North of England, and in the Midland Counties, the amount was only slightly in excess of 800 hours, or very near the record for London.

## LAUNCHES AND TRIAL TRIPS.

On Saturday afternoon, the 29th inst., Alderman Charlton, J.P., launched from his yard on the west side of the Royal Dock a handsomely modelled iron screw steam trawler. The dimensions of the vessel are—Length 102ft., beam 21ft. and depth 11ft. The machinery will be supplied by the builder, consisting of the triple expansion engines, with cylinders 12¼in., 20in. and 32in. by 22in. stroke, and are supplied by steam at 155 lb. pressure by extra large steel boiler fitted with Holmes' furnaces. The vessel will also have powerful steam winch specially made for steam trawlers by the builder, and of which a great number have been made. There is a comfortable cabin aft for the captain and engineers, also a roomy forecastle, which shows the builder has studied the comfort of the crew. The ceremony of naming the vessel Agnes was performed by Miss May Collingwood, and we are pleased to say the launch was successful in every way. The vessel was towed into the Alexandra Dock, where she will have her machinery put on board.

On Saturday afternoon there was launched from the East Yard of Messrs. C. S. Swan and Hunter, Wallsend-on-Tyne, a large steel screw steamer, which has been built to the order of Messrs. Christian, Michelson, and Co., of Bergen. The dimensions of this vessel are 341ft. by 44ft. by 29ft. 10in. She has been constructed to take the highest class at Lloyd's, and will carry about 5500 tons deadweight, thus constituting Messrs. C. Michelson and Co. the owners of the largest steamer under the Norwegian flag. In the design of the steamer special attention has been paid to details relating to expeditions, manipulations of cargo, and 'tween decks of unusual height, viz., 8ft. 6in., have been provided, so that the vessel will be admirably adapted for emigrant requirements, or for the conveyance of horses, cattle, or troops. The vessel will be supplied with triple-expansion engines by the North-Eastern Marine Engineering Company, Wallsend, the cylinders being 34in., 40in., 64in., by 42in. stroke, with two large steel boilers working at a pressure of 160 lb. During construction the steamer has been inspected and superintended by Captain Rodseth on behalf of the owners, and on completion this gentleman, who is a seaman of wide experience, will take command. The steamer was named the Solveig by Mrs. Anderson, of Newcastle.

On October the 2nd, 1894, Messrs. Furness, Withy and Co., launched from their yard at Hartlepool a large screw steamer, built to the order of Messrs. Burdick and Cook, London. She is a fine type of a modern cargo boat, measuring over 280ft. in length, and built throughout of iron, with a large measurement and deadweight capacity, and built to the highest class at Lloyd's. The vessel has a long raised quarter deck, short poop, long bridge-house and a topgallant forecastle. The holds are fitted with iron grain divisions, and all decks, deck erections, skylights, bulwarks, bulkheads, &c., are constructed of iron. Cellular bottom fitted all fore and aft for water ballast. The greater portion of the plates are in 24ft. lengths, making the structure of the ship very strong. Four steam winches, one donkey boiler, patent steam steering gear amidships, screw gear aft, patent windlass, stockless anchors, hauling into hawse pipes, and other modern appliances are fitted for the handy working of the vessel. The saloon and cabin providing accommodation for the captain, &c., is handsomely finished in polished hardwood, with a number of hand-painted panels, executed in an effective style by the staff of ladies employed by the firm. The steamer will be rigged as a two-masted fore-and-aft schooner, and has been constructed under the personal supervision of Mr. J. Cook. She will be fitted with triple-expansion engines by Messrs. Blair and Co., Stockton-on-Tees. On leaving the ways she was named Nellie by Miss Lindsley, of Hartlepool.

On Saturday afternoon, the 29th ult., Messrs. Craig, Taylor, and Co. launched a very handsome steel screw steamer, which has been built to the order of Mr. Joseph Hoult, of Liverpool. The dimensions are 342ft. by 43ft. by 29ft. 9in. depth moulded to the spar deck, with full poop, long bridge, and top-gallant forecastle. She is built to the highest class in Lloyd's, and has six large steam winches, multitubular donkey boiler, direct-acting steam windlass, patent steam steering gear, and all modern improvements. One of her special features is the large quantity of water ballast, being fitted with tanks to carry no less than 1250 tons. In addition to the ordinary cellular bottom, the vessel is fitted with a deep tank abaft the engine-room, which can be utilised either for carrying water ballast or any description of cargo, being fitted with large hatches, also a special system of ventilation, so as to obviate the difficulty so frequently occurring in those deep tanks. The vessel is rigged as a two-masted schooner, with telescopic masts, and carries about 5500 tons deadweight, with large cubical capacity. The engines and boilers, which are constructed for a working pressure of 200 lb., are being built by Messrs. Thos. Richardson and Sons, Hartlepool. This vessel, which has been built under the superintendence of Mr. A. C. Hay, of Liverpool, is the third built by these builders for Mr. Hoult, and they have another similar one on the stocks. As the vessel was leaving the ways she was named the Benrath by Mrs. Pyke, of Southport, who was presented with a very pretty bouquet by Master Robin Craig.

The s.s. Ranza, which was recently launched by Messrs. Palmer's Shipbuilding and Iron Company, went on her trial trip on 27th ult. She has been built to the order of the Caledonia S.S. Company, Liverpool, under the superintendence of Messrs. Flannery and Blakiston, of Liverpool and London, and is of the following dimensions:—Length, 410ft.; breadth moulded, 49ft.; depth moulded, 34ft. The vessel is estimated to be capable of carrying fully 8000 tons deadweight on Lloyd's summer freeboard. She has been built to Lloyd's highest requirements, and her machinery, which has also been supplied by Messrs. Palmers, is of ample power, and developed a mean speed of 11½ knots on the trial in light condition. Her engines have cylinders 27in., 44½in., 73in. by 48in. stroke; steam is supplied by three single-ended boilers fitted with Eaves' patent induced draught arrangement. This system consists of assisting the draught by induction, the fans being placed upon the chimney side of the fire, and it is claimed that the intensity of local heat arising from forcing fires by pressure of air below them is avoided under this system. The Ranza is the fifth vessel fitted with it, and considerable interest attaches to the result. In addition to the main boilers, the donkey boiler is fitted so as to supply steam to the intermediate steam chest, and thus in case of need assist supplying steam for the propulsion of the ship.

On Monday there was launched from the Cleveland Dockyard of Sir Raylton Dixon and Co., Middlesbrough, a very fine steel screw steamer, which has been built to the order of Messrs. David MacIver, Sons, and Co., of Liverpool and London, for their River Plate Line. This is the second of three sister vessels which these builders are now constructing for the same owners, all of which have been specially designed and fitted for the River Plate trade, comfortable and well-ventilated accommodation for the passengers being fitted up in the poop. The vessel is of the partial awning deck type, with long raised quarter-deck and poop, and has been built under special survey for Lloyd's highest class, the principal dimensions being 305ft. by 41ft. 3in., by 20ft. 3in., with a deadweight carrying capacity of over 3500 tons on a very light draught of water, and all the deck erections are so arranged that the steamer can be promptly adapted for the purpose of carrying cattle. She will be rigged as a fore-and-aft schooner, with Sidgwick's patent hinged topmast, which can be immediately lowered when the steamer is required to pass under such obstructions to navigation as the permanent bridges over the Manchester Ship Canal. The engines will be fitted by Messrs. Blair and Co., of Stockton, the cylinders being 23in., 37in., and 61in. by 42in., with two large steel boilers working at 160 lb. pressure; and as the vessel is of fine model, a good sea speed will be economically maintained. The steamer has been built under the superintendence of Mr. P. H. Roscoe, of Liverpool, superintending engineer to the owners. As the vessel was leaving the ways she was named the Normandy by Miss Raylton Dixon, the daughter of the builder. The owners were represented by Mr. Charles Livingston.

## A NEW METHOD OF REDUCING METALLIC OXIDES.*

By H. W. Greene and W. H. Wahl.

Among the reducing agents commercially available for the producing of maganese from its oxides in a state free from carbon besides aluminium, which has already been applied by the authors, silicon is obviously the most likely one, as the heat developed by its oxidisation to $SiO_2$ is sufficiently in excess of that required to reduce 2MnO to permit the supposition that the desired reaction would take place. As, however, pure silicon can only be obtained by complicated and costly means, the direct use of this re-agent is out of the question, but it is different with metallic silicides such as ferro-silicon and silicon spiegel, which contains large proportions—5 to 30 per cent.—of silicon with comparatively little carbon, as the latter diminishes as the former increases. These silicides the authors propose to employ in the production of ferro-maganese and maganese steel, which latter substance under the present condition of manufacture, where ordinary ferro-manganese is added to fluid iron, is limited in its manganese contents by the carbon, 5 to 6 per cent., which is present in the ferro-manganese, and which cannot be eliminated from the steel on account of the affinity of the manganese for carbon.

The chemistry of the operation is exceedingly simple. When ferro-silicon is heated in a crucible or furnace lined with lime or magnesia in contact with a metallic oxide or a mixture of such oxides with lime, magnesia and a lumina for fluxing, the silicon is oxidised by the oxides, and combines with the fluxes to form a slag, while the metals set free combine to form an alloy. Assuming the oxide to be that of manganese, as MnO or $Mn_3O_4$, and the silicides to contain—iron 88, silicon 10, and carbon 1 per cent., the proportions required to satisfy the equation—$2MnO + Si = SiO_2 + 2mn$—will be 142 of manganese to every 28 parts of silicon in the silicide, and sufficient earthy oxides to form a properly fusible slag with the silica produced. A further amount of manganese oxide will, however, be necessary, as a certain quantity is invariably taken up by the slag, and so escapes reduction. An experimental charge, containing;—

| | Lbs. |
|---|---|
| Ferro silicon (Si 10, C 1 per cent.) .. .. | 100 |
| Manganous oxide .. .. .. .. .. .. .. | 70 |
| Lime .. .. .. .. .. .. .. .. .. .. .. | 50 |

Yielded 128 lb. of an alloy, containing—

| | Lbs. |
|---|---|
| Iron .. .. .. .. .. .. .. .. .. .. | 70·0 |
| Manganese .. .. .. .. .. .. .. .. | 29·0 |
| Carbon .. .. .. .. .. .. .. .. .. | 0·7 |
| Silicon .. .. .. .. .. .. .. .. .. .. | trace |

Assuming that the permissible carbon in a manganese steel is 0·5 per cent., 100 lb. of such an alloy when added to 40 lb. of decarburised iron will give 140 lb. of manganese steel of the composition—iron 78·8, manganese 20·7, carbon 0·5, silicon trace.

In the preparation of manganese steel of the same carbon temper with ordinary ferro-manganese—80 manganese to 5·5 carbon—the resulting metal would contain 92·3 iron and only 7·27 manganese. On the basis of equivalent contents of manganese, 20·7 per cent. of manganese would bring in 1·4 per cent. of carbon, using ordinary ferro-manganese, while by the author's method, 7·7 per cent. manganese would correspond to only 0·18 per cent. of carbon. By using the oxides of other metals with ferro-silicon, iron alloys with more than 50 per cent. of nickel, with nearly 20 per cent. of chromium, and more than 50 per cent. of tungsten have been obtained, all being relatively low in carbon. Titanium has so far only given doubtful results. Alloys of copper with difficultly reducible metals may be similarly obtained by fusing their oxides with copper silicide.

H. B.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

*20th September*, 1894.

17,856. Apparatus for Drawing to Scale, A. G. Ashcroft, London.
17,857. Thief-proof Window Bolt, J. Goulson, Liverpool.
17,858. Muzzle for Race Horses, J. P. Byrne, Wicklow.
17,859. Metallic Buttons, B. Shorthouse, Birmingham.
17,860. Making Soap and Glycerine, J. K. Hill, Irvine.
17,861. Brakes for Velocipedes, V. Collinson, Lancashire.
17,862. Flushing Water-closets, C. Smith, Manchester.
17,863. Pin for Crimping, &c., Hair, W. McCrag, Glasgow.
17,864. Cycles, A. King, Nottingham.
17,865. Tippers of Water-closets, W. Whitaker, jun., Halifax.
17,866. Cycle Frames, C. E. Bell, F. W. Killingbeck, and H. L. Parkinson, Manchester.
17,867. Self-acting Mules, &c., R. Clegg, Manchester.
17,868. Making Paving Slabs, C. and A. Musker, Liverpool.
17,869. Furnaces, J. J., T. F., and J. W. Meldrum, Liverpool.
17,870. Cycle Steering Heads, C. Binks and The Central Engineering Works Company, Limited, York.
17,871. Rolling Axles, J. F. Johnson and E. Broadhead, Sheffield.
17,872, Cure of Phthisis, H. Pott, Birmingham.
17,873. Dowson Gas Enricher, H. T. Blake, Herefordshire.
17,874. Machining the Bevels of Stem Bars, D. Sheret, Hebburn-on-Tyne.
17,875. Radiators for Heating, W. H. Hargreaves and R. H. Dewhirst, Bradford.
17,876. Apparatus for Drying Wheat, H. Clarke, Burslem.
17,877. Conveyance of Petroleum in Ships, C. C. Murray.—(*J. D. Murray, Straits Settlements.*)
17,878. Automatic Railway Signalling J. Dennison, Newton.
17,879. Swings, F. Lockwood, Burnley.
17,880. Umbrella Suspender, A. G. Sadd, Ipswich.
17,881. Manufacture of Umbrellas, M. Tallefer, Liverpool.
17,882. Manufacture of Cut Nails, C. March, Glasgow.
17,883. Piston Pumps, C. P. H. Gzoon, Leipsig-Gohlis.
17,884. Sockets in Sanitary Pipes, W. Ingham and B. Langton, Leeds.
17,885. Calico-printing Machinery, M. McPhail, Glasgow.
17,886. Gas-meters, R. C. Williams, London.
17,887. Bed-pan, C. W. Surridge, London.
17,888. Tires for Cycles, J. W. Radford, London.
17,889. Advancing and Retiring Motion, H. L. Symonds, London.
17,890. Governing Speed of Steam, D. Parry, London.
17,891. A Rapid Cycle, A. Fasoli and O. Negri, Croydon.
17,892. Military Water-bottles, J. Menzies, London.
17,893. Valves, A. H. Mitchel-Jones, London.
17,894. Bellows for Cameras, A. H. Mitchel-Jones, London.
17,895. Cameras, A. H. Mitchel-Jones, London.
17,896. Apparatus for Washing Casks, R. G. White, London.
17,897. Umbrellas, W. A. Bindley and W. J. Gell, London.
17,898. Dress-holders, H. W. J. Cheffins, London.
17,899. Making Gloves, T. Billson and W. Partridge, London.
17,900. Knee-caps for Horses, J. J. Wilson, Birmingham.
17,901. Preserving Surgical Ligaments, C. Repin, London.
17,902. Lamps, H. B. Gurney, London.
17,903. Glasses and Shades for Lamps, M. Balson, London.
17,904. Sanitary Shell, J. Birch, London.
17,905. Imitation Whalebone, J. Baier, London.
17,906. Apparatus for Washing Wool, J. C. Walker, Bradford.
17,907. Apparatus for Washing Wool, J. C. Walker, Bradford.
17,908. Velocipedes, C. M. Linley, J. Biggs, and J. Archer, London.
17,909. Castor, A. Kirmse, London.
17,910. Cigar-lighter, T. Harris, Plymouth.
17,911. Apparatus for Treating Yarn, L. Wilson, Manchester.
17,912. Leg Guards, W. C. Nickels, London.
17,913. Frost Nail for Horses, C. Watkins and W. B. Healy, Birmingham.
17,914. Eyes for Stair-rods, W. Klinge, London.
17,915. Braces, G. W. Wernham, London.
17,916. Scarf-pins, A. Grollmann, London.
17,917. Hats, E. H. Andrews, London.
17,918. Boots, P. M. Hooper, London.
17,919. Matches, H. J. Köster, London.
17,920. Fireproof Floorings, W. Clark and A. W. Rammage, London.
17,921. Cooking and Roasting Utensils, I. Eades, London.
17,922. Arc Lamps, M. Immler, London.

*21st September*, 1894.

17,923. Preventing Robbery from Pillar-boxes, R. J Pleace, London.
17,924. Photographic "Blind Shutters," H. R. Cook, Cork.
17,925. Printing Textile Fabrics, J. G. Sanderson, Manchester.
17,926. Traction Power Multiplication, N. C. Lindsay and H. Stanbridge, London.
17,927. Starting Rods of Spinning Mules, J. Lees, Ashton-under-Lyne.
17,928. Knife Cleaner and Sharpener, H. C. Williams, London.
17,929. Hinges, D. Smith, Dundee.
17,930. Cleaning Knives, &c., H. and J. W. Bower, Keighley.
17,931. Cranks for Cycles, G. Pirnie, Dundee.
17,932. Wrenches, F. J. Burrell and J. A. Woods, Thetford.
17,933. Driving Chains for Cycles, W. Starley, Coventry.
17,934. Wheels for Road Vehicles, J. G. Harrison, Birmingham.
17,935. Tightening Clothes Lines, J. Pickford, Manchester.
17,936. Dredgers, J. Gillespie.—(*C. A. Marchant, India.*)
17,937. Extracting Juice from Canes, J. Drummond, Glasgow.
17,938. Spring Clip Holder, B. G. Fleming and I. Crawshay, Southampton.
17,939. Apparatus for Heating Liquids, R. W. B. Sanderson, Manchester.
17,940. Harness for Draught Animals, W. Luke, Birmingham.
17,941. Bearings for Wheeled Vehicles, F. Waters, Birmingham.
17,942. Artificial Limbs, C. W. Thompson, London.
17,943. Combination Implement, H. Searle, Bradford.
17,944. Surveying Chain, T. Trussell, Nottingham.
17,945. Brake Blocks, W. Hawley, Sheffield.
17,946. Rail Joints, A. Hoffman and H. W. Falk, Sheffield.
17,947. Red Bricks, J. and J. Ryder, Manchester.
17,948. Hair Curlers, S. M. Taylor, Birmingham.
17,949. Front Steering Bicycle, T. H. Harley and C. Saer, Malton.
17,950. Safety-valves, J. Keith, Glasgow.
17,951. Folding Tables or Seats, K. J. Wörrlein, Manchester.
17,952. Valve Gear for Engines, J. E. Wallis and Wallis and Steevens, Basingstoke.
17,953. Attachment of Stirrup Leathers, J. Selmes and J. Johnson, London.
17,954. Street Watering Carts, J. Smith, Barnard Castle.
17,955. Starting Tramway Cars, J. Lyle, Glasgow.
17,956. Mail-cart, G. L. Rothschild and H. V. Baker, Birmingham.
17,957. Perambulator, &c., H. V. Baker, Birmingham.
17,958. Valves for Pneumatic Tires, G. D. R. Bunting, London.
17,959. Opening Cans, J. Chapman and T. H. Jones, London.
17,960. Pyrotechnic Compound, A. Brock, London.
17,961. Extraction of Lead with Silver, H. R. Angel, London.
17,962. Poison for Rats and Animals, C. G. Stewart, London.
17,963. Steam Boiler, J. Westray, London.
17,964. Malt Kilns, A. Kinder, London.
17,965. Distilling Alcohol, F. W. Golby.—(*J. Puypeyroux, France.*)
17,966. Steam Generators, B. Willcox.—(*La Société Universelle des Emulseurs de Vapeurs, France.*)
17,967. Obtaining Precious Metals, J. Mactear, London.
17,968. Insulators for Electric Wires, L. S. Beardsley, London.
17,969. Preventing Cotton Slipping, R. C. T. Evans, London.
17,970. Bobbins, &c. J A. Sutcliffe and G. Paley, London.
17,971 Sliver Pans, J A. Sutcliffe and G. Paley, London.
17,972. Christmas and other Cards, T. C. Dobson, London.
17,973. Cape-skirt Combination, J. P. Thornton, London.
17,974. Refining Mattes, A. J. Boult.—(*A. L. Grant and C. G. Richardson, United States.*)
17,975. Fastener or Clip for Stair Rods, W. Mycock, London.
17,976. Purifying Sugar, W. P. Thompson.—(*H. A. J. Manoury, France.*)
17,977. Door Locks, G L. Barney and J. L. Clough, London.
17,978. Chlorine Acid Potash, &c., K. J. Bayer, London.
17,979. Trap for Catching Animals, E. H. F. Hemingsley, London.
17,980. File, C. S. Steel, London.
17,981. Game, H. J. Cropper and F. K. Kendall, London.
17,982. Tin Canisters, T. Jenner and H. A. Leverett, London.
17,983. Crushing Ores, C. A. Allison.—(*T. Pilkington, United States.*)
17,984. Lights for Use in Buoys, &c., R. Whitby, London.
17,985. Dress Eyes and Loops, M. F. Kent, London.
17,986. Excavating Tools, J. Macqueen, London.
17,987. Gaseous Fuel Apparatus, S. de la G. Williams, London.
17,988. Cycle Saddles, J. A. and H. A. Lamplugh, London.
17,989. Locks of Triple-action Guns, H. D. A. Laloux, London.
17,990. Outlet Grid for Discharge Pipes, E. Kramer, London.
17,991. Horseshoes, M. Willard and J. F. Leporcq, London.
17,992. Sprocket Chains, C. E. Fanning, London.
17,993. Cycle Saddles, P. Hamonic and P. Pansard, London.
17,994. Smokeless Explosives, H. S. Maxim, London.
17,995. Preventing the Waste of Soap, L. Heymann, London.
17,996. Locomotive Boilers, A. Socher, London.
17,997. Tills, J. C. Cox, London.
17,998. Preventing Water Freezing, W. H. Power, London.
17,999. Reflectors for Sconces, L. Kilner, London.
18,000. Apparatus for Watering Mines, J. M. Greenhow, London.
18,001. Steam Engine Indicators, M. J. Wayne, London.
18,002. Attaching Articles to Chains, C. W. Barrat, London.
18,003. Obtaining Precious Metals, H. L. Sulman, London.
18 004. Horseshoes, J. Bell, Belfast.
18,005. Dampproof Cardboard Soles, J. F. C. Pereira and A. Ribeiro, London.
18,006. Machine for Cutting Metal Bars, D. M. Bull, London.
18,007. Converting Movements, &c., J. A. Wilkin, London.
18,008. Operating Tramway Switches, P. R. J. Willis.—(*C. P. Bachelder, H. E. Watjen, and W. M. Robbins, United States.*)
18,009. Wire Fences, P. R. J. Willis.—(*H. Buck, J. C. Lahman, S. S. Young, L. H. Funk, and C. H. Hawbecker, United States.*)
18,010. Implement for Stoning Fruit, J. Boeri, London.
18,011. Hammers, W. A. Wiley and H. M. Richardson, London.

*22nd September*, 1894.

18,012. Disinfecting Apparatus, F. M. Woolcock, Torquay.
18,013. Pillows for Medicinal Purposes, J. M. Hassall, Liverpool.
18,014. Brandy, Whiskey, &c., F. W. Forbes-Ross, Liverpool.
18,015. Damping Zithers, W. P. Thompson.—(*M. Andorff, Germany.*)
18,016. Felt Hats, R. Stalker, G. Baty, and J. Johnston, Manchester.
18,017. No More Burnt Food, G. C. Waterfield, Aldershot.
18,018. Time-saving Egg Poacher, G. C. Waterfield, Aldershot.
18,019. Automatic Hair Curler, J. Heys, Birmingham.
18,020. Feeding Paper to Printing Machines, J. J. Allen, Halifax.
18,021. Cycles, R. Edgar, Glasgow.
18,022. Generating Steam, G. H. Jones, London.
18,023. Attaching Cuff Links to Cards, T. Morton, Birmingham.
18,024. Woven Diving Belt, W. Terry and F. Rawnsley, Halifax.
18,025. Roller or Rink Skates, W. Heatley, London.
18,026. Manufacture of Mattresses, A. Porritt, Halifax.
18,027. Cycles, S. J. Howells, Essex.
18,028. Cupboard Catches, P. E. Ayton, Birmingham.
18,029. Machines for Fancy Stitching, F. H. Dodson, Birmingham.
18,030. Velocipede Gear Chains, J. Baylis, Birmingham.
18,031. Bi-sulphide of Carbon, G. Millard, Manchester.
18,032. Stop Motions for Spinning Machines, E. and S. Tweedale, and J. Smalley, Manchester.
18,033. Tobacco Pipes, P. C. Jones, Guildford.
18,034. A New Advertising Medium, C. Goater, London.
18,035. Thread-cutting Apparatus, J. A. and T. A. Crawford, Newcastle-on-Tyne.

18,086. Cyclometers, R. O. Brown and C. H. Murray, Newcastle-on-Tyne.
18 037. Closing the Placquet Hole of Ladies' Dresses, E. J. Wildish, Essex.
18,038. Window Opener, L. L. J. Duncan, Lymington.
18,039. Convertible Cot, F. T. Edgecombe, Glasgow.
18,040 Drain Connections, B. R. Phillipson, Dublin.
18,041. Device for Cutting Tubes, F. J. Burrell, Thetford.
18,042. Cycle Saddle Covers, E. K. Mason, Birmingham.
18,043 Lowering Window Sashes, W. Davies, Birmingham.
18,044. Cheques, &c., W Webber, Plymouth.
18,045. Stoves, S. Watkins.—(*E. R Cahoone, United States.*)
18,046. Looms for Weaving Wire Cloth, W. Begg, Glasgow.
18,047. Gasholders, J. Dempster, Manchester.
18,048 Cycle Link Gear, W. Askham and W. Earp, Nottingham.
18,049. Atmospheric Gas Burners, D. McC. Gibb, Glasgow.
18 050. Anti-kicking Strap, T. E P. Gardner, London.
18,051. Pipe Cleaner, W. H. Boyles and A. J. Curnow, London.
18,052. Valve Apparatus for Sewers, T. H. Baker, London
18,053. Drainer for Laundries, W. C. Collins, Birmingham.
18,054 Hot-water Cylinders, A. E. Hodgson, Halifax.
18,055. Fishing Rods, S. Allcock and E Perks, Birmingham.
18 056. Fastening Cravats or Neckties, J. Hey, London
18,057. Arc Lamp Carbon Regulator, L. Zausmer, London.
18,058. Bed-pan, F. J. Mockler, London.
18,059. High-pressure Water Cock, C. Schmidt, London.
18,060. Device for Warming Beds, &c , F. Taylor, London.
18 061. Toy, W Ditchburn, London.
18 062. Ladies' Veiling, A. A Smith, London.
18 063. Belt Pulleys, W. O. Wood and C. Burnett, London.
18 064. Urinals, C. O. Haas, London.
18 055. Turning Over Music Leaves, E. A. Brown, Keighley.
18 066. Postal Letter Cards, &c., W. H. Harris, London.
18,067. Shoe Lace Gripper, J. Dartnall and H. Dartnall, London.
18,068. Cycle Driving Gear, G. F. and J. W. Bint, London.
18 069. Pneumatic Tires, J. L. Wiles, London
18.070. Obtainment of Precious Metals, J. Mactear, London.
18,071. Vice, H. Schwarz. London.
18,072 Washing Dolly Supports, A. S. Anderson and W. Patterson, Newcastle-on-Tyne.
18,073 Paper Fasteners, S. H. Crocker, London.
18,074. Bottle Labelling Machines, W. Fletcher, London.
18,075. Bottle Labelling Machines, W. Fletcher, London.
18,076. Pocket Books and Card Cases, W. Fletcher, London.
18 077. Colouring Matters, F. Anselm and the Clayton Aniline Company, London.
18,078. Gas Enriching Apparatus, P. Dvorkovitz, London.
18,079. Showing the Rate at which a Cycle is Travelling, J. Flynn, London.
18,030. An Improved Toy, W. G. B. Sweet, London.
18,081. Making Gelatine Pearls, &c., H. Nègre, London.
18,082. Pneumatic Valve, J. Winfield and H. Wilkinson, London.
18,083. Stages for Theatrical Performances, I. Kiralfy, London.

*24th September*, 1894.

18,084. Push buttons for Gloves, &c., J. G. Paterson, London.
18,085. Skin Ointment, A. Jamieson, Glasgow.
18,086. Lifts or Hoists, W. Terry and F. Rawnsley, Halifax.
18,087. Lamps for Velocipedes, G. W. Möhrstädt, Birmingham.
18,088. Spring Tire, P. J. Vetter, London.
18,089. Pin for Fastening Dresses, F. H. Weight, Birmingham.
18,099. Cycle Saddles, J. B. Brooks, Birmingham.
18,091. Purifying Coal, R. Clough, M. L. Mulholland, and R. Clough, jun., Stockton-on-Tees.
18,092. Protectors for Water Gauges, A. Dobson, Belfast.
18,093. Circular Saw Benches, T. N. Robinson, Manchester.
18,094. End Rails, W. Whiting and H. B. Tucker, Bath.
18,095. Tug Stops for Harness, W. Crudgington, Birmingham.
18,096. Steam Generators, G. V. Priestley, Leeds.
18,097. Stopper or Presser for Pipes, G. T. Neville, Birmingham.
18,098. Holding Sticks, J. J. Malone and J. N. Greensill, Birmingham.
18.099. Polishing Mops, T. H. Pearce and C. Taylor, Birmingham.
18,100. Casting Cable Chains, J. F. Hall, Sheffield.
18,101. Tire Covers, J. Moseley and B. Blundstone, Manchester.
18,102. Bedsteads, E. Woods, Liverpool.
18,103. Stretching Fabrics, J. Westley and A. J. Cunliffe, Manchester.
18,104. Ball Valves for Cisterns, W. Bevis, London.
18,105. Safety Window, C. Reid, Aberdeen.
18,106. Pocket Knives, O. Olson, Newcastle-on-Tyne.
18,107. Fastener for Railway Rails, W. Nicholson, London.
18,108. Dust Collector, H. Richter, Berlin.
18,109. Webbing for Pneumatic Tires, G. Hiller, Berlin.
18,110. Lawn Mowers, W. H. Luther and J. Cockburn, Glasgow.
18,111. Gang Needle Sewing Machines, L. H. Smith, Glasgow.
18,112. Air Compressors, W. B. Crichton, Bradford.
18,113. Copper Whiskey Measure, H. Rendell, Dublin.
18,114. Wheeled or Roller Skates, C. B. Crisp, London.
18,115 Combined Fireguard and Toaster, G. Brendon, Stratton.
18,116. Clips, H. W. Herbst, London.
18,117. Jointing Soft Metal Pipes, F. Garon, sen., Southend.
18,118. Seamless Steel Tubes, R. Wootton, Birmingham.
18,119. Worms for Conveyor Troughs, T. Taylor, London.
18,120. Oil Lighting, A. J. Riley and L. Whitehead, London.
18,121. Stopping Leaks in Boats, G. A. F. Wilson, London.
18,122. Cycle Driving Gear, P. Malicet and E. Blin, London.
18,123. Gearing for Cycles, A. E. Hodder, London.
18,124. Military Tents and Poles, A. S. Tomkins, London.
18,125. Drying Apparatus for Boots, &c., A. Bodde, London.
18,126. Jointing Stoneware Pipes, &c., J. Hall, London.
18,127. Lighting Household Fires, S. A. Johnson, London.
18,128. Time Register, F. G. M. Wetherfield.—(*C. K. Jardine, British Guiana.*)
18,129. Fastening Lids of Bottles, C. E. H. Greiner, London.
18,130. Rotary Engines, A. F. S. van de Laar, London.
18,131. Making-up Columns of Type, G. Eastwood, London.
18 132. Disintegrator and Pulveriser, S. Croasdell, London.
18,133. Sterilising Milk, E Edwards.—(*R. Lüders, Germany*.)
18,134. Baskets, E. Edwards.—(*E. Roesler, Germany.*)
18,135. Fastenings for Garments, E. Edwards.—(*The Sisters Hoffmann, Germany*.)
18,136. Confining Pens for Poultry, &c , J. M. Robb, London.
18,137. Studs Puzzle, J. B. Young, London.
18,138. Printing Machinery, &c , R. C. Annand, London.
18,139. Connecting Leather, G. F. Redfern.—(*H. C. Gros, Germany.*)
18,140. Toasting Forks, C. W. Durnford, London.
18,141. Address Labels, J. H. Bates, London.
18,142. Obtaining Infusions of Tea, W. Eisenmenger, London.
18,143. Pasteurising Apparatus for Milk, W. Paasch, London.
18,144. Drain Traps and Chambers, G. and F. Couzens, London.
18,145. Incandescent Gas Burners, F. Fischer, London.
18,146. Recovery of Metals from Ores, H. L. Sulman, London.
18,147. Venetian Blinds, M Boate, Liverpool.
18,148. Iron Bedsteads, T. Hilton. Manchester.
18,149. Postal Transmitters, I. Cizek and L. Maizner, London.

*25th September*, 1894.

18 150 Mackintoshes, P. H. Davy, London.
18 151. Extraction of Gold from Ore, F. C. May, London.
18,152 Bicycles, J. Harrison and J. Dodd, Nottingham.
18 153. Electricity Meters. J. Perry, London.
18 154 The Rule of Ten, F. Harrop and W. H. Boyles, London.
18,155. Iron, J. Green, Liverpool.
18,156. Manufacture of Nitro-cellulose, G. H. Hosie, Glasgow.

18,216. Hooks for Eye-glass Guards, H. A. Deraismes, London.
18,217. Transmitting Telephonic Messages, L. I. Blake, London.
18,218. Printing on Textile Fabrics, J. Bolet, London.
18,219. Propellers, W. E. Sanger, London.
18.220. Ventilating Brick, R. W. Ray, London.
18,221. Thermo-static Lubricator, A. Bergtheil, London.
18,222. Rotary Knife-cleaning Machines, J. W. Sutton, London.
18,223. Stud, M. Veit, London.
18 224. Hair-pin, J. W. Slater, London.
18,225 Dredging Apparatus, H. H. Leigh.—(*The Mining and Dredging Power Company, United States*.)
18,226. Heat Interchanger, W. Garden, London.

*26th September*, 1894.

18,227. Hinged Joint, R. J. Beale, London.
18,228. Radiators for Refrigerating Pipes, L. Sterne, London.
18,229. Tiles, J. N. Peake, Longport.
18,230. Wheel, R. Palmer, Manchester.
18,231. Making Leather Belts, G. E. Stead, Manchester.
18,232 Wheel-cutting Machines, C. and G B. Taylor, Birmingham.
18,233. Pavements, J. T. Pearson, Burnley.
18.234. Moulding India-rubber, H. B. and W. F. Bourne, London.
18.235. Picker for Looms. J. Taylor, Belfast.
18,236. Can Opener, W. E Morgan and G. E. May, Southampton.
18,237. Gas Generator, G. Threlfall and R. J. Hodges, London.
18,238. Balconies of Houses, H. T. G. Wybrow, Birmingham.
18,239. Portiere Rods, J. Harris, Birmingham.
18,240. Vehicles for Perishable Goods, J. E. Callow, Bristol.
18.241. Limestone Furnaces and Kilns, W. Deighton, Knaresborough.
18,242 Cased Tubings, C. Harvey, Birmingham.
18,243. Peptonised Bread, Peptine Maltine, Ld., and G. Bartlett, Leicester.
18,244 Tires for Cycles and Vehicles, W. Stevenson, Nottingham.
18.245 Protecting Watches and Articles, B. Barden, Dublin
18 246. Bosses for Picking Shafts, J. Taylor and B. Kay, Halifax.
18,247. Tubular Steam Generators, W. Scott, Newcastle-on-Tyne.
18.248. Hydrocarbon Oils, C. E. Parker-Rhodes and S. F. St Jermain Steadman, London.
18 249. Washing or Scouring Fabrics, J. Read, London.
18,250. Invoice and Memorandum Forms, R. Raynham, London.
18,251. Sanitary Pipes, W. Ingham and B. Langton, Leeds.
18,252. Frame for Shaving Toilet, T. F. Senior, Sheffield.
18.253. Propelling and Steering Vessels, J. Jopling, Sunderland.
18.254. Mashing and Extracting Machine, T. Cleminson. Liverpool.
18.255. Lavatories or Washhand Basins, J. Craig, Manchester.
18,256. Spun Glass, J. L. Wittwe, Bohemia.
18,257. Cigars, P. C. Sarapata and P. Souvazoglu, Manchester.
18,258. Printing upon Calico, E. Potter and Co., Ld., and J. Barr, Manchester.

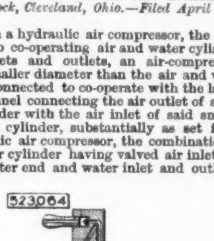
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**523,064.** Compound Hydraulic Air Compressor, *W. A. Babcock, Cleveland, Ohio.—Filed April 26th,* 1893.

*Claim.*—(1) In a hydraulic air compressor, the combination of two co-operating air and water cylinders having air inlets and outlets, an air-compressing cylinder of a smaller diameter than the air and water cylinders and connected to co-operate with the latter, and an air channel connecting the air outlet of an air and water cylinder with the air inlet of said smaller air-compressing cylinder, substantially as set forth. (2) In a hydraulic air compressor, the combination of an air and water cylinder having valved air inlet and outlet at its outer end and water inlet and outlet at its inner end, an air and water cylinder arranged in axial alignment with said other cylinder and having air inlet and outlet at its outer end and water inlet and outlet at its inner end, valve mechanism controlling the water inlets and outlets, an air cylinder of smaller diameter than the two cylinders and arranged in axial alignment with the same, and having valved air inlet and outlet at its outer end, connected pistons in the cylinders, and an air channel connecting the air outlet of the first air and water cylinder to the air inlet of the air cylinder, substantially as set forth.

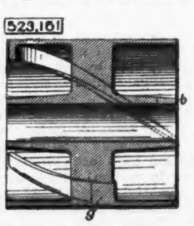
523064



**523,161.** Means for Ventilating Armatures, *T. C. Coykendall, Rondout, N.Y.—Filed October 17th,* 1893.

*Claim.*—(1) The combination with a dynamo-electric machine or motor, of a pulley having a hub *b*, radial arms *g*, air passages between the radial arms, and fan blades mounted upon the pulley between the radial arms, substantially as described. (2) The combination with a dynamo-electric machine or motor, of a pulley carrying fans consisting of blades extending spirally around the axis thereof, having one edge radial to the axis of the pulley shaft and the opposite edge inclined to such radius, the blades having a gradual inclination from the radial edge to the inclined edge, substantially as described.

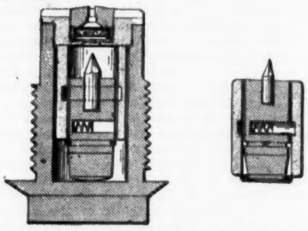
523,161



**523,110.** Percussion Fuse for Projectiles, *W. J. Dungan, Philadelphia, Pa.—Filed April 4th,* 1894.

*Claim.*—(1) The herein-described igniter plunger for percussion fuses for projectiles, consisting of a pointed spindle having an annular groove, in combination with an open ring spring seated in said groove, and a sleeve fitted on said spindle and projecting beyond its point and adapted to dislodge the ring from its seat, when the projectile is fired, as and for the purpose set forth. (2) In a percussion fuse for projectiles a pointed grooved spindle having a radial spring locking bolt, in combination with an open wire ring encircling said spindle and seated in the groove, and a sleeve with an annular interior recess fitted on the spindle in advance of the ring and extending beyond the point of the spindle, as and for the purpose set forth.

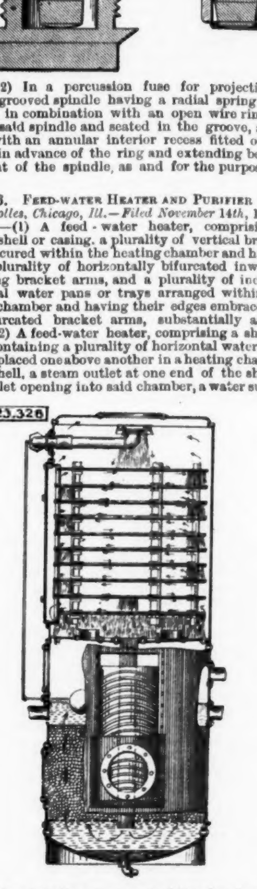
523,110



**523,326.** Feed-water Heater and Purifier *E. G. T. Colles, Chicago, Ill.—Filed November 14th,* 1893.

*Claim.*—(1) A feed-water heater, comprising a vertical shell or casing, a plurality of vertical bracket pieces secured within the heating chamber and having each a plurality of horizontally bifurcated inwardly extending bracket arms, and a plurality of inclined horizontal water pans or trays arranged within the heating chamber and having their edges embraced by the bifurcated bracket arms, substantially as set forth. (2) A feed-water heater, comprising a shell or casing containing a plurality of horizontal water pans or trays placed one above another in a heating chamber in said shell, a steam outlet at one end of the shell, a steam inlet opening into said chamber, a water supply pipe opening into the upper part of the chamber and provided with a discharge, and a downwardly and outwardly flared guard or shield interposed between the steam outlet and the water supply discharge, substantially as set forth. (3) In a feed-water heater and purifier, having a steam inlet and outlet, comprising a shell or casing, a plurality of vertical bracket pieces secured within a heating chamber in said shell, a plurality of water pans arranged within said heating chamber and supported by said bracket pieces, each of said pans being of less diameter than the said chamber, and each pan being cut away marginally to form a discharge opening, all substantially as set forth and described.

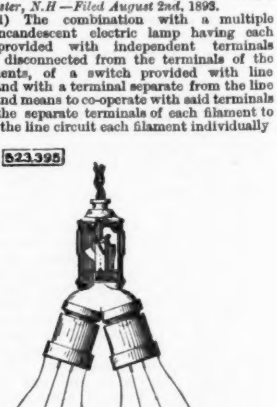
523,326



**523,395.** Multiple Filament Lamp, *A. L. Clough, Manchester, N.H.—Filed August 2nd,* 1893.

*Claim.*—(1) The combination with a multiple filament incandescent electric lamp having each filament provided with independent terminals electrically disconnected from the terminals of the other filaments, of a switch provided with line terminals and with a terminal separate from the line terminals, and means to co-operate with said terminals and with the separate terminals of each filament to connect in the line circuit each filament individually and also the said filaments collectively in series and in multiple, substantially as described. (2) In a multiple filament incandescent electric lamp, the combination with a base provided with a plurality of terminals, and a plurality of filament containing globes or bulbs attached to the said base, and each provided with separate terminals for its filament co-operating with corresponding terminals on the said base, and a single switch connected to the terminals of the said base and constructed to connect the said filaments in circuit in series, and in multiple, and also to connect the terminals of each filament in circuit independent of each other substantially as described.

523,395



## THE ENLARGEMENT OF LIVERPOOL STREET STATION, GREAT EASTERN RAILWAY.

### No. IV.

*Parcels Office.*—It is due to the fact that the terminus of the Great Eastern Railway is on the low level that the "Parcels Office," which we now proceed to describe and illustrate, appears, when viewed from the platforms of the station, to be upstairs, or on the first floor, whereas the entrance to it from Bishopsgate-street is readily effected by means of a pair of inclines, one for ingress and the other for egress, of easy gradient, shown in the "General Plan of Parcels Office" in Fig. 1, at C C, D D, and in elevation in Figs. 4 and 5. There is an incline in Liverpool-street, near its junction with Bishopsgate-street down to the entrance gates of the terminus of the Great Eastern Railway.

*General plan.*—The general plan in Fig. 1 represents, therefore, what may be called the ground floor of the Parcels Office, which consists of a pair of central spans of 30ft. each, a pair of covered approaches also of 30ft., situated on each side of the main portion of the building, and forming a continuation of the inclines from Bishopsgate-street, and a pair of wings or returns of the same span of 30ft. These dimensions are all measured in the direction of the lines of track—that is, in the direction of A A in Fig. 1. At the broad end of the office, the central spans are connected with the foot-bridge over part of the existing station by a fantail-shaped covered gallery. At the junction of the gallery or passage with the bridge at E E, there is another foot-bridge at right angles to the former, shown in section and elevation in Figs. 6 and 7. Longitudinally the bays or spans are situated between the cast iron columns, which form the two central spans, are double and spaced 5ft. apart from centres. These bays vary in width from 42ft. 3½in. to 51ft. 5½in. and 51ft. 11¼in. at the respective ends of the building. The inclined approaches already referred to are carried under arches which pierce the wedge-shaped site of the shops on the level of the street, shown in the Key Plan in our columns for June last, and thus form two gaps or breaks in the long line of shop frontage, above which are the offices of the company, constituting the real façade of the extension in Bishopsgate-street.

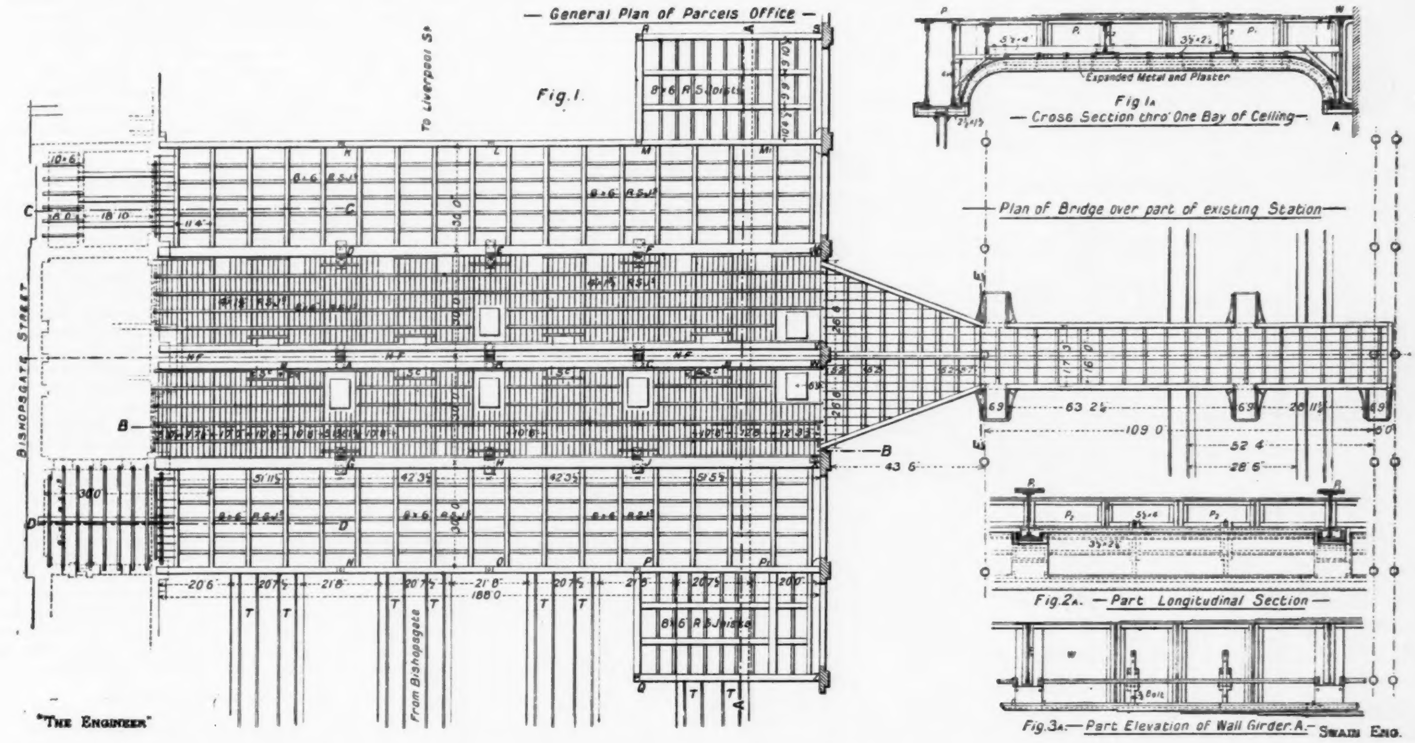


Fig 1A — Cross Section thro' One Bay of Ceiling —

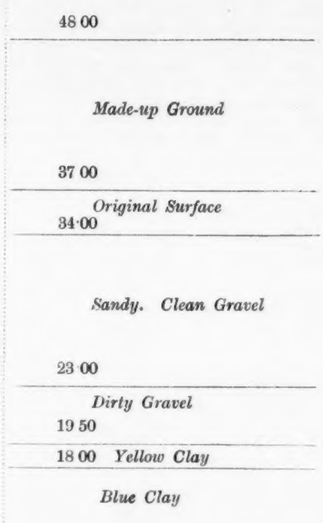
Fig. 2A. — Part Longitudinal Section —

Fig. 3A. — Part Elevation of Wall Girder A. —

*General design.*—From the general plan in Fig. 1, cross-section in Fig. 2, and longitudinal section in Fig. 3, the construction is as follows: Upon cast iron columns, double and single, are carried heavy wrought iron plate girders, unquestionably the best type to adopt for the support of a building, the maximum load upon which in actual practice is almost an unknown quantity, and one in which a very small crack or thread, in any of the arches or walls, might be a very serious matter. Anyone who has designed a warehouse for the storage of grain, especially if kept in a loose condition, that is, in bulk, has a very fair idea of the amount of the weight it is possible to pile up on the floor. Into the longitudinal plate girders are framed the cross girders, also of the plate type. Upon them rest rolled steel joists, 8in. by 5in., and weighing 31 lb. per foot run, and to them are riveted smaller steel joists or trimmers, 4in. by 1¾in., at 8½ lb. to the foot. We may now pass on to the details of the construction.

*Foundations.*—The strata passed through before arriving at the blue clay were composed first of made-up ground consisting of the usual miscellaneous description found under similar circumstances in similar localities, then a layer of earth, or the original surface of the ground. Underneath this there is a stratum of clean gravel, succeeded in downward progression by a bed of a somewhat dirtier description of the same material. A substratum of yellow clay underlies the gravel, and in its turn overlies the blue clay. In Fig. B the approximate respective depths and thicknesses of the different strata are shown, and are readily ascertainable from the levels given at each change in their composition. All the columns and heavier parts of the whole widening of the station were founded at the maximum depth, reaching down to the blue clay; but some of the walls and lighter portions of the buildings found a solid and secure resting place upon the gravel. Had this substratum been of a more rocky or harder character, and had it contained a smaller proportion of sand in it, a less depth might possibly have sufficed for some other parts of the structure.

Fig. B



*Cross section.*—A cross section of the Parcels Office along the line A A—in Fig. 1—is represented in Fig. 2, from which it will be perceived that the building itself consists of the two spans already mentioned, contained within its two side walls, and that both the ground and first-floor are intended to carry loads of the maximum amount. It is no doubt for this reason that the cross plate girders carrying these loads derive no support from—that is, do not rest in any degree upon the side walls, but upon cast iron stanchions, as seen in the cross section in Fig. 2. Above the first floor, where the weights to be provided for are comparatively of a small amount, the floor girders and joists are supported in the usual manner by the walls of the building. Both the side approaches and wings or returns are roofed in and protected by a parapet plate girder, shown at P P, in Figs. 2, 4, and 5. In order to carry the mains of the Gas Lighting and Coke Company across the site of the widening, it was necessary to build a subway for them, shown under one of the approaches in Fig. 2, which ran from the existing station to Bishopsgate-street, at a depth of 6ft. below that of the foundations for the rest of the work. In Fig. 8 is a part longitudinal section of the subway under the track and the platforms respectively, and Figs. 11 and 12 show the corresponding cross sections at A B and C D. In Fig. 12, which is a cross section under the rail level, the arch of the subway, which is 11½in. in thickness, when underneath the platforms, as in Fig. 11, is replaced by rolled joists 1ft. 6in. deep, and small jack arches 9in. in depth of brick, as shown also in Fig. 8. The invert has the same thickness as the arch, and is set on a bed of concrete 2ft. thick and 18ft. wide over all, including the side walls, which are each 3ft. in thickness. A vertical section in Fig. 9 shows the intake or connection between the subway and the gas mains, which are 4ft. in diameter, laid in duplicate, 18in. apart, and connected together as in Figs. 9 and 10. An enlarged plan of the iron grating, 12ft. by 6ft., is shown in Fig. 13.

Fig 8.

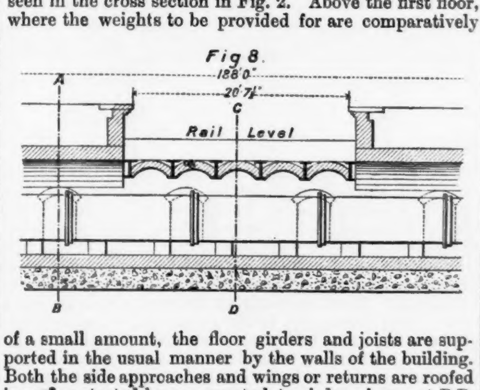


Fig 9.

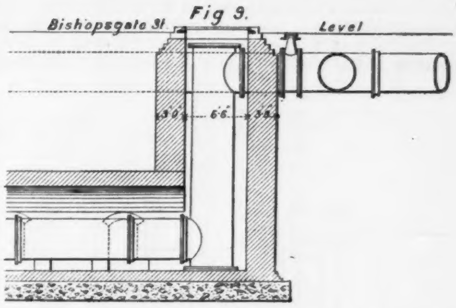

*Concrete, mortar, and bricks.*—A bed of concrete 10ft. by 10ft. by 2ft., surmounted by four tiers of brick footings, upon which is placed the bedstone 5ft. square and 2ft. thick, forms the foundation for the single columns supporting in Fig. 2 the main girders belonging to the two side approaches and their returns. According to the nature and situation of the work, so does the composition of the concrete slightly vary. In the foundations generally it consists of one

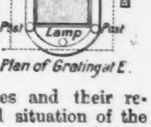
Section at C.D.

Fig 13.



Plan of Grating at E.

part of Portland cement to six or seven parts of mixed gravel and sand, but in "bad spots" the proportion of cement is increased. Three descriptions of mortar have been used on the works:—(1) Lime mortar composed of one part of blue lias lime and two parts of sharp clean sand. (2) Cement mortar of the same proportions, substituting Portland cement for the blue lias lime. (3) Black mortar in which the ingredients are, one part of sand, one of ashes, and one of lime. This last description of mortar was largely used in the construction of the heavy retaining wall reaching from the station extension to the bridge at Skinner-street, which we shall hereafter describe and illustrate. The wall was built of old bricks obtained from the demolition of houses, walls, sewers, and other ancient structural relics, during the clearing of the site, and the wall was faced with Brindle's bricks, which are of a dark colour. It was also coped with bull-nosed 14in. B B Staffordshire blue bricks, and so the colour of the mortar was made to match. All the bedstones are of the well-known Darley Dale stone.

"The Engineer"

Strain Eng.

*General construction.*—Of these single columns the two exterior of the returns or wings marked C C in Fig. 2 have a diameter of 18in. and a thickness of metal of 1¼in., while those lettered $C_1$ $C_1$ are increased to 2ft. in diameter, as they have a heavier load to carry. A reference to Figs. 2 and 3 will serve to indicate the general construction of the Parcels Office, the first floor of which stands upon twin cast iron columns, and the second floor on vertical centre and side stanchions of a particular section. These double columns rest upon bedstones having a superficial area in feet of 12 by 10 and a thickness of 1ft. 9in. Five footing courses of brickwork, with a total height of 3ft., transfer the weight of the superstructure to a solid mass of concrete 21ft. by 19ft. and 3ft. thick. For the footings in foundations, in the body or the backing of walls, ordinary stock bricks are used, but the description employed for the facing varies in different parts of the works. Thus, the walls of the Parcels Office are faced for a height of about 4ft. 6in. from the level of the side approaches with Staffordshire blue bricks, and above that level with Leicester bricks. Again, the two new side walls of the extension are built of stocks, faced for a height of 7ft. above the level of the platform with Ruabon bricks, and above that with Suffolk bricks. Ruabon bricks are also used for the rounded corners in the general offices fronting Bishopsgate-street. Suffolk bricks form the facing of that portion of the new buildings, relieved by ornamental stone dressings from the quarries of Portland, Monkspark, and Bosgrove. While generally all the work above ground is set in lime mortar, the bedstones are laid in cement, and in all cases where new walls have been joined on to old ones, cement mortar is used to bond them together with.

*Double columns and stanchions.*—An elevation of the double cast iron columns and vertical stanchions running down the centre of the building in Figs. 1, 2, and 3 is represented to a larger scale in Fig. 14. From base to capital the columns, which are 5ft. apart from centre to centre, are 9ft. 11½in. in length, or measured from top of the bedstone, 11ft. 5½in., have an external diameter of 2ft. and a thickness of metal of 3in. At the lower extremity each column is widened out so as to form a flange having a diameter of 2ft., and a thickness of 3¼in., and bolted down to the bed or base plate by twelve bolts spaced 12in. apart and of a diameter of 1⅜in.—Fig. 16. These base plates are of cast iron and oval in shape, with conjugate diameters of 7ft. and 5ft. respectively, as in Fig. 15. In Fig. 17 there is an enlarged plan and section of the base plates, which are 1ft. 6in. in total height, have a thickness of top flange of 3¼in., equal to that of the lower flange of the columns to which they are bolted, a thickness in the body of 3in., while in the lower flange the same dimension tapers from 3in. to 2½in. at the circumference, which has a rib or fillet 6½in. deep throughout. Six lewis bolts —Figs. 15 and 17—1¼in. in diameter and 1ft. 2in. long, hold down the base plate of each column to the concrete foundation, and are screwed home by a nut and washer 5in. in diameter and ⅝in. thick. Cast iron struts of the form and dimensions shown in Figs. 14—19 are used to brace the twin columns together in the figure of a couple of St. Andrew crosses, and are 8in. wide at the centre, 5½in. at the ends, and 1¼in. in uniform thickness. These braces are bolted to the columns by two bolts 1⅜in. in diameter and two of 1in. in diameter, spaced 7in. and 9in. apart, and where the attachment occurs the columns are thickened out from 3in. to 5¼in.—Figs. 17—19. The capitals of the double columns, which have a space of 2ft. 2in. between them, are surmounted and connected by a "table girder" of cast iron 3ft. 6in. in total depth —shown in elevation on Fig. 14, and in plan and section in Figs. 20 and 21. It is 8ft. in total length, 2ft. 10in. in width, and 3in. in thickness in the centre rib or web, and in both the upper and lower flanges, which are of very different forms—Fig. 21. The former is a simple horizontal flange, but the latter is provided with two vertical or side plates, as they would be called in girders of wrought iron, which have a depth of 1ft. 8in. and a thickness of 3in. at their junction with the horizontal portion of the flange, tapering at the open ends to 2in. Four bolts 1½in. in diameter connect the table girder with the capitals of the columns. Upon the vertical stanchions —Fig. 14—23ft. 3½in. in total height, is carried the second floor of the building. They have a plain base and capital, or, rather, an upper and lower flange, measuring 3ft. by 2ft. 10in., by 3½in. in thickness, and are 2ft. in outside dimensions on all four faces, as shown in cross-section in Fig. 22. The principal or centre rib is 2½in. thick, the two interior and two exterior ribs 2in. at the broader end, tapering to 1¾in. at the extremities. For a length of 10ft. of the upper part of the stanchions, two ribs or projecting fillets are cast 2½in. in depth and 7in. apart from inside edges. The stanchions are bolted to the upper flange of the table girder by four bolts 1⅜in. in diameter. It should be mentioned that all the flanges of the cast iron girder work, columns, stanchions, and in every instance in which two separate parts are bolted together, the surfaces are all accurately and truly planed, so as to ensure a uniform and even bearing area. In the erection of large workshops for the numerous branches of mechanical engineering, the advantages of employing twin columns has been long recognised. Strength, compactness, simplicity, durability, large bearing surface, and comparative cheapness, are among their principal characteristics. When several shops are erected parallel to one another, with or without partitions, the double columns can be connected by girders, as in the building under notice, which can further be made to act as rail bearers, or, in fact, as rails themselves, upon which gantries can run to hoist and shift whatever may be required in the shops below. All these operations can be carried on without in any way interfering with the single columns which support the roof principals.

## GERMAN EXHIBITS AT THE ANTWERP INTERNATIONAL EXHIBITION.

(*From our Special Commissioner.*)

Probably the largest makers of wire rope and electric cables on the Continent are Messrs. Felten and Guilleaume, of Mülheim. At Antwerp their exhibit of all classes of wire rope is not only larger than that of any other firm, but is one of the most important installations in the German section. Commencing with various gauges of iron and steel wire, plain and galvanised, they next show different sorts of copper and brass wire, including some specimens of high conductivity for telephones. Besides these, they exhibit two descriptions of a special make of wire. One of them, which they call "compound," consists of a core of steel and an outer covering of copper or brass. By this means a wire is obtained possessing the elasticity and tensile strength of steel with the conductivity of copper. The other special wire is made in the same manner, but of two different classes of bronze. The inner part consists of a wire capable of standing a great breaking strain, and this is covered with a metal of high conductivity. As there is very little difference in the composition of the metal in the two sorts of bronze, they are affected in the same manner by variations of temperature, and the result of this method of manufacture is a wire with qualities possessed by no homogenous wire of any description. The exhibitors say that it is more particularly noticeable for its extreme flexibility. Tests are given of the conductivity, elongation and breaking strain of the copper and brass wire which are exhibited. The breaking strain of the steel wires is also given; one of these, made of crucible steel, is stated to have supported a strain of 185 tons to the square inch. They also show some very fine brass and steel wire looking like silk. This is used chiefly for sewing silk neckties, and for making up fancy work.

As this firm started the manufacture of galvanised iron wire in 1853, and had then for many years been engaged in making wire rope, they are able—from their own products—to show the changes and developments which

Swain Eng

have taken place in all classes of wire cables. In those made of galvanised wire for shipping, &c., very thick wire was used in the earlier ones, and gradually finer in cables of more recent date. The same may be said of mining cables, of which—both round and flat—a good historical collection is shown. But the most interesting part of Messrs. Felten and Guilleaume's exhibit consists in their electric appliances. Commencing with single wires coated with india-rubber or gutta-percha, and not otherwise protected, they show how wires have been grouped; how steel wire has succeeded iron for sheathing, and how special preparations of caoutchouc—such as okonite, kerite, &c.—have been introduced as insulators. Their latest improvements consist in insulating by means of prepared paper, and using wire of Z section for sheathing. Fig. 1 shows two wires with a flat strip of paper between them, twisted together and then covered by a band of paper. In Fig. 2 the strip of paper is in the form of a cross; it serves to separate four wires, which are twisted and covered as in Fig. 1. These groups of wire are then made up into a cable, and covered with lead or other protecting material as may be desired. Besides lightness and cheapness, the use of paper has other advantages. The small quantity of air which is necessarily enclosed when the paper is twisted, helps to insulate and increases the conductivity of the wire; and by the use of different coloured paper, it is easier when making joints or repairs to distinguish to which circuit a wire belongs. Telephone cables of this description have recently been put down in Rome, Munich, and St. Petersburg. The Z-shaped wire was first introduced for wire rope tramways, but it is now used for other purposes. Figs. 3 and 4 show a submarine long-distance telephone cable. The group of four wires, insulated by paper, as described above, is enclosed in a leather sheath, and then covered with two layers of gutta-percha. Round this an asphalted ribbon is wound, and then the Z-shaped wire. As in this, each strips interlocks with the next one, an incompressible and impenetrable covering is formed. Finally it is covered with a water-tight composition. When using cables made with this special form of wire for aërial tramways, it will be seen that more than half of the outer covering must be worn away before one strand of the wire can become displaced.

FIG. 1.

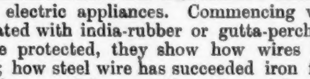

FIG. 2.

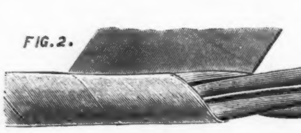

FIG 3

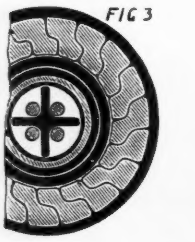

FIG. 4.

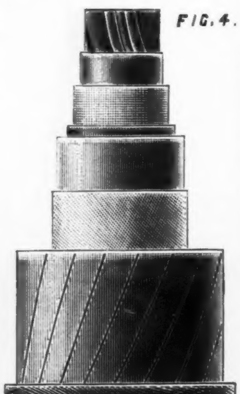
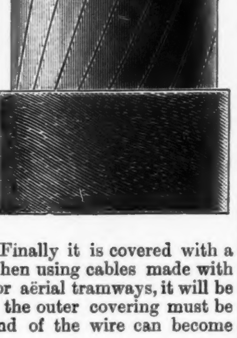


One of the latest cables made by this firm is shown on Fig. 5. It is for the telegraph from Goeschenen to Airolo, through the St. Gothard tunnel. It was put in place in October, 1893, to replace one by the same makers laid in 1882. As it has been found in the working of the tunnel that the sulphuretted hydrogen, sulphuric acid and ammonia, contained in the water which exudes from the walls of the tunnel, have affected the rails and sleepers, it was necessary to take special precautions. The cable is formed of seven groups of seven copper wires, each $\frac{1}{36}$in. in diameter, insulated by alternate layers of Chatterton's composition and gutta-percha till the diameter of the conductor was $\frac{1}{4}$in. Round this, impregnated ribbon was wound, and the seven conductors were then coiled, and covered with tarred ribbon. This was surrounded by a double sheath of lead, covered with an insulating composition, on which twenty-five strands of the special wire were wound, dovetailing into one another as shown on the drawing. A layer of a special composition outside this wire completed the cable, which when finished had a diameter of 2$\frac{3}{64}$in. The total length was ten miles, and it was supplied in half-mile sections, each section weighing approximately fifteen tons.

FIG. 5.



Another part of this exhibit consists of junction boxes. Small boxes are shown for the union of two or three cables, with joints made either by interlacing and soldering the wires, or by connecting them with two strips of copper held by set-screws. Besides these, there are two large distribution boxes, one for the three-wire, and the other for the two-wire system. They are in cast iron frames on brick foundations, and are provided with manholes and covers. The three-wire box is divided into eight chambers, for the reception of twenty-four cables, of which three are feeders, and twenty-one distributors.

There are several other exhibits at this stand showing different applications of wire, such as door-mats made of galvanised steel wire rolled spirally, and engine packing, formed of bundles of very fine iron or brass wire plaited together.

Another large German exhibit is that of the Phœnix Company of Laar. This firm show steel tram rails of every section used, as well as angle, T, Z, and many irregular sections of rolled steel. They also have bottles for containing liquid carbonic acid, and other liquefied gases, in all stages of manufacture. One steel bottle, which is intended for liquid hydrogen, is 8in. diameter, 4ft. 7in. long. It holds eight gallons, and has been tested to 4400 lb. on the square inch. Its weight empty, including valve and cover, is about a hundredweight. Besides these, they exhibit wheels, steel shells, and some hardened steel balls for mills.

The Mannesmann Tube Works of Düsseldorf have also a collection of steel bottles for liquid carbonic acid, oxygen, hydrogen, &c. The liquefied gas in these, exerts a pressure of about 1000 lb. to the square inch; but the bottles are all tested to 3700 lb., and are usually capable of standing a pressure of 7400 lb. before bursting. One of these bottles is exhibited which was filled with carbonic acid, and allowed to fall across a steel rail from the height of 23ft.: it is only slightly dented. Another speciality of this firm is the manufacture of drawn steel tube telegraph poles, One of those exhibited is 36ft. long, in one piece. Poles of this description are usually made with several offsets, and taper gradually to a point; for the sake of appearance the offsets are hidden by ornamental cast iron rings. Several special descriptions of steel tubes form part of this exhibit. Amongst them are boiler and refrigerator tubes, hardened tubes for soundings, and polished steel tubes for the frames of bicycles. They also show different sizes of steel shells.

A very fine display of copper pipes, bends, &c., is made by the Elmore's Metal Company, of Cologne. The largest piece is a pipe 17ft. long, 15in. external diameter, $\frac{1}{2}$in. metal. They also show examples of the application of the Elmore process in covering worn iron hydraulic press pistons, pump plungers, and other similar pieces with copper.

German machinery has mostly been kept in its proper place—the Machinery Hall; but there are two exhibits of machinery in the main building worth noticing. The first is that of Messrs Huck and Co., of Bielefeld. They manufacture various descriptions of lifting and traversing jacks, differential and other pulleys. One peculiarity in their lifting jacks is a safety brake, by which the pressure can be taken off immediately, or the object which has been lifted can be lowered at any desired speed. The lifting handle turns a small ratchet wheel on the outside of the machine; this wheel is hollow, and contains a strong spiral spring which presses against its inner circumference, whilst one end of it is solidly fixed to the main shaft. When the handle is turned, the pressure of the spring causes the ratchet wheel to revolve. On ceasing to turn the handle, the pawl prevents the ratchet wheel from going back, whilst the pressure of the spring is enough to keep the shaft from turning. A slight turn of the handle backwards lessens the pressure of the spring sufficiently to allow the weight to descend, but directly the handle is released, the spring tightens and the downward movement is arrested. In another form of jack, there are two tooth-wheels on the same shaft as the pinion which drives the rack. These tooth-wheels are turned by two four-toothed pinions on a counter-shaft, one set at 45 deg. to the other. By this means friction is lessened, the lifting is more regular, and jerks are avoided. The differential blocks shown by Messrs. Huck are powerful for their size. The gearing is of wrought iron, machine finished and case-hardened, and is all boxed in, the chain-wheel only being outside; the casing, however, is made to open for oiling or cleaning.

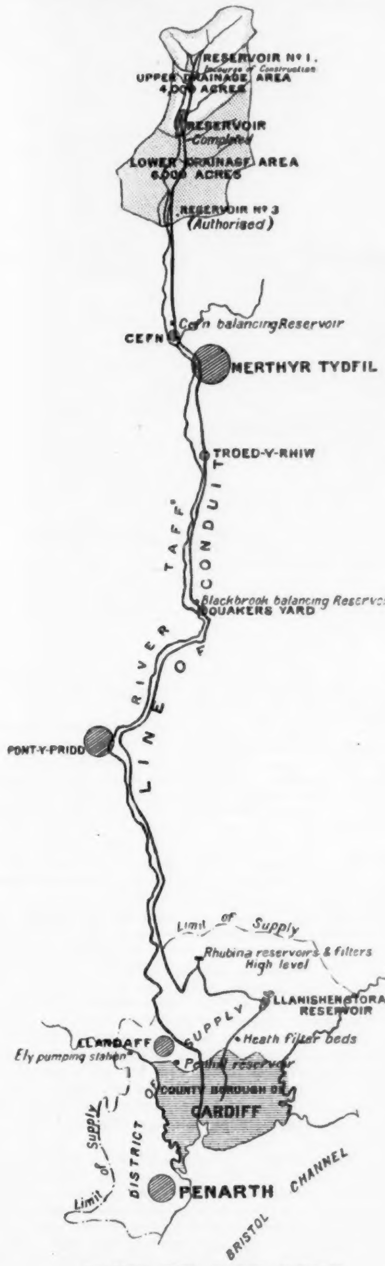
Another useful appliance in this section is a measuring machine exhibited by Mr. J. H. Ermbter, of Neuss. It is intended for measuring and marking all sorts of woven materials, felt, wall-paper, &c. The machine exhibited is constructed for metrical measurements, and will measure up to 1000 metres, showing also $\frac{1}{4}$, $\frac{1}{2}$, and $\frac{3}{4}$ metres, or 10, 20, 30, &c., centimetres. It resembles a small winch; the material to be measured is placed on a roll at one side, with one end passing over the main drum of the machine. A printing disc presses on this, and at each revolution stamps the number of metres. The colour, which dries immediately, can easily be removed, and will not injure silks and other thin textures of light shades. When marked, the material is rolled up at the other side of the machine. The marking disc can be put in and out of gear by a lever, or can in a few seconds be set back to recommence at No. 1. The motive power can be hand, foot, or steam. By employing this machine, the output of a cloth or linen factory can be measured by unskilled persons, and without fear of error; and it is especially useful as a check, for instance, in stock-taking.

A clever arrangement of sliding windows is shown by Mr. F. J. Schürmann, of Münster. On the Continent they usually object to sash windows, because they can only be opened half way, and also on account of the extra expense and trouble required for fitting sash lines, pulleys, and balance weights. But door windows have also their inconveniences. When they open inwards, a space must be kept clear for them; and they rarely shut tightly top and bottom. Besides this, they must either be wide open or entirely closed. An ordinary sliding window running in a groove would also have one of these defects; it would never shut tightly. The window exhibited is suspended; each leaf hangs from two pulleys, which run on a rail above. Either iron or wood can be used for the rail, and where there are shutters, as in the one shown, a bar of channel iron serves as a rail for both. Grooves are cut in the rail, and it is bent towards the casement, at the positions which the pulleys will assume, just before the window is closed. This causes the pulleys, and consequently the window, to make a three-fold motion; it drops the depth of the groove, moves laterally, and towards the frame. The edges of window and frame being cut on the level, this triple movement presses the window firmly against the frame, keeping out all rain or draught. When a strip of wood is used for the rail, the pulleys have india-rubber tires, to ensure their running noiselessly. To open the window, it is first lifted by a lever at the side, which moves the pulleys forward out of the groove; and there is then no trouble in sliding it. The exhibitor says that this window can be supplied cheaper than door or sash windows of the same size; and as it is easier to open, heavier glass can be used, thus keeping out the cold better. The same system can, of course, be adapted to warehouse doors, railway carriage windows, and tram car doors. It was originally devised for a wooden summer-house, but where used for a masonry building, a casing is required into which the panels can slide. This makes them more suitable for wooden buildings, such as are used in the United States, than for an average English or German brick-built house; though possibly some people may consider that they offer advantages which more than compensate for the disadvantage of having to provide a receptacle for the window, when open; and there are many buildings, such as stables and stores, where there is no occasion for the glazed panel to be concealed when the window is open.

Switzerland has only one exhibit of interest to engineers. It is an apparatus for the manufacture of condensed milk, shown by Messrs. Sulzer Brothers, of Winterthur, whose exhibits of brewery plant at other exhibitions have several times been described in THE ENGINEER. The milk is first warmed in an open copper pan, and the requisite quantity of sugar is then added to it. The second operation takes place in a closed copper, into which the milk is drawn from the open pan at a temperature of about 120 deg. Fah. by means of a vacuum pump, which exhausts the air in the copper. This vessel is egg-shaped, and the sides are lagged with wood. It is heated by steam passing through two independent copper worms, and also underneath a false bottom. The level of the milk is seen on a gauge glass, and steam is only admitted to those parts which are covered with milk, so as to avoid over-heating and burning. There are also small cocks through which samples may be drawn, as well as thermometers at different levels, pressure gauges, &c. When the milk is sufficiently evaporated, which requires four or five hours, it is drawn out by the vacuum pump and passes to the coolers. These are forty circular vessels 11$\frac{1}{2}$in. diameter, 26in. deep, in a wrought iron tank. Spur wheels at the bottom of the tank cause the milk pans to revolve, whilst fixed rousers —which are let down into them—stir up the contents and keep the milk from becoming lumpy. Water flows through the tank, and when the cooling—which takes about an hour and a-half—is complete, the milk is ready to pack.

## THE CARDIFF NEW WATERWORKS.

THE Cardiff Corporation, after some unfortunate experiences of the private contract system, resolved to take into their own hands the construction of the extensive chain of reservoirs which are now being rapidly proceeded with in the Breconshire mountains some forty miles northward of the town. A brief account of the opening of No. 2 reservoir was published in THE ENGINEER two years ago; but the work then accomplished represented the least difficult part of the undertaking. A recent visit to the scene of operations shows that great progress has been made in the interval with reservoir No. 1, and reveals at the same time a remarkable transformation in the face of the romantic Taff Vawr valley. Whatever differences of opinion there may have been as to the relative merits of the site, only one view now prevails among engineers and all other visitors to the works, and they have come from the United States and many parts of the Continent. The gathering ground dips down from the crest of the Brecon Beacons to a natural basin at the head of the old river channel. The mean rainfall of the watershed is about 60in. per annum, as compared with 61in. at Vyrnwy, the Liverpool works; 62in. in the valley the Birmingham Corporation are at work in; at Thirlmere, 81$\frac{1}{2}$in. in a dry season, 104in. in a wet year; and 53$\frac{1}{2}$in. at Woodhead, until now the main source of the Manchester supply. The capacity of the three reservoirs is:—No. 1, 335 million gallons; No. 2, 322 million gallons, and No. 3, 670 million gallons. No. 1 is expected to be completed in three years, and it is calculated that with No. 2 it will supply the needs of Cardiff, rapidly as the town is increasing, for ten years. But meanwhile the excavation and embanking of the third reservoir will be commenced with more or less rapidity in proportion as the population of the borough approaches the standard of 280,000, the estimated number in fifteen years time. The vast scheme, it should be added, has almost paid its own way, and as the town, and consequently the number of consumers, becomes greater, it will do so to an even greater extent. According to the chairman of the Water Committee—Mr. Alderman David Jones—it was anticipated that the cost of the undertaking would be met by a rate of 2$\frac{1}{2}$d. or 2$\frac{3}{4}$d. in the pound, and although, through unforeseen circumstances, No. 2 reservoir involved a much larger expenditure than was estimated, the rate has not exceeded 3d., which may diminish as time goes on and an advancing community makes greater demands upon the water supply. The most noteworthy features —see map, next page—of the work executed since last autumn, entirely by Corporation employés, under the personal direction of Mr. J. A. B. Williams, C.E., the water engineer, and the author of the whole design, are the main trench and the discharge tunnel. The main trench, undoubtedly the most important achievement so far, runs across the valley 1060ft. in the open, and 1300ft., including the drivings, into the hillsides. The excavation in some places dips to 75ft., and is now finished, with a concrete bed resting on the solid water-tight rock. At its base the embankment is 400ft. wide, narrowing to 30ft. at the top, and the stone toes may also be said to be practically completed. So with the discharge tunnel, an admirable piece of work, which at present is used to carry off flood water, and will ultimately serve its purpose of draining the reservoir, when it is necessary to cleanse the bed. No inconsiderable amount of engineering skill and costly work, not obvious perhaps to those unfamiliar with the scene of old, were involved in the diversion of two highway roads, one to Brecon and the other to Hirwain, in order to raise their level and widen the limits of the lake. The Corporation possess excellent limestone quarries close to the reservoirs, and the stone and gravel for the concrete is obtained from the old bed of the river and crushed on the spot. There is a complete establishment of engine repairing sheds, wagon-making shops, a fitting shop and smithy, and here all that is needed is done for the locomotives, the one hundred odd trucks, the eight portable engines, and sixteen cranes. Besides these are 7½ miles of Corporation railway to the village of Cefn, where many of the workmen live. For the accommodation of the remainder of the men a little township of well-built houses has arisen by the side of No. 1 reservoir, with a large general store, a post-office, a public reading-room, a schoolroom, a chapel, together with a missioner, who acts as schoolmaster on weekdays and a spiritual comforter on Sundays.



CAFDIFF NEW WATER SUPPLY

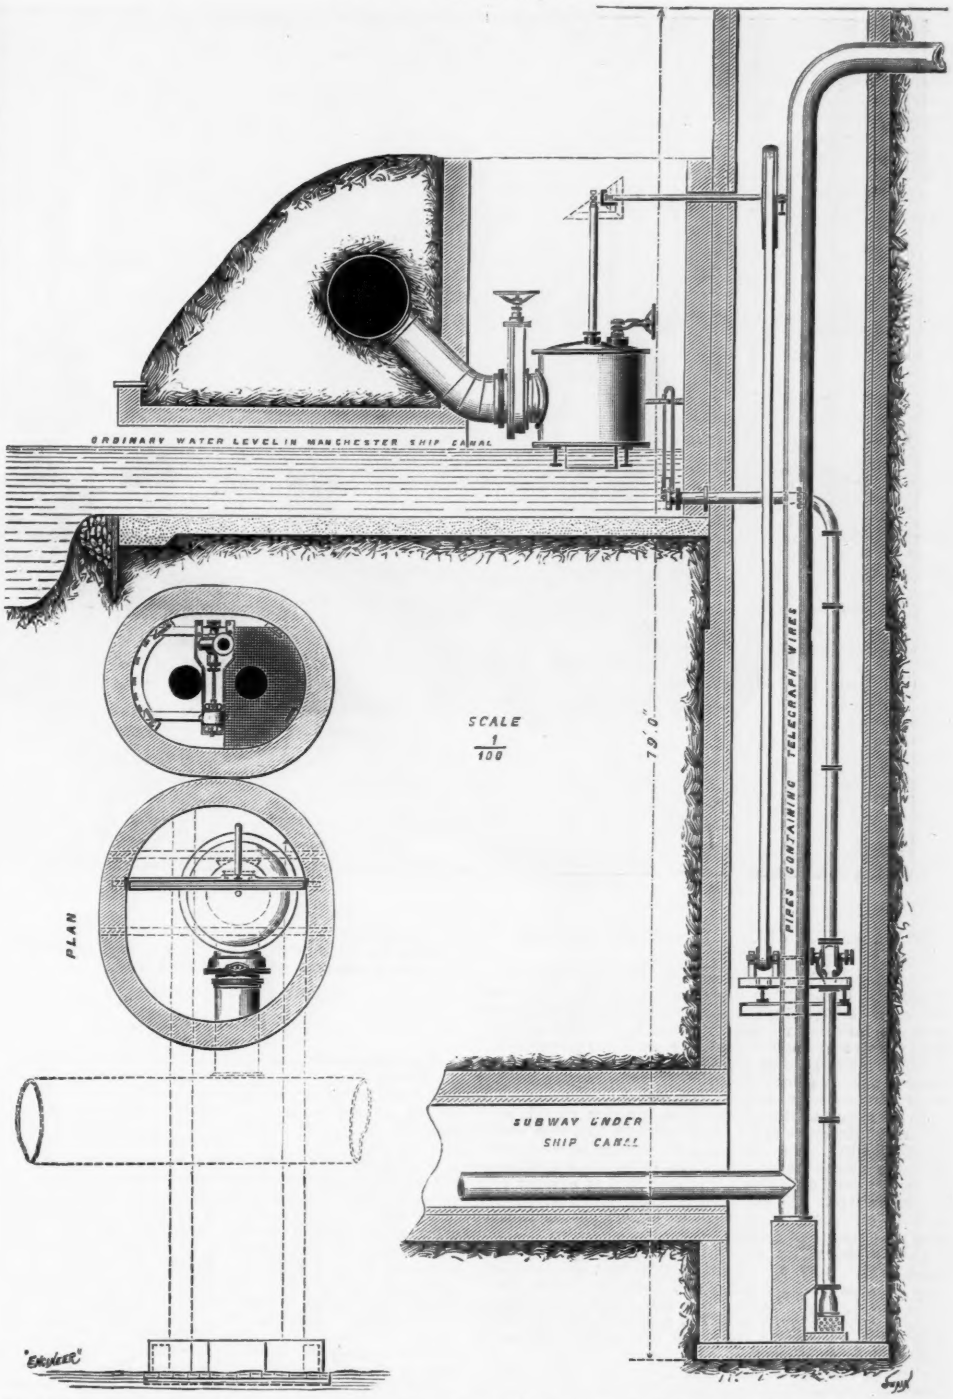
---

## HARBOURS AND WATERWAYS.

*Grand Canal.*—At the half-yearly meeting of this company, held at Dublin, the chairman reported that the net profits for the year amounted to £13,126, which allowed of the payment of a dividend of 3½ per cent. The receipts from the carrying trade showed an increase of £765 over the previous year. During the year the Barrow Canal had been purchased at a cost of £30,000 for the navigation and £2500 for the plant and steamers. It is intended to build ten additional steamers for the Shannon, to accommodate new traffic, and to fit up more barges with steam power. A suggestion was brought forward at the meeting for an extension of the system in order to complete the 750 miles of the canal, which would connect the system with Belfast, Newry, Dublin, Waterford, and Limerick. It was thought that this scheme was beyond the means of the company.

### TURBINE AND PUMP, MANCHESTER SHIP CANAL

MR. C. L HETT, BRIGG, ENGINEER



ORDINARY WATER LEVEL IN MANCHESTER SHIP CANAL
SCALE 1/100
79' 0"
PIPES CONTAINING TELEGRAPH WIRES
PLAN
SUBWAY UNDER SHIP CANAL
"ENGINEER"

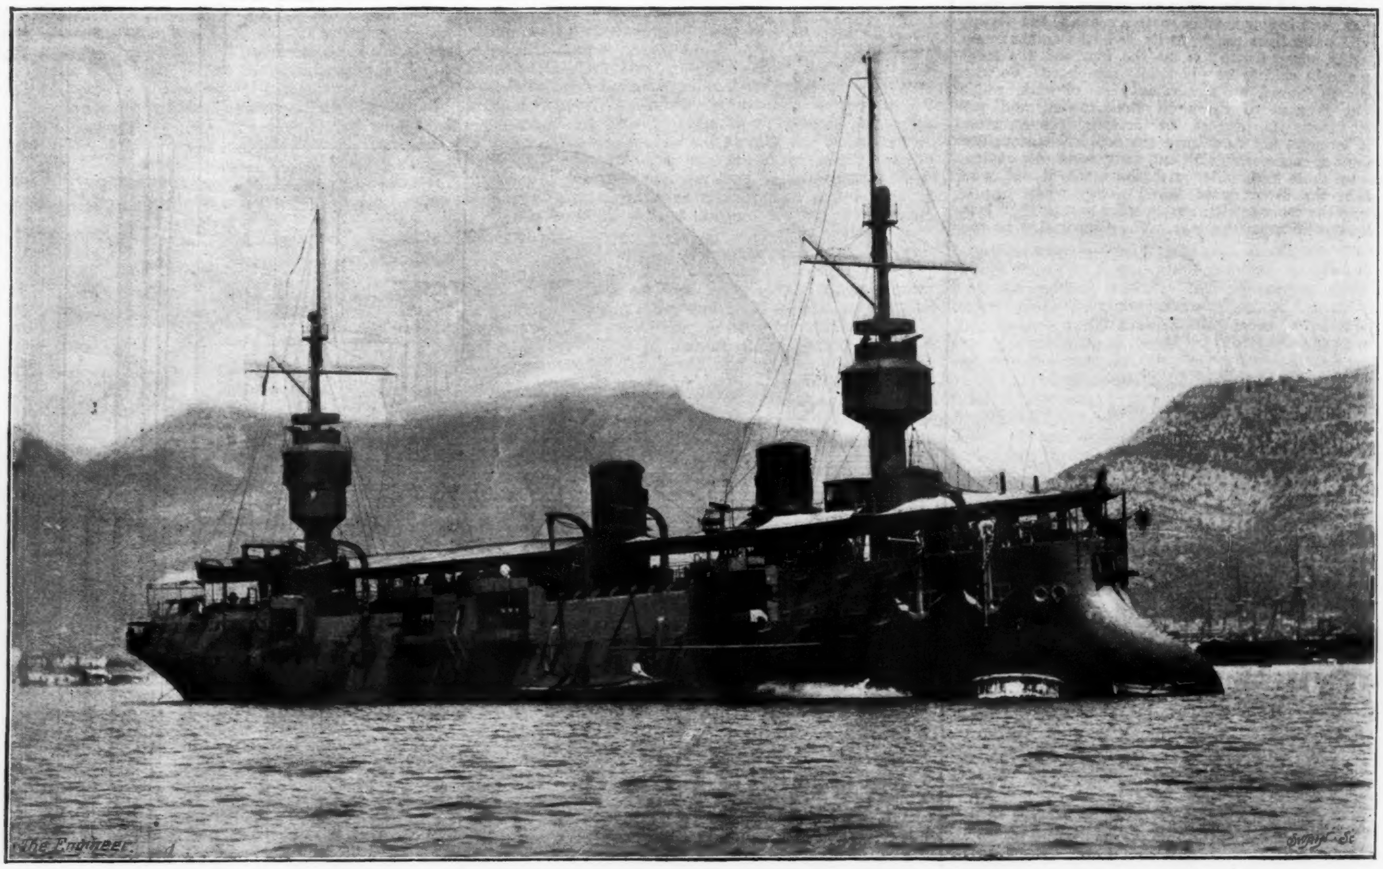
*The Danube.*—Shortly before the close of the last session a report was presented to both Houses of Parliament on the further improvements made in the navigation of the Danube between 1878—1893. The report states that since the final completion of the piers at the Sulina mouth, the depth of 20½ft. has been constantly maintained. At the close of last year it was determined to increase the depth to 23½ft. by constructing parallel dams between the piers to increase the scour and by dredging; a new powerful hopper dredger being now under construction for the purpose. When this increased depth is obtained vessels which at the present time have to complete their cargoes in the roads will be able to carry out their operations in the port of Sulina, and so avoid the delay which occurs when rough weather prevails and prevents the barges lying alongside the vessels. The cutting of a new channel between the eighth and eighteenth miles commenced in 1890, which has suppressed three difficult bends and shortened the course by 4¼ miles, was completed last December at a cost under the original estimate of £152,000. It has now been decided to undertake another cutting 3½ miles long between the thirty-first and thirty-seventh miles above Sulina, for the purpose of doing away with four bends and shortening the course of the river 1⅓ miles, at an estimated cost of £96,000. When the works were first commenced it was intended to secure a depth at low-water of 13ft., and this was attained by training and regulating the channel by groynes. In 1880 a new series of works was commenced with a view of securing 15ft. and removing some of the worst bends. These works were completed in 1889, and the depth of 15ft. was secured, the channel being shortened about two miles. These works were carried out at a cost of £384,000, which was £96,000 below the original estimate, and the advantages secured were very much greater than promised. The works now in hand, it is expected, will give a depth of 20½ft. along the whole of the Sulina branch when the river is at its medium height, and at a season when the shipping is busiest. All the loans effected by the Commission for carrying out the improvements have been paid off, the current income being sufficient to meet the expenses of the works now in hand in addition to the ordinary maintenance. The works have from the commencement been carried out under the direction of Sir Charles Hartley, Mr. Kuhl acting as resident engineer.

---

## MANCHESTER SHIP CANAL.—TURBINE AND PUMP AT TWENTY STEPS BRIDGE.

As promised in our issue of the 3rd of August, we now give an illustration and description of the pumping installation recently put down for the Manchester Ship Canal Company by Mr. Chas. Louis Hett, of the Turbine Foundry, Brigg. The plant is intended to keep the subways—which were made for the purpose of conveying the telegraph and telephone wires under the canal—clear of water, to enable the authorities to inspect the lines at any time. The motive water is obtained from a 48in. main, which connects two streams in the vicinity, from the level of which to the ordinary level of the Ship Canal there is a fall of about 9ft. The turbine is one of Mr. Hett's Hercules type, 60 c.m. diameter, with vertical shaft enclosed in steel case, and fitted with sluice valve for shutting off the water for examination or repairs. The regulating gear of the turbine is mounted on the top of the case. The pump is driven by a belt from the turbine, and is a 6in. Accessible type, designed to lift 600 gallons per minute, with 45ft. lift, at a speed of 1220 revolutions per minute. The presence of the large pipes in the pump well necessitated making a special pump suitable for placing between the pipes, as shown in the illustration. The tail water flows into the Ship Canal through a culvert 3ft. wide, and the pump also discharges into this culvert, the discharge pipe being fitted with a penstock and air pipe to enable the pump to be examined when desirable. On these occasions the water is drawn from the delivery pipe through a cock fitted in the body of the pump. The whole of the work has been carried out under the supervision of the company's engineers, and has been found to fulfil its purpose admirably.

# THE FRENCH CRUISER ALGER



## THE FRENCH CRUISERS ALGER AND ISLY.

The French Minister of Marine has this week ordered the despatch to China of the first-class cruisers Alger and Isly, the latter having actually started on Tuesday, in compliance with the instructions, and the Alger is to follow at once. Both vessels are complete in every respect, but present a very different appearance to that anticipated in their original designs, which was somewhat similar to the Tage—a heavily-masted cruiser, with large sail surface.

An engraving of the Alger, which we give on this page, is equally illustrative of her sister vessel the Isly, both having practically the same class and disposition of armament, almost exactly the same dimensions, and a like arrangement of sponsons and deck plan. The Jean Bart is another ship of similar type. The engraving is taken from a photograph obtained of the Alger, whilst she lay off, completing afloat—as is the custom—at Toulon.

The dimensions, &c., of the Alger are as follows:—Length, 346ft.; beam, 45ft. 3in.; draught, 19ft. 6in.; displacement, 4122 tons; indicated horse-power, 8254; maximum speed, 19·61 knots; coal capacity, 860 tons. The Alger has no vertical armoured protection, but a curved steel armoured deck runs from stem to stern, and this is 3½in. thick—far stouter than as allowed in our cruisers of equivalent displacement, the Astræa type. The armament of the Alger is, moreover, immeasurably more powerful than that of the Fox or Astræa. She carries four 16 cm.—6¼in.—and six 14 cm. —5½in.—quick-firing guns as a main armament, against two 6in. and eight 4·7in. of similar type in the British vessels, and ten smaller quick-firers, with ten machine guns and four torpedo tubes. But what adds very considerably to the effective gun power of the Alger and Isly is the fact that all their eight heavy broadside guns are in protected sponsons, so that an overwhelming end-on power can be obtained when necessary. It has been recently advanced that an effective broadside fire is of greater value than end-on fire, and this must certainly be admitted as regards vessels which are designed for fighting in line of battle, as the effect produced by broadside firing from ships advancing in "line ahead," or "in column," as it would be expressed by landsmen, is absolutely crushing. We assume that the enemy is practically motionless, and "in line abreast." But a cruiser is a free lance, and expected to act, as a general rule, independently, so that her axially directed armament—after her speed—is her great feature.

The Alger and Isly have a high freeboard, in this respect resembling the four large cruisers which are doing such excellent work for the Japanese at this moment, and her coal bunker divisions are so arranged as to add immensely to the security afforded by the armoured deck. The conning towers are thickly armoured, and shelter decks are over all the upper deck gun positions. The fighting masts are of large size, with double staircases, and search lights in the upper tops, as may be seen in the engraving. The Isly attained a speed of 16·8 knots with natural, and 18·1 knots with forced draught, whilst her trials were being made in an exceptionally heavy sea; hence she must be a good seaboat. The Jean Bart has already displayed excellent properties in this respect.

It is clear, then, that France is despatching a very powerful reinforcement to her already strong China squadron, and that if her interests in the East demand such prompt and effective action, Great Britain ought not to be behindhand. The European community in Hong Kong, Shanghai, Hankow, and Tientsin, &c., consists practically of Englishmen, with a few Americans only, except at Tientsin, where they are numerous. The German and French merchants might be counted upon one's fingers. It is, therefore, for us to see whether our naval strength in China is commensurate with our present interests. We do not think it is.

## THE DAIRY SHOW.

The nineteenth annual Show, held under the auspices of the British Dairy Farmers' Association, opened on Tuesday and closed to-day, and amongst the varied and miscellaneous exhibits we noticed as usual various mechanical appliances intended to improve, facilitate, and accelerate the production, treatment, transport, and utilisation of dairy produce. It is not necessary to chronicle the continued appearance of the time-honoured mechanical contrivances of the dairy, but rather to note the direction the mechanical mind has taken in the way of producing novelties for the betterment of the dairy industry during the past year. No great activity has been exhibited during this period in these matters, and what has been done is principally in the improvement of the separation of cream, &c., from milk, centrifugally. The Dairy Supply Co., London, in this direction have made the discs of their "Alpha" separator of a steeper angle, and claim thereby to increase the separating capacity without any increase in the power required for working; whilst to a small pattern of separator, the "Humming Bird," they have applied a strap and ratchet gear, the strap being alternately pulled and allowed to recoil as in some well-known toys, and a thorough separation of cream is rapidly effected with apparently a ridiculously small amount of exertion, the operator casually chatting and answering questions, while the stream of separated milk and cream run regularly from their respective spouts. The Dairy Outfit Co., London, now place within their separator a 1⅛in. thick metal cylinder or drum, for large sizes, made of aluminium. This cylinder is perforated with holes inclining upwards at an angle of 55 deg. in their passage from the outer to the inner surface of cylinder; the stream of milk directed in the usual way, passes up between the periphery of the revolving vessel and the cylinder, the cream passing through the perforations to the inner side of the cylinder, where four wings or blades, provided for the purpose, cause it to pass upwards to be discharged from the cream spout. The use of this honeycombed cylinder is stated to increase the efficiency to such an extent as to permit of seventy-five gallons per hour being separated by means of a small hand machine. This novelty is known as the "Empress" cream separator, and gained a silver medal. These and various modifications in centrifugal testing machines for stimating equality of milk, cream, and butter, are to be seen in number. In the latter graduated tubes containing the milk, cream, or melted butter are attached by their necks to a centrifugal machine, and are whirled round. When the separation is achieved the thickness of the various layers is measured, and the proportion of each constituent is determined. To avoid fracture of these tubes in some cases it is found advantageous to have them immersed in water when whirling. A churn, exhibited by S. Cheeld, of Chesham, consists of an open round vessel—a tub, in fact—which is made to revolve on a table whilst suspended in a socket in a cross piece. Resting on cast iron supports, is an iron rod which can be adjusted to any height and fixed by a screw. This rod at its lower end carries two or more vertical blades extending laterally so as to nearly reach the wall of the revolving vessel. The cream when run in is dashed against these blades, and is rapidly converted into butter or butter-milk. This is called the "E.C. churn." It makes butter with considerable rapidity and with a very small expenditure of power, and for this it gained an award in the butter-making contests. The same maker has also a butter dryer on the same principle, which, by changing the parts, can be readily converted into a testing apparatus.

Messrs. R. A. Lister and Co., of Dursley, Gloucester, exhibit a farmer's separator plant which they call the "Farmer's Rig." It consists of a steam generator, a steam turbine, and an "Alexandra" separator. The steam generator is an elaborated cauldron with fireplace and ash-pit below, and with a wrought iron flue-pipe. The boiler is very small and neatly arranged and the steam turbine makes a very compact arrangement possible. This arrangement is claimed to be more generally applicable than the ordinary arrangements involving the use of an engine, as it of course does away with the accessories inseparable from the establishment and sustaining of an engine, and therefore less space is required, less primary cost, less renewals, and besides no belting; by it, too, 1500 gallons of milk can be separated with the consumption of 28 lb. of coal; and the cauldron can be used for cooking cattle food, the steam for warming the milk as it passes to the separator, and sundry other purposes on a farm. For warming the milk a steam chamber is provided below the feeding cistern. Above this is a false bottom with an opening on the side farthest from the outflow tap; this false bottom rests on metal battens so arranged as to direct the milk over the top of the steam chamber on its way to the tap; hence the milk is only warmed as it flows to the separator, the mass of milk remaining unchanged in temperature, a desirable factor for successful working.

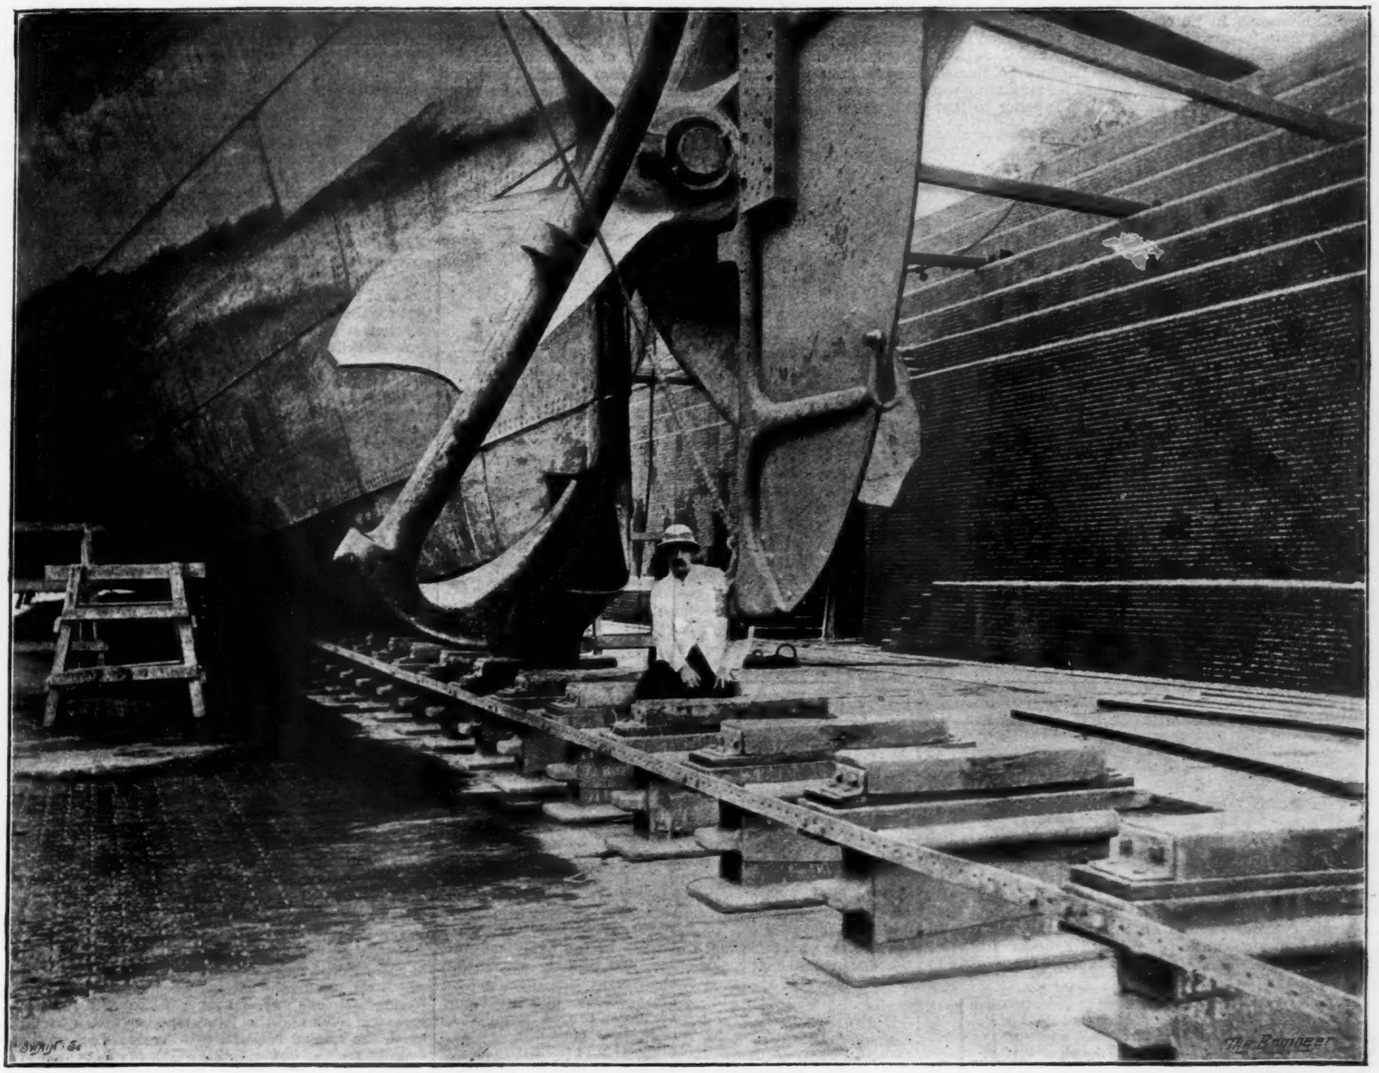
Thomas Bradford and Co., London and Manchester, exhibit a cast iron churn on their fish-back principle. This material was selected to overcome difficulties arising from expansion and contraction of wooden churns in warm climates, and it is stated, and has been verified at the Show, that perfect butter can be made in the cast iron churn, and curiously enough the more rusty the interior of the churn the more satisfactorily does it do its work, provided always that the rust is clean, the product of a good scalding rinse, with boiling water, after churning, with subsequent rusting, until the time for next churning, whether the interval be a day or a week. This exhibit obtained a silver medal.

Messrs. Pond and Son, London, obtained a bronze medal for a refrigerator, which consists of a series of superimposed horizontal tubes, so arranged that the cold water entering at the lowest traverses the whole length of each tube in succession until it leaves the apparatus at the end of the uppermost tube. The milk runs down the outside of these tubes, first encountering the upper ones, finally passing over the lowest and coolest tube before leaving the refrigerator.

There are various vehicles and other appliances that have received awards and attracted some attention, but for reasons already stated do not call for our special notice. The Disc Churn, for instance, is again somewhat prominent; is now mounted differently, and has obtained some successes in the butter-making contests.

We see that steam is making due progress in aiding dairy operations, and we are rather surprised not to see some exhibit illustrating the application of electricity in the dairy, more especially after the recent demonstration witnessed at Mr. James Blyth's dairy at Stansted, Essex. There the cream separator and various butter-making machines are driven by a shunt-wound 1-horse power motor, made by Messrs. F. H. Ruyer and Co., running at 1800 revolutions per minute; it is controlled by a multiple resistance switch. The shafting transmitting the power is coupled direct to the armature of the motor, is 1in. in diameter, and runs near the level of the floor. The power for driving the motor is derived from accumulator, which besides furnish light in various parts of the demesne; the accumulators are charged

# THE BENT STEEL STERN FRAME OF THE S.S. LINLITHGOW



from an Edison-Hopkinson shunt-wound dynamo, driven by one of Marshall's semi-portable compound engines, 12 nominal horse-power. The whole was installed by Messrs. Pritchetts and Gold, of London, and gives great satisfaction. At the time of our visit it certainly was working well, and therefore we are surprised not to see any electrical aids for the dairy at the Show.

## CAST STEEL STERN FRAMES.

The above engraving is from a photograph of the stern of the s.s. Linlithgow, and affords a remarkable illustration of the value of cast steel stern frames. The s.s. Linlithgow, owned by Messrs. Raeburn and Verel, Glasgow, is a vessel of 3137 tons gross tonnage. She was built by Messrs. C. S. Swan and Hunter, Wallsend-on-Tyne, and was fitted with a cast steel stern frame made by John Spencer and Sons. The vessel left Messrs. Swan and Hunter's yard in the early part of this year. On her voyage she went ashore at Gocanada, Bay of Bengal, and twisted her stern frame as shown in the photograph, after which she was towed to Calcutta, put into dry dock, and the stern frame was bent back about 8ft. into position, and the vessel is now returning to London with full cargo.

## PROGRESS OF BESSEMER STEEL.

Considering the general position of the trade of the country, it augurs well for the vitality of the Bessemer steel trade that the production during the first half of the current year should be about 3½ per cent. larger than in corresponding period of 1893. It is true the increase is by no means large, but it is decidedly better than the decline that might reasonably have been expected. The 784,712 tons of the closing half of last year have become 810,392 tons, or an augmentation of 25,680 tons. The details given by the British Iron Trade Association in their official report issued a few days back on this subject are, when examined, both instructive and suggestive. In the first place, it is clear that the material is already being used for much more than rails. In 1882 practically the whole of the ingots produced were made into rails, whilst at the present time considerably more than one-half the ingots are rolled or hammered for other purposes. Another point to be observed about the statistics is the small proportion of available steel-producing plant that is being utilised.

Of the 104 Bessemer converters built in the kingdom, only 60 were at work at the end of June. The relative positions of the various districts with regard to ingot productions are as follows:—1, North-East Coast; 2, South Wales; 3, West Cumberland; 4, Sheffield; 5, Lancashire and Cheshire; 6, Staffordshire and Scotland. The proportion of basic to acid ingots in the Bessemer or pneumatic process, which in the first half of 1893 was 127,938 tons to 656,774 tons, has risen in the corresponding period of the present year to the following:—178,736 tons to 631,656 tons. This being so, we should expect that the acid process should be in vogue where good hematite pigs are near at hand, or easily obtainable, than elsewhere, and this is indeed what the statistics show, for Wales has made 181,839 tons; West Cumberland, 158,930 tons; and Lancashire and Cheshire, 104,532 tons—all of acid. The presence of and proximity to good pig iron in the southernmost portions of Yorkshire is also reflected in the 107,214 tons of acid Bessemer steel ingots made in Sheffield and its locality. On the other hand, in the North of Yorkshire, the presence and almost exclusive use of inexpensive phosphoric ores is shown by the North-East production being 129,142 tons of basic steel ingots, against only 73,141 tons of acid.

The Institution of Civil Engineers.—The rebuilding of the Institution of Civil Engineers will not affect the place of meeting, as such arrangements have been made as will allow of the theatre and reception rooms under to be retained for use during the approaching session.

Port Manchester.—The result of a consideration of circulars issued by the Manchester Canal Company urging the advantages of chartering to and from Manchester has been to cause Baltic men, amongst others, to ask sundry questions, some of which are given in *Fair Play* as follows:—What advantage do merchants gain in sending consignments up the canal?—Was not the freight last year $\frac{1}{32}$d. per pound more than to Liverpool, although steamers paid no canal dues? Is not the carriage by rail from Liverpool to Manchester the same as this difference, *i.e.*, $\frac{1}{32}$d. per pound? (It was stated so some months ago.)—Does not an importer prefer to land at Liverpool and have the advantage of the market there if it cost him no more to send his goods on to Manchester eventually?—Does not the spinner prefer to buy in small lots in Liverpool?—What amount of combination is necessary to get such buying altered to induce people to import cotton they cannot see beforehand, and without the choice of an assortment, it may be?—If spinners buy in large bulks, where will they store them?—Can Manchester offer facilities with as low rates of insurance?—It must be remembered that an expensive equipment is necessary for storage warehouses to enable goods to be received in them and delivered out quickly.—What cargoes which usually come in bulk has Manchester a market for? Timber, grain, and cotton, perhaps.—Does she crush seed like Hull, refine sugar like the Clyde, or weave jute like Dundee?—Does she expect that general cargoes will be sent up to the canal and distributed thence when Liverpool has so many lines of steamers, railways, canals, &c., available, and does not need to send consignments for other ports up to Manchester and bring them down again?—As to outward business, has Manchester any bulk cargoes?—How many of coal has she shipped? Can she offer iron in the bottom of vessels loading general cargo, as many other ports do; or are her principal exports light rather than heavy cargo, which ought to go in last rather than first?—These are a sample of questions which Baltic men and others would like to have answered before they can estimate how many steamers can be chartered for Manchester—profitably, of course. The business might be done magnificently, like the Balaclava charge and the making of the Manchester Canal. But will it pay? That is the question.

## WAVERLEY STATION, EDINBURGH.

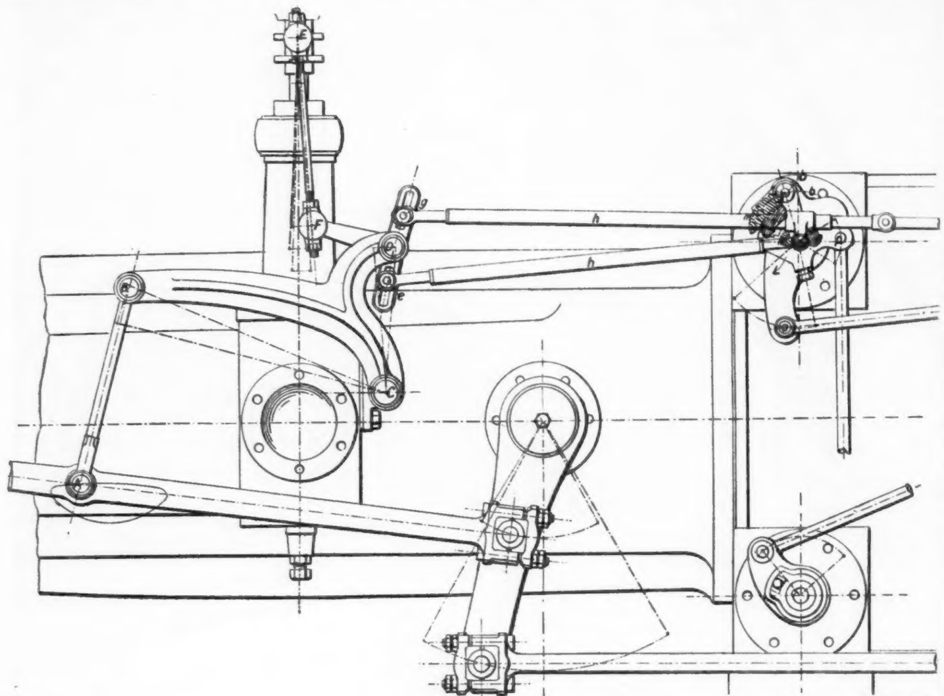
The completion of the tunnels under the Mound, in Edinburgh, which was recently accomplished, is another step towards the much-needed widening of the North British Railway Company's system in traversing the capital of Scotland. The opening of the Tay and Forth Bridges has led to great congestion of the traffic in Edinburgh, and the widening now in active progress is not being carried out a moment too soon. The piercing of the Mound has not been unattended with anxiety, for the material is "made" earth throughout, the Mound being an artificial bank connecting the northern and southern portions of the city, and carrying the valuable buildings of the Scottish Royal Academy, which had necessarily to be guarded from any possible damage from the excavations to be carried out beneath them. The widening has been accomplished by driving a single-line tunnel on each side of the existing double-line. Each new tunnel is lined throughout with cast iron segments having an external diameter of 18ft. 6in. The grouting has been performed with Arden lime, Greathead's patent grouting plant being employed for its injection.

Compressed air has been employed throughout the work, which was commenced in August, 1893. The maximum air pressure attained was 20 lb. per square inch above atmosphere, and the average working pressure may be stated at about 15 lb. per square inch above atmosphere. Thirteen rams of 4in. diameter operated the shield with a pressure ranging about one ton per square inch. Hand pumps were provided for giving pressure. The excavation was carried on in lengths of 4ft. 6in.—the average number of men employed per shift being about twenty. The air-lock, which served both for the passage of men and spoil, was a wrought iron cylinder 12ft. long and 6ft. diameter. The segments were lifted into position by hand, no tackle being employed. Each ring is composed of thirteen segments and a 9in. key piece, the segments being 1ft. 6in. wide, and 7in. deep over the flange. Both back and flanges of the segments are 1¾in. in thickness, and are connected and stiffened by fourteen stout brackets or feathers in each casting. The number of bolt holes in the long and short sides is six and three respectively, and 1⅜in. bolts are employed throughout. The brackets or feathers in the long and short sides are 1⅝in. and 1½in. thick respectively. A special feature to be noted in connection with these tunnels is that the segments are planed on every face, and that no recess is left on the inner edge for filling or packing. On completion the lower portion of the segments of each tunnel are filled with concrete flush to the full depth of the flanges. The faces of the tunnels are elliptical in form to correspond with those of the existing tunnel, and are built of handsome and substantial dressed freestone.

The work has long been looked for with interest by those who travel northward frequently, and especially since the accident which happened near the station about two years ago. It has been carried out by Mr. Geo. Talbot, under instructions from the engineers of the North British Railway Company.

## TRIPLE EXPANSION ENGINE—FRIKART'S SYSTEM.

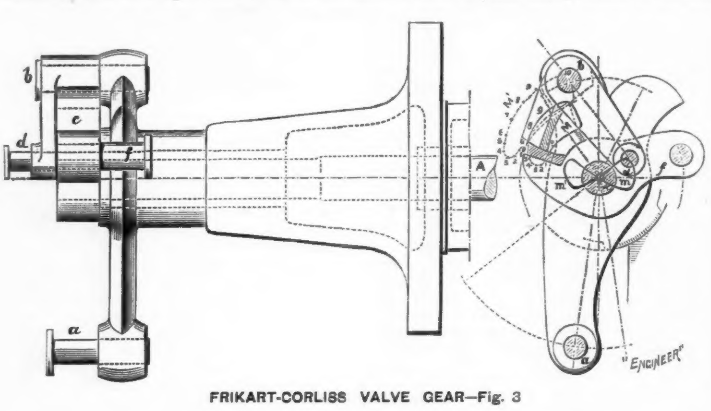
We illustrate on page 322 a triple expansion engine, which is now being shown by Messrs. John Cockerill and Co., at the Antwerp Exhibition. In no country has the rotary valve, which is the main feature of the Corliss system, found more favour than in Belgium. All the large horizontal engines exhibited at Antwerp have valves of the Corliss type, though each manufacturer has a different method for regulating the admission and cut-off which he considers superior to that adopted by rival makers. In Messrs. Cockerill's engines the system used is called the Frikart. They have for some time made single cylinder engines on this principle, and exhibit one of 100 indicated horse-power, with cylinder 1ft. 7¾in. diameter, and 3ft. 5¼in. stroke. This machine is used to drive a dynamo, and works very steadily under a varying load. The application of the Frikart valve to triple expansion engines is quite new, and the one exhibited at Antwerp is the first that has been made. It works at a pressure of 150 lb., and its principal dimensions are:—Diameter of high-pressure cylinder, 1ft. 3¾in.; intermediate, 1ft. 11⅝in.; and low-pressure, 3ft. 1⅜in. The length of stroke is 3ft. 11¼in., and the number of revolutions is eighty.



"The Engineer" Swain Eng

THE FRIKART-CORLISS VALVE GEAR—Fig. 2

The chief characteristic of the Frikart valve is that by it any degree of cut-off from 0 to 75 per cent., or even more if necessary, can be obtained with a single excentric, as the governor completely controls the admission. It is of the highest importance to be able to prolong the admission, as by this means the power of the machine to deal with extreme cases is greatly augmented. For instance, it may be required to exert increased power; or the pressure in the boiler may fall, either accidentally or because the fires are being allowed to burn down before stopping the works. If, as in many machines when the admission of steam extends over more than four-tenths of the stroke, the cut-off only takes place towards the end, this sudden increase in the admission will necessarily make a considerable, and possibly prejudicial, change in the speed. An arrangement by which the admission can be regulated so as to take place through any proportion of the entire length of the stroke, is especially advantageous for compound and triple expansion engines, where there may be a large amount of steam admitted into each cylinder.



FRIKART-CORLISS VALVE GEAR—Fig. 3

In the illustrations, Figs. 2, 3, and 4 show different parts of the back admission valve gear. The piston being at the back dead-point, the cast iron cut-off lever $a\ b$ is in the position shown. This lever works freely on the axle of the admission valve, and carries the part of the trip gear which the makers call the "active." This is in steel, and consists of a finger $b\ c$ and a lever $b\ d$. The "passive" part consists of a lever L, keyed to the end of the valve axle, and connected by a jointed rod to the piston of a dash-pot. The finger $b\ c$ has a tempered steel trigger $c$, bearing on the trigger-plate $k$—also in tempered steel—of the lever L; the piston being always supposed at the back dead-point.

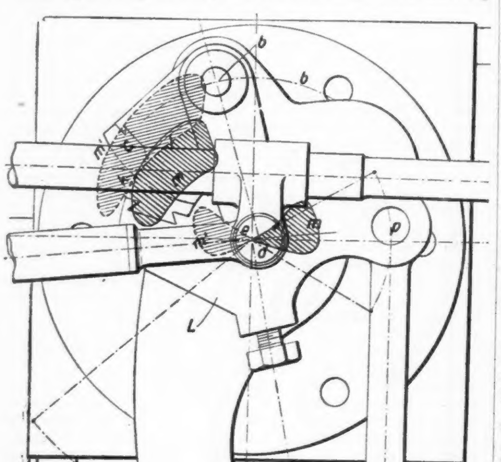


Fig. 4—ENLARGED VIEW OF PART OF Fig. 2

In this position the edges of the back admission valve, and of the orifice, are just touching. The radius to which the trigger-plate $k$ is curved, being equal to the length of the finger $b\ c$, the lead is constant. On leaving the described position, the admission valve will commence to open, and the orifice will be more and more uncovered. But the finger $c$ moves with the small lever $b\ d$; and during the oscillation of the point $b$, the point $d$, which is connected by levers with the excentric rod, will move also, and will follow the curve $m$; consequently the edge of the trigger $c$ will describe the curve M. If therefore from the centre O we strike an arc, passing through the edge of the trigger-plate $k$, the point where this arc cuts the curve M will be that at which the release takes place. At this moment the air piston, connected with the valve gear at the point $p$, brings the whole apparatus back immediately into its original position.

The points 0 to 19 on the curves $m$ and M, and on the arcs $a$ and $b$, correspond to a complete revolution of the crank-shaft; so that it will be seen that in its present position the release takes place at about 0 70 of the back stroke of the piston.

The manner in which the action of the excentric rod causes the point $d$ to describe the curve $m$ is as follows:—The point A of the excentric rod describes a sort of ellipse; its vertical movement is transmitted to the regulating lever B C D, oscillating at C; at the point D is connected a lever with three arms $e\ f\ g$, of which the arm $f$ is joined by a small connecting-rod to the sleeve of the governor. Let us suppose for a moment that this sleeve is fixed, and in its lowest position; the point $f$ will then describe a small arc round it, and the two extremities $e$ and $g$ will move in the same manner as the point D. It is this horizontal movement which, transmitted to the points $d$ by the rods $h\ h$, and combined with the circular movement round the pivot $b$, causes the curve $m$ to be described.

If the sleeve of the governor be raised to its highest position, the point $f$ will be raised also, and the points $e$ and $g$ will undergo a corresponding angular movement round D, whilst continuing to follow the horizontal movements of the same point, the consequence being that the point $d$ will now describe the dotted curve $m^1$, and the edge of the finger $c$ will describe the dotted curve $M^1$. The point 10 of this latter curve is exactly at the extremity of the trigger plate. The trip would therefore take place at the dead point.

For an intermediate position of the sleeve, the point $d$ will describe an intermediate curve between $m$ and $m^1$, and the finger $c$ will describe a curve between M and $M^1$; and thus, by the action of the governor, the admission will vary from 0 to 0·70. The admission of steam to the low-pressure cylinder is fixed and regulated by hand; the cut-off of the low-pressure is therefore constant.

Fig. 1 is from a photograph showing the high-pressure and intermediate cylinders, which are arranged as in a tandem engine. The low-pressure cylinder drives a crank on the opposite side of the fly-wheel from the other two. The condenser and air pump are behind the low-pressure cylinder, and in a line with it. All three cylinders are steam-jacketed; the steam for the jacket of the high-pressure cylinder is direct from the boiler, that for the intermediate from the reservoir or steam chest between it and the high-pressure, and that for the low-pressure cylinder from the other reservoir between the intermediate and low-pressure cylinders. These two steam reservoirs are under the floor, and the water which condenses in the jackets is drawn off by three separate pumps, and returned to the boiler. The engine has been designed for an effective horse-power of 600.

## THE "SIMPLEX" EMERGENCY GRIP, FOR CRANES AND WINCHES.

The engravings below illustrate a new form of self-sustaining device for application to cranes and winches to prevent the too-common accidents with the handles of these machines, or the unintentional and accidental running-down of the load. Fig. 2 of the engravings shows the grip as applied to a derrick or slate-quarry crane; and Fig. 1 shows the details of the grip. Upon the first motion spindle of the winch is fixed a friction wheel, into which gears an excentric friction roller or cam, carried by the handle shown in Fig. 1. The roller thus forms an excentric circular wedge, which will permit the friction wheel on the first motion shaft to run freely one way, but jams or fixes it in the other. The excentric roller and the lever, together with a friction clutch band, are carried between two cheeks, which are kept in a definite position by two links, which connect them to a cross-bar of the frame of the crane or winch. A—Fig. 1—is a cast iron sheave turned with friction grooves on the periphery. This is fixed to the first-motion or handle shaft, and into this friction sheave works the cam-shaped part of the friction lever H, which is held in position by side plates, see Fig. 2. By lifting the handle, the cam is taken out of gear, and the friction clutch band may be used for lowering the load. The "Simplex" grip is readily applied to existing winches, and is made, under the patent of Messrs. Beckett and Roberts, by Messrs. De Winton and Co., of the Union Ironworks, Carnarvon.

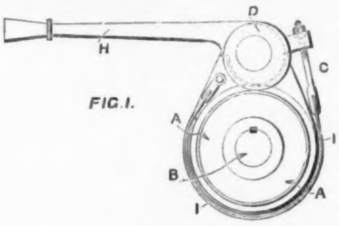

FIG. 1.

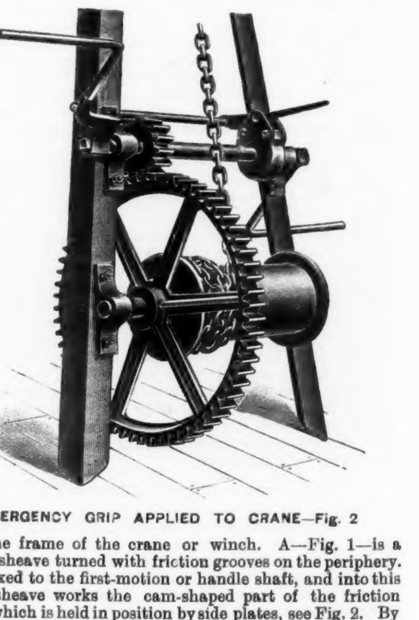


EMERGENCY GRIP APPLIED TO CRANE—Fig. 2

---

The Incorporated Association of Municipal and County Engineers.—The eighteenth voluntary pass examination of candidates for the offices of municipal engineer and surveyor to Local Board carried out by this Association was held at the Council House, Birmingham, on Friday and Saturday, the 5th and 6th of October. Eighteen candidates presented themselves for examination, the written portion of which was taken on the first day. The greater part of the second day was occupied with the *vivâ voce* portion of the examination. The examiners were:—(1) Engineering as applied to Municipal Work, Edward Pritchard, M. Inst. C.E., of Birmingham and London, past president. (2) Building Construction, W. George Laws, M. Inst. C.E., City Engineer, Newcastle-on-Tyne, past president. (3) Sanitary Science, A. M. Fowler. M. Inst. C.E., of Manchester, President. (4) Public Health Law, Joseph Lobley, M. Inst. C.E., Borough Engineer, Hanley, past president. The next examination will be held in London in April, 1895.

## RAILWAY MATTERS.

Railway construction in China is entirely suspended.

It is proposed to construct a new line of railway between Windsor and Henley.

The Philadelphia postal authorities are considering the question of operating postal cars on the electric railway lines in that city.

All of the bridges which were destroyed during the forest fires in Northern Wisconsin and Minnesota have been rebuilt, and traffic has been resumed on all the roads.

It has been decided to use petroleum as locomotive fuel on the Baltic railroad, which is significant, because this line is almost the most distant of any in Russia from the oil wells. Great reservoirs are to be built in St. Petersburg and Reval and three other stations, which will hold in the aggregate about 5,000,000 gallons.

The railway recently opened at Kiew, in Russia, is the first electric railway that has been constructed in that country. It is about two miles long, with grades as high as 9 per cent. The generators, which are two 30-kilowatt machines, are of German make, and are driven by Otto gas engines of 60-horse power. The track is laid with stringer rails.

Three new mogul locomotives for the Erie and Wyoming Valley Railroad, with 56in. drivers, weighing about 56½ tons, have recently been delivered from the Baldwin Locomotive works. They have three 17in. by 24in. cylinders, set on an incline, so as to allow the middle one to drive the main axle just inside the right driver, all being connected at 120 deg., to give continuous effort on account of the heavy grades on the road.

The Melbourne Tramways Company has been experimenting with tar as fuel. The tar is kept in a liquid condition by means of exhaust steam pipes, which are coiled in the tanks, and is pumped to the feed tanks, which are situated above the boilers. It is led from the tanks through a large strainer, before it is delivered to the furnaces through a 2in. pipe. The tar is mixed in the burner with steam, and both tar and steam pipes are provided with flexible joints at the furnace door-plate, so that they can be easily swung back as the furnace door is opened.

The official statistics of the working of French tramways in 1893 give particulars of the operations of light railways and tramways worked either by steam, electricity, or animal power. Of light railways guaranteed by the State there are 645 kiloms. in operation. The light railways not guaranteed by the State comprise 288 kiloms. of line. Of tramways proper there are 100 kiloms. worked by steam, electricity, compressed air, or cable, and constructed at an aggregate cost of 16,469,500f. Tramways worked by horses represent a length of 635 kiloms.

In a recent number of the *Revue Générale des Chemins de Fer*, the results of a number of tests to determine the steam consumption of locomotives per indicated horse-power per hour are given by M. Desdouits. In five trips the speed averaged from 37·2 to 40 3 miles per hour, and the average consumption of water 25 61 lb. per indicated horse-power per hour. M. Desdouits believes his experiments warrant him in concluding that in simple engines the best results are obtained with a working pressure of about 142 lb., with a cut-off at one-fifth the stroke, and with the valve given inside clearance.

Information from an American source reaches us of a novel method of removing rusty bolts from locomotive frames, viz., by gun fire. A special gun was made from an old crank pin 10in. long and 5in. diameter, bored with a 2in. hole about 8in. deep. The gun stood on the lower bar of the frame, being blocked up to bring it near enough to the bolt which was to be fired out. About 4in. from the muzzle, a ¼in. vent hole was bored to relieve the internal pressure when the projectile, which was in the form of a ram 8in. long, turned to an easy working fit in the 2in. bore, has done its work. With less than ½ oz. of gunpowder, a 1¼in. bolt was driven out with no more trouble than was entailed by the preliminary setting of the gun.

An appropriation of £30,000 has been made by the United States Congress for the preliminary work on a ship railway to be constructed through the Dalles, on the Columbia River, in Oregon. The car that will be used will be 40ft. or 50ft. in breadth, and long enough to carry vessels that can steam up the river, which in the spring months, when the water is high, will allow a draught of about 14ft. The car will be sunk under water and the vessel floated over it; the car will then be raised by a hydraulic lift some 70ft. above the water level to the height of the land track and the car run upon it. The *American Engineer* says this land track will consist of four or five railway tracks of standard gauges, and there will be no curves sharper than 2 deg.

Mr. Edmund Pearse Burd held inquiries at Nottingham and Leicester on Tuesday and Wednesday, on behalf of the Local Government Board, as to the demolition of houses by the Manchester, Sheffield, and Lincolnshire Railway Company in the construction of their line to London. At Nottingham Sir S. G. Johnson stated that some eight or ten years ago there arose an exceedingly wild building speculation in that town. Land went up in price, houses were placed upon it, and the town became so overbuilt that there were at one time fully 6000 empty houses. The line of railway, so far as it passed through the central parts of the town, would involve the destruction of a lot of insanitary property which had been condemned long ago. A large number of insanitary houses will also be demolished at Leicester.

The Berlin local authorities have decided to call upon the Grand Berlin Horse Tramway Company to proceed at once with the work of laying a tramway from Reichenbergerstrasse to Treptow, as otherwise the project will be passed over to another company. The *Electrical Engineer* says a tramway is also to be constructed in Berlin from the Wienerstrasse *viâ* Wienerbrücke and Köpenicker Weg to Treptow. The Berlin municipality have also sent a deputation to Dresden to see Mr. Langen's electric tramway there. The Berliner Elektricitäts-Gesellschaft has formulated a scheme for the erection of an electrical station at Harburg for working an electric tramway, as well as for the supply of current for lighting and motors. The Elektricitäts-Gesellschaft "Union," of Berlin, have been negotiating with the Elbing Municipality to build an electric tramway in that town.

The first town in Europe to substitute electricity completely for other methods of propulsion upon the tramways is Havre, where the new system of tramcars has lately been inaugurated. Three lines, of a total length of 14 kiloms., have already been constructed, and a fourth is now being laid down. The system employed is the overhead contact by copper wires carried at a height of 6 m. 50 cm. upon metallic posts placed at about 40 metres apart. There are 560 of these posts of tube steel, which are also utilised for carrying arc lamps, of which eighty-five have so far been erected. It is expected that lamps will be placed shortly over the whole length of the lines. This installation has been carried out by the Compagnie Thomson-Houston. The cars are forty in number, and are each capable of carrying fifty passengers. Some of the cars have two motors, while the majority have only one; these motors are geared directly on to the axle, and every care has been taken to protect them from the dust and damp. The power is supplied by the Société de l'Energie Electrique, whose station is situated in the centre of the town. Their plant includes at present three Thomson-Houston dynamos that are worked by a Farcot engine.

## NOTES AND MEMORANDA.

The mean density of the earth found by Professor Poynting is 5·49. Professor Boys' result is 5·53.

A rule given by Mr. Preece for comparing the costs of gas and electricity for lighting is as follows: "Gas at three shillings per thousand cubic feet equals electricity at sixpence per kilowatt-hour," or in other words the factor is about six.

In the city of Tokio and elsewhere in Japan wooden water-pipes have been in use for over 200 years. Pipes of 6in. internal diameter and less are made from tree trunks bored out; larger ones are usually square, and are formed of planks fitted together.

An attempt made in Sweden to produce an extra strong cast iron, in order to reduce the thickness of shrapnel shells, so that the capacity of the chamber within them can be increased, produced a series of castings giving an average tensile strength of 19 5 long tons per square inch, with ·38 per cent. extension in 4in. The firm which makes the castings guarantees a strength of 17·8 long tons per square inch.

In the return of the gas testings for the week ending 6th October, Mr. W. J. Dibdin, F.I.C., enters as the highest mean illuminating power that of the Tooley-street district supply, South Metropolitan Gas Company, which was 17 0 candles. The lowest being found at the Chelsea, Holloway, and Hampstead districts, Gas Light and Coke Company, and the Old Ford district, Commercial Gas Company, which were all 16·1.

Polished steel surfaces as saws, chisels, bits, &c., can be rendered rust-proof by making a preparation as follows: Take one-half ounce camphor, dissolved in one pound of melted lard, take off the scum, and mix in as much black lead—graphite—as will give it an iron colour. Clean the tools, and smear with this mixture. After twenty-four hours rub clean with a soft linen cloth. The tools will keep clean for months under ordinary circumstances.

A chromo-photographic camera, by which a quick succession of photographs can be taken, suitable for combining in a zoetrope apparatus, so as to give an animated reproduction of a moving figure, has been invented by M. George Demeny. The problem to be solved is the same as that of Edison's kinetograph, but M. Demeny's apparatus is much simpler than Edison's, besides being portable. The instrument can be seen at the Anglo-American Import Office, 368, Rue Saint Honoré, Paris.

In a paper recently read before the Paris Academy of Sciences M. Henri Moissan states that aluminium can be saturated with nitrogen by passing a current of the latter through a bath of the molten aluminium, and that such saturation has considerable effect upon the physical properties of the commercial metal, reducing the elastic limit from 4·76 tons—of 2240 lb.—per square inch to 4·13, and reducing the breaking stress from 6 98 to 6·10 tons per square inch. The elongation also drops from 9 per cent. to 6 per cent. The presence of more carbon than is ordinarily found in the commercial metal also reduced the tensile strength and the elongation.

M. Forster, of the Berlin Observatory, has communicated to the *Revue Scientifique* the result of a series of observations carried on simultaneously for twenty months past at Kasan in Russia, Marburg in Germany, and Bethlehem in Pennsylvania. The object was to study the question of the supposed oscillation of the axis of rotation of the earth. From about 10,000 observations it appears that the pole or end of the axis has an oscillation following a spiral traced from west to east. The rate of oscillation is variable; at the present time it is decreasing. It appears, however, that the actual extent of this movement is very small, not exceeding fifteen metres.

Professor Kennedy recently stated that before the Edison and Swan lamp patent expired, and when current was sold at 8d. per unit, an 8-candle power glow lamp cost almost ¼d. per hour of actual lighting, whereas at the present price of glow lamps, and taking current at 6d. per Board of Trade unit, the 8-candle power lamp costs ⅛d. per actual hour of lighting. Professor Kennedy estimates the average life of glow lamps at 500 to 600 hours of actual lighting. The earning capacity of lamps in private houses, hotels, and shops is, according to Professor Kennedy, inversely as the above order. The number of lamps of 8-candle power installed in London in 1893 was 9,666,000.

In a recent paper in the *Comptes Rendus* on "Geodesy and its Relations with Geology," by M. H. Faye, the author says:—Gravity has a greater numerical value in islands than in the midst of continents, as the constant is determined by pendulum observations; this is probably due to the more rapid cooling of the crust of the earth beneath extensive seas, as evidenced by the low temperature of water—1 deg. or 2 deg.—at depths at which the temperature is about 133 deg. in land. The greater average density owing to the lower temperature accounts for the higher value of the constant at sea, notwithstanding the replacement of so much solid matter by the specifically lighter water. The author then draws attention to the need of aid from geologists in the further elucidation of the reasons for variations in the constant of gravity.

An improvement in the manufacture of plumbago or graphite has been described in a recent patent specification. Graphite crushed and passed through a sieve of from 120 to 150 meshes per inch, is stirred into a saturated solution of alum or aluminium sulphate at 212 deg. Fah.; steatite is then added, and more water if required. After mixing, excess of water is evaporated until a consistency suited to grinding in a chilled steel or other mixer is obtained. More graphite may here be added; then, after thorough grinding, the material may be compressed into cakes for household use, or is ready for the manufacture of pencils or crucibles. The average formula for the mixture is: Graphite, 80; steatite, soapstone, or talc, 14; alum, 6; but this varies with the purpose to which the material is to be applied. When several different kinds of graphite have to be employed, the richest in carbon is first mixed into the alum solution. By this process graphites previously regarded as incapable of being compacted are utilisable, and are improved in polishing power; for pencils, the material may be hard without being brittle, and black without being soft; while crucibles made from the treated graphite are at once harder, more durable, and lighter.

A solution of copper sulphate does not conform rigorously to the form in which Faraday's law of electrolysis is generally expressed. It has been shown by Gray that the metallic deposit is heavier the higher the current density and the lower the temperature, an explanation being given in the fact that copper dissolves to a very appreciable, although variable, amount in solutions of copper sulphate. According to Schuster, it is probably the atmospheric oxygen present in the solution that causes this chemical corrosion. In view of this, W. Gannon has sought to discover whether there is any difference between the weights of the two deposits in two copper voltameters, one of which is placed in a vacuum. Freshly made neutral copper sulphate solution was employed, and the electrolysis in one case was conducted first under reduced pressure, with the result that a heavier deposit was thrown down than was the case in a similar experiment, the pressure being that of the atmosphere; but the percentage difference was not constant. The *Electrical Review* says the addition of a little sulphuric acid to the voltameters caused this difference to be constant within experimental error. Under this condition, for current densities above 0 01 ampère per square centimetre of active cathode, there is no practical difference in weight between the two deposits, but for lower densities the "vacuum deposit" is very appreciably higher than the "air deposit.

## MISCELLANEA.

A survey of the Sea of Marmora has been undertaken by the Russian naval authorities in consequence of the submarine disturbances supposed to have been produced in that sea by the recent earthquakes.

The first German ironclad built in the new Dantzic dockyards will be launched this month. It belongs to the Siegfried class, the armament consisting of three 36-ton guns. The indicated horse-power is 4800, and the displacement tonnage 3495.

Experiments with the Sims-Edison steering torpedo are to be made in the Bosphorus. This weapon gave such good results when recently tried at Toulon, that the Ottoman Government are thinking of adopting it for the protection of their waterway.

A new twin-screw steamer, named the Alma, built for the London and South-Western Company's fast passenger and mail service between Southampton and Havre, has been launched at Glasgow. Her length is 270ft., breadth 34ft., and gross tonnage about 1100.

We have received the second edition of Mr. L. B. Wells' canal map of England and Wales. The names of many junctions of canals owned by different companies have been added, and a few additional miles of waterways shown, bringing up the total to 3935 miles.

The Admiralty have directed that trials are to be made on the new torpedo boats and torpedo destroyers on their delivery from the contractors, to test the flaming of the funnels when steaming. It is expected that with careful stoking this evil, which would render a night attack impossible, can be prevented.

The French Government has decided to proceed with the construction of two great docks at Cherbourg—one for the use of those mail boats which will serve as auxiliary cruisers in time of war, and the other for the accommodation of ironclads of the largest size. The docks are to be built in the northern portion of the arsenal.

The Local Government Board have given their sanction to a loan of £11,500 for the sewerage and sewage disposal of Bracknell. The sewage will be purified by irrigation, on 22½ acres of land. There are to be two small pumping stations, worked by oil engines. The engineer to the scheme is Mr. W. H. Radford, C.E., Nottingham.

A curious accident has happened at Boston, U.S.A. A man, while cleaning an arc lamp at the top of a high mast, received the full strength of the current and was killed instantaneously. His body was suspended from the wires for half an hour. When men were put to work to remove it one of them came in contact with it, and was thrown head foremost on the sidewalk. He was dashed with such violence against the kerbstone that he died shortly afterwards.

The Halcyon torpedo gunboat, constructed at Devonport, and engined by Hawthorn, Leslie, and Co., has broken down seriously. A crack nearly a foot in length has been discovered in her high-pressure cylinder. The Admiralty had intended that she should represent her class in a series of experimental trials to ascertain the most suitable type of propeller for torpedo gunboats of the same tonnage. The vessel's machinery was only a few weeks ago accepted from the contractors.

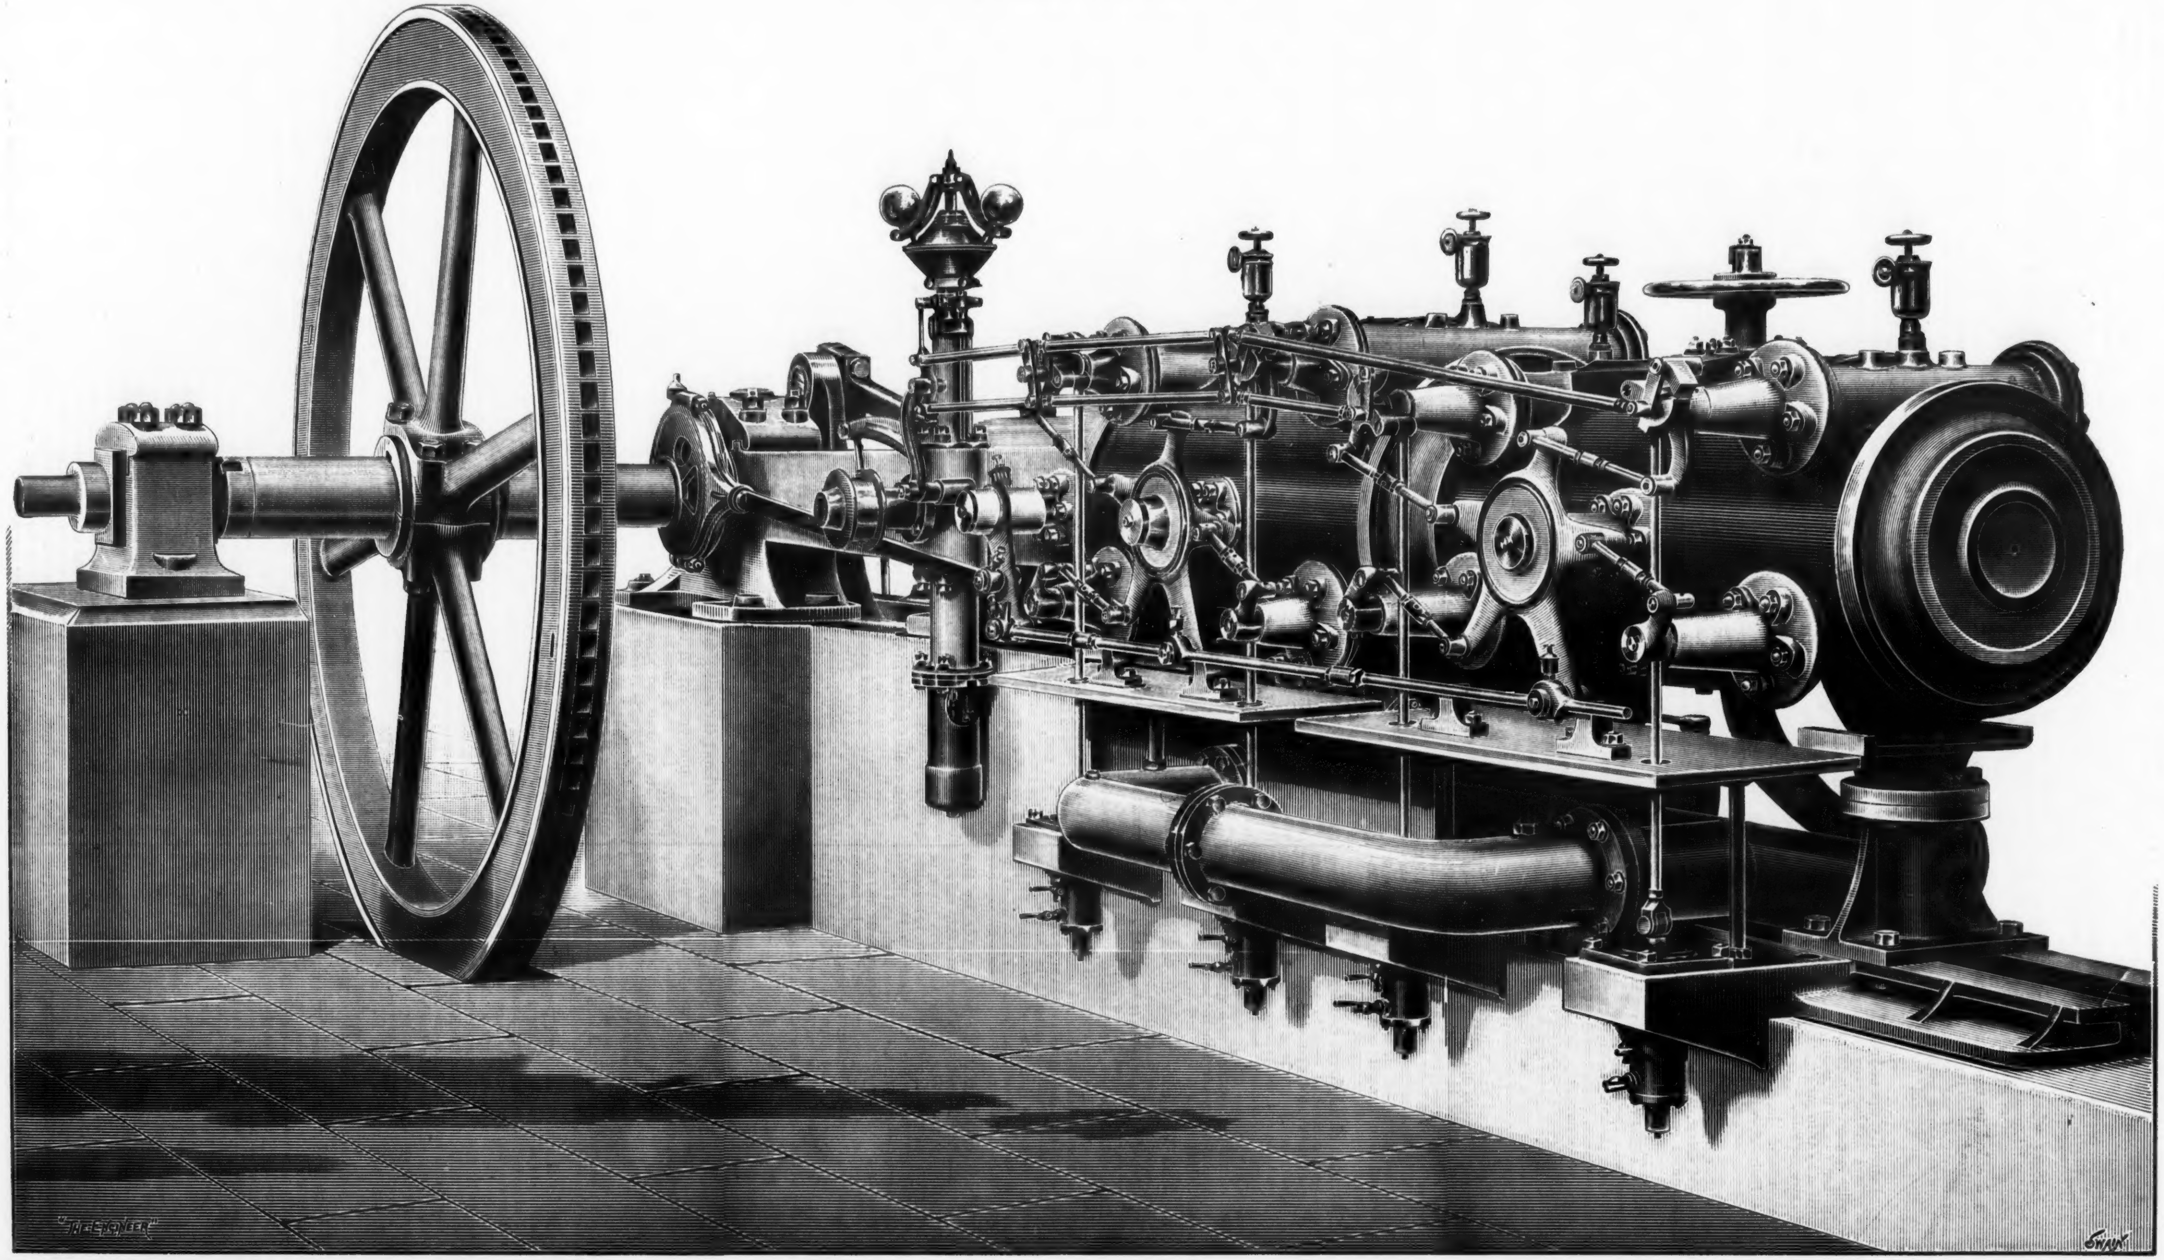
A statement to be taken *cum grano* is to the effect that two Russian engineers contemplate making an attempt to raise the sunken battleship Victoria, owing to their recently achieved success in raising, by means of air balloons, a vessel sunk in 30ft. of water near Varsovie. In the case of the Victoria, it is said, ten air vessels will be used, each of a capacity of 60,000 cubic feet. The question which immediately occurs to us is, how are these vessels to be attached to the ship? 30ft. of water is one thing, and 450ft. is another.

Messrs. John and Henry Gwynne, of Hammersmith, have entered upon a contract with the Mersey Docks and Harbour Board, Liverpool, to supply a set of their "Invincible" compound condensing pumping engines to raise the level of water in the Canada Huskisson dock system. This makes the fourth large installation fitted up by Messrs. J. and H. Gwynne for the same authority, which will have within the dock estate "Invincible" plant equal to a combined capacity of 4000 tons of water per minute when the new machines are at work.

A series of experiments is being conducted on board the first-class battleship Revenge at Spithead, with a view to determine the precise advantage obtained by the new bilge keels which are being fitted to all the vessels of the Royal Sovereign class. At the first trial, the vessel was given a degree of stability and steadiness by her double bottom being filled with water, and her bunkers with coal. The four barbette guns, each weighing 67 tons, were then trained at right angles, which gave the vessel a list of twelve and a-half degrees, and this was increased to fifteen when the crew were assembled on the side to which the guns were trained. It has been decided to subject the ship to a far more severe test, by removing both the coal and the water, and adopting the same method of carrying out the test. At the conclusion of the trials the Revenge will be docked, and bilge keels affixed to her bottom, and she will then undergo the same experiments as before.

We have received from Messrs. Edgar Allen and Co., Sheffield, a pamphlet containing particulars of, and reports upon, their dynamo magnet steel castings. The reports are by Mr. Gisbert Kapp, M. Inst. C.E., Professor Ewing, and Professor Jamieson. It has been for some time known that these steel castings were equal and now are superior to wrought iron forgings for dynamo construction. Mr. Kapp, very early in their history, tested their materials, and his great experience in dynamo design and construction enabled him to make use of this magnet steel, and to pronounce an authoritative opinion upon it. He found it better than wrought iron forgings in many cases, and some which he tested in April this year he speaks of as better than any magnet steel he had previously met with. The pamphlet we have received is accompanied by permeability curves by Mr. Kapp, and Professors Ewing and Jamieson, and will be found of considerable interest by those who are concerned with the construction of large magnets of any kind, and who are interested in the magnetic efficiency of materials to be employed.

The new German third-class cruiser, provisionally known as "F," will be launched and named on the 15th inst. at Wilhelmshaven. She is, according to the *Times*, 246ft. long by 33ft. 6in. broad, and at a mean draught of 15ft. will displace 1640 tons. There are twin screws, and engines working up to 2800-horse power, which will give the vessel an extreme speed of 16 knots. The hull is of steel and wood. The armament will consist of eight 3·96in.—40-pounders—quick-firers, four machine guns, and two torpedo-launching tubes. A few days later at the same yard the keel plates will be laid of the new first-class battleship which is to take the place of the now almost obsolete Preussen, a vessel twenty-one years old. The new ironclad will be a reproduction of the Wörth, with, however, slight modifications, and will be constructed to carry four 11in. breech-loading guns of 40 calibres, two 11in breech-loading guns of 35 calibres, six 3·9in. quick-firing guns of 35 calibres, eight 3·4in. quick-firing guns of 30 calibres, two 2·3in. boat guns, and eight ·31in. machine guns. Her extreme speed, with forced draught and at 111 revolutions, will, it is anticipated, be 17·2 knots, 10,230 indicated horse-power being developed.



"THE ENGINEER"
SWAIN

SIX HUNDRED HORSE-POWER TRIPLE-EXPANSION FRIKART-CORLISS ENGINE

MESSRS. JOHN COCKERILL AND CO., SERAING, ENGINEERS

(*For description see page 320*)

### FOREIGN AGENTS FOR THE SALE OF THE ENGINEER

PARIS.—Boyveau and Chevillet, *Rue de la Banque.*
BERLIN.—Asher and Co., 5, *Unter den Linden.*
VIENNA.—Gerold and Co., *Booksellers.*
LEIPSIC.—A. Twietmeyer, *Bookseller.*
NEW YORK.—International News Company, 83 *and* 85, *Duane-street.*

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

W. B. (Adelaide, S.A.) - *Consult the "Moulder and Founders' Pocket Guide," by F. Overman, published by Sampson, Low, and Company, London.*

A. E. (Stoke Newington).—*Make use of a little elementary geometry and wood splines to get parallel lines, project them upwards by means of plumb bobs hanging from the edge of a board or of a spline temporarily fixed overhead or from the piece of shafting to be set in position; use a spirit level, and with some practical experience and less reliance on cookery book engineering you will manage what you want.*

### ALUMINIUM BRONZE PIPES.

(*To the Editor of The Engineer.*)

Sir,—I shall feel much obliged to any reader who will tell me where I can obtain aluminium bronze pipes which will be safe at 600 lb. pressure, the diameter of the pipes to be 10in. or 12in. Americus.

October 6th.

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)* .. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. £0 18s. 0d.
*Yearly* .. .. .. .. .. .. .. .. .. £1 16s. 0d.
Thick Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. £1 0s. 3d.
*Yearly* .. .. .. .. .. .. .. .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

### MEETINGS NEXT WEEK.

Newcastle-upon-Tyne Association of Students of the Institution of Civil Engineers.—Wednesday, October 17th. Visit to the Consett Iron Company's works at Blackhill, Co. Durham.

Hull and District Institution of Engineers and Naval Architects.—Monday, October 15th, at 8 p.m. Paper: "Hull Steam Shipping," by the President, F. H. Pearson.

North-east Coast Institution of Engineers and Shipbuilders.—Tuesday, October 16th, at 7.30 p.m. Minutes of closing business meeting for last session. Ballot for new members. Adoption of tenth annual report and financial statement. Inaugural address of President.

### DEATH.

On August 31st, suddenly, at Buenos Ayres, S.A., W. H. Morrow, A.M.I.C.E., aged 50.

# THE ENGINEER.

*OCTOBER* 12, 1894.

### THE UNCERTAINTIES OF SCIENCE.

Some months ago we reviewed an important book, "The Science of Mechanics," by Dr. Ernst Mach, professor of physics in the University of Prague. That book gave sufficient evidence that its author is a very advanced thinker—a man with small respect for authority in science. In the *Monist* for October we find a lengthy paper by Dr. Mach on "The Principle of the Conservation of Energy," which will supply food for thought to everyone interested in physics. This paper is remarkable in various ways. Thus, at the outset, we have actually an attempt at a definition of the word Energy. "The most multifarious physical changes, thermal, electrical, chemical, and so forth, may be brought about by mechanical work," says Dr. Mach. When such alterations are reversed they yield anew the mechanical work in exactly the quantity which was required for the production of the part reversed. *This is the principle of the conservation of energy;* "energy" being the term which has gradually come into use for that "indestructible something" of which the measure is mechanical work. Thus then we see that an advanced physicist can find no better definition for a word in everybody's mouth than that it is an "indestructible something." It is *not* work, but work is its measure. It is not, however, with Dr. Mach's definitions that we are concerned, but with his methods. These appear to us to be altogether admirable. He is not content to state ideas, or to give definitions; he goes much further. He asks where did the ideas—or as we prefer to call them, concepts—of physics come from? and the result of his investigations casts a curious light into very obscure regions. As to the doctrine or concept of the conservation of energy, he asks where did it come from? And he proceeds to show that the answer is by no means so simple as it appears, and that indeed it is in no way easy to prove that energy is really always and at all times conserved. It is not our purpose to follow him through his arguments: for the present we are considering only his conclusions. Page by page we find the words, "Not proven." He takes argument after argument, authority after authority, and shows that there is a reason why each and all break down somewhere or in some point. He shows that one of the strongest arguments in its favour is based on the assumed impossibility of producing "perpetual motion," which assumption is in turn based on another, that all forms of energy are modes of motion, concerning which he says, "Intelligible as it is, therefore, that the efforts of thinkers have always been bent upon the 'reduction of all physical processes to the motion of atoms,' it must yet be affirmed that this is a chimerical ideal. This ideal has often played an effective part in popular lectures, but in the workshop of the serious inquirer it has discharged scarcely the least function."

We have said enough, perhaps, on this point to show what manner of thought Dr. Mach puts before his readers on one question. But he is much more audacious in his method of dealing with thermodynamics, and to his views on the subject we direct particular attention. Dr. Mach gives a most simple and lucid exposition of what Carnot did and did not teach, and he explains very clearly the nature and truth of the work done by the Thomsons, Joule, Mayer, and others. It having been shown that heat was not a substance, the question was asked—What, then, is it? The answer, as is well known, is that it is a mode of motion that has been accepted implicitly for years by students as demonstrably true. Dr. Mach hastens to prove that it is not demonstrably true at all, and, *more suo*, he asks: Where did the concept originate? "The generally accepted notion of a caloric, or heat-stuff, was strongly shaken by the works of Mayer and Joule. If the quantity of heat can be increased and diminished, people said, heat cannot be a substance, but must be a motion. The subordinate part of this statement has become much more popular than all the rest of the doctrine of energy. But we may convince ourselves that the motional conception of heat is now as unessential as was formerly its conception as a substance. Both ideas were *favoured or impeded solely by accidental historical circumstances.* It does not follow that heat is not a substance from the fact that a mechanical equivalent exists for quantity of heat. We will make this clear by the following question which bright students have sometimes put to me:—Is there a mechanical equivalent of electricity, as there is a mechanical equivalent of heat? Yes, and no. There is no mechanical equivalent of quantity of electricity as there is an equivalent quantity of heat, because the same quantity of electricity has a very different capacity for work, according to the circumstances in which it is placed; but there is a mechanical equivalent of electrical energy. Let us ask another question. Is there a mechanical equivalent of water? No. There is no mechanical equivalent of water, but there is a mechanical equivalent of weight of water multiplied by its distance of descent."

Dr. Mach here explicitly states a circumstance which must be taken count with in all attempts to identify heat and electricity. That is to say, our existing concepts and definitions based upon those of heat and electricity are fundamentally different. Once more Dr. Mach asks why this difference in conception? and he answers, "The reason is purely historical, wholly conventional, and, what is still more important, is wholly indifferent." This, he proceeds to prove, and concludes his argument with the following pregnant statement: — "When we wonder, therefore, at the discovery that heat is motion, we wonder at something that was never discovered. It is perfectly indifferent, and possesses not the slightest scientific value, whether we think of heat as a substance or not. The fact is heat behaves in some connections like a substance, in others not. Heat is latent in steam as oxygen is latent in water." We have quoted at considerable length, because without quotation we have found it impossible to do full justice to Dr. Mach's views. Even now we have left essentials unnoticed. The broad fact, however, to which we would direct attention, is that a man of Dr. Mach's attainments should advance opinions which are so directly opposed to a great deal of the teaching of the present day. He brings fundamental modern conceptions of heat to the test and he finds them unsatisfactory. The very root of thermodynamics becomes under his hands one of the uncertainties of science. Our readers will find in the remarkable letter by Col. Basevi, which we print this week, another example of the uncertain foothold which men find in this path of science. It has often been stated that though men believe in the kinetic theory of gases, they know it is not true. Col. Basevi advances arguments which make it more difficult to believe in it than ever. On all sides we find men inquiring, thinking, revising, and on all sides upsetting received theories and notions concerning the nature of things and processes. Such inquiries are no doubt distasteful to many persons, but they mean progress so long as they are conducted in a proper spirit. Yet the student of science will do well to bear in mind the words of a very eminent lecturer of physiology. "The statements I have made to you, gentlemen, I have every reason to believe to be wholly untrue, but you must learn them, because if you do not you will not be able to pass your examinations."

### CANALISATION OF RIVERS.

When in classic days a river conducted itself in such a manner as to become a source of danger to the people and lands adjacent to its banks, its behaviour was attributed to the offended majesty of its tutelar divinity. The hydraulics of rivers are assumed to be under similar control in China even now. Although the French have a proverb, *Rien n'est sacré pour un sapeur*, and it must also be admitted that the modern engineer has no particular regard for ancient fluvial deities, yet he is not indisposed to try gentle measures when dealing with their wayward changes. As a proof that the belief in a presiding genius prevails among eastern people, may be mentioned the statement that when the first railway bridges threw their shadows over the sacred streams of Hindustan, bouquets and garlands of flowers were freely dropped from the locomotive, as an offering to the river god, into the waters below. Apart alike from ancient mythology and Hindoo superstition, there is one fact, which in connection with our subject cannot be overlooked. It is the universal consensus of hydraulic engineers that in projecting works for the improvement of rivers, the natural physical features of the watercourse should be interfered with as little as possible. It matters nothing for what especial purpose the particular works may be undertaken, whether for irrigation, drainage, prevention of floods, canalisation or water supply. That rivers resent—so to speak—the alteration or diversion of their natural beds, has been shown by more than one example in India. There are not wanting instances in which, after a new cut has been made, bridged over, and the water let in, the river in one night has returned to its former channel and breached the embankment, leaving the new waterway high and dry. It is clearly preferable—in popular language—to coax than to force a river.

While engineering works belonging and even essential to the canalisation of a river are frequently common to other improvements, the distinguishing characteristic of that operation is that it is undertaken, if not altogether, yet always in the interest of navigation. A river may be considered to be canalised when its normal condition at low water has been so altered by the carrying out of works in its channel as to permit of its navigation by boats which were previously unable to ascend it. This definition applies more particularly to the tidal compartment of a river, but if least depth be substituted for low water, it will be sufficiently correct for the upper, or river compartment proper. Some engineers regard the term canalisation as inappropriate to the improvement of rivers unless executed under certain conditions. They do not consider it applicable to the improvement of a navigable stream in which the works undertaken to guide and regulate the channel are solely of a character which will allow of its contours being preserved by the scouring action of the water. A curious example of the self-canalisation of a river was afforded some years ago through the agency of flood waters, which ultimately culminated in the establishment of a new outfall for the Vistula. An accumulation of ice, attended by a consequent damming back of the water, led to the blocking-up of the stream leading to the existing outlet. The obstruction continued to increase, until the pressure became so great as to break through a protecting embankment. The result of this "directing the great sources of power in Nature" was, contrary to what generally obtains, eminently satisfactory. It constituted a self-made "river navigation," and, as will be seen, was in every sense conducive to "the use and convenience of man." It appears that, previously to this fortuitously favourable incident, the engineers of the Government had repeatedly recommended the execution of works the very *raison d'être* of which was, with the addition of other artificial measures, to secure the accomplishment of what Nature had so beneficently effected. This felicitous though somewhat forcible method of forming a new outfall for the river enabled a long reach of it to be canalised to great advantage. Subsequently lock gates were constructed near the junction of the main stream and the self-created branch leading to the new outfall, which now fulfils the duty formerly devolving upon the old outlet—namely, that of affording a passage to the ice, which, brought down by the waters higher up stream, finds its way eventually to the sea. In a strategic point of view the works thus opportunely thrust upon the Government have been equally productive of good, as they very materially contribute to a successful defence of Dantzic in the event of its being invested by a hostile army.

The chief difference between a canal and the canalisation of a river is that whereas the former, in the strict sense of the term, is wholly artificial, the latter is not. It is, however, rare that a canal, during its entire course from one end to the other, comes under this definition. In some parts of its route it usually utilises the services of stretches of rivers canalised to render them equally navigable, and also freely avails itself of the extensive area of waterway afforded by the lakes which intersect its path. A familiar instance is afforded by the Caledonian Canal, very much out of date at the present time, which has thirty-eight miles of lake navigation. Most of the principal French canals are constructed in order to effect a junction of two separate river systems—such as the Rhône and Rhine, the Loire and the Saône, the Scheldt and the Somme, and the Seine and the Rhône. In Italy we have the Cavour Canal uniting the Po and the Tessin. In America there are canals forming a continuous waterway between individual rivers, between separate lakes, and also between lakes and rivers—as, for example, between the Potomac and the Ohio, the Delaware and the Hudson, Lake Erie and the same river, and Lake Michigan and the Illinois. Lake Ontario, in Canada, joins the St. Lawrence at Montreal; and that magnificent stream is, by similar means, placed in communication with the Ottawa. This compound system of navigation is not restricted solely to inland or fresh water canals, but extends as well to those of a maritime character. The Suez Canal has a portion of its course through the Bitter Lakes.

As a rule the chief point to be attained in the canalisation of a river is to increase the available draught of water, and in nine cases out of ten it becomes necessary to attack the bed of the stream. Something, no doubt, can be frequently accomplished by collateral operations, which consist in training, regulating, widening, and otherwise generally improving the course of the river, but it is rare that even a combination of these ameliorating measures will of themselves be effectual in producing the highest possible degree of navigability. Given a channel of a certain width, depth, and velocity of current as sufficient for the purposes of navigation required, the object, after having once constructed it, is to maintain it. In those cases in which "collateral operations," assisted solely by the natural scouring power of the stream, are sufficient to ensure the constancy of the necessary conditions, the river, although rendered navigable by these means, is not, as has been already stated, considered to be canalised in the full and distinct signification of the term. It is evident, therefore, that the canalisation of a river goes far beyond the mere control and regulation of its course and current, and simply furnishing facilities for navigation. The channel of a river, in which the bed is of rock, or of any material unattackable by erosion, or one in which all natural erosion has ceased, can be rendered navigable to a certain extent by the construction of the somewhat minor engineering works already instanced. It is true that even with these favourable conditions of a regular and normal volume of water, and with an assured stability of channel, both in dimensions and configuration, the question of floods arises, which has more immediate relation, not to the lowest, but to the highest level, at which navigation can be kept open. This constitutes one of the three vertical data to be observed by the engineer engaged in works of the description under notice. The other two are the highest flood and the lowest drought level. Unless the process of denudation, or natural erosion has ceased to take effect the bed of the river channel remains unstable, and may shift at any time in obedience to local action. Under these circumstances, it is not advisable to trust to minor works to ensure the regular navigation of the waterway, as although successful at first, they are extremely unlikely to prove of any permanent value. The only method by which the navigation of a river can be improved, under these conditions, in a substantial and durable manner, is by canalisation.

Experience has determined, although the conclusion appears a little irrational, that straight reaches, except of comparatively insignificant lengths, are not to be recommended. As a consequence, therefore, in those examples in which the original shore lines are rectilineal, or nearly so, it becomes necessary to alter them. But in adopting a different system of setting out, it is, in accordance with the principle laid down at the commencement of our article, incumbent upon the engineer to retain, as nearly as circumstances will permit, the existing conditions of the banks. The chief feature of one of the new systems introduced on the Continent consists in the abandonment of the arc of a circle and the employment of a curve increasing in curvature from the tangent points towards the middle, and increasing again from this point to the following tangent.

In addition to the construction of the locks, dams, and other necessary works, the canalisation proper of a river is always accompanied by dredging operations, frequently upon a scale of considerable magnitude. When the inequalities have been levelled and a new channel created, in order that its course should be accurately maintained, the trace of it should be set out, not by straight lines and arcs of circles, which always present more or less abrupt changes of direction, but by arcs of a curve termed by French engineers *sinusoide*. The great extent in the variation of the radius of this curve, and the continuity which it presents in this variation, has been the cause of it having been very much adopted abroad in the canalisation of rivers, and in instances where the rectification of the normal configuration of the channels was concerned. It was so employed in connection with the works attending the improvement of the river Rhone. It may be noticed that this is also the curve which would graphically represent the variations in the currents, generated under certain conditions in a single coil.

It is unnecessary to mention examples of the canalisation of rivers. Our own Mersey, Weaver, and other streams were canalised, after a fashion, more than a century and a half ago. But there is one example which we shall quote, not merely on account of its importance and magnitude, but for the practical bearing it has upon the subject of our article, and the explicitness with which it corroborates the real meaning we have attached to the title. We refer to "The Danube Regulation Works," described and illustrated in The Engineer of June and July last. Without needlessly recapitulating, it may be stated that the twofold object in view was, first, to do away with the small depth at low water; and secondly, to check the high velocities, so as ultimately to ensure free navigation through the cataracts of the Lower Danube. To accomplish this result it is intended to deepen the navigation channel through the cataracts with a bottom width of 200ft. and a depth of nearly 7ft. below the lowest drought level. During the construction of the canal through the Iron Gate this depth was increased to 10ft. The manner in which the canalisation of this portion of the Lower Danube was effected, and the machines employed in executing the different works, point out unmistakeably that, both in extent and purpose, they far exceed those ordinarily applicable to the mere training or improvement of a river.

### THE DROUGHT IN SCOTLAND.

The past month of September has been the driest experienced north of the Tweed for over a century, particularly in the West of Scotland, where the total rainfall for the month averaged only seventeen hundredths of an inch. Such abnormal dryness, in a district notorious for a too abundant rainfall at all seasons of the year, has naturally had a potent influence on the water supply. The wet weather generally prevailing during the summer has enabled the large towns to face the autumn scarcity with full reservoirs, and such places have not suffered appreciably, but smaller towns in many parts of the country have been put to considerable straits, while the numerous residential places on the Firth of Clyde were almost without exception left without potable water. From Gourock to Stranraer on the one shore, and Kilkriggan to Campbelton on the other, an acute water famine prevailed, necessitating the departure of visitors, and entailing great hardship on the natives, who were reduced to carting scanty supplies from distant lochs and streams. Nothing approaching such an universal scarcity has been experienced since these towns and villages came into existence, though in 1887, and also last year, there were periods of remarkable drought, which tested the resources of the great towns and cities severely. It appears, then, that the dry spell of last month possessed some unusual features, causing it to be specially felt by places depending on a direct hill supply for water. On turning to the records of the Ben Nevis summit observatory, we find that last month had the smallest rainfall of any month since the observatory was built in 1883. Under usual conditions the rainfall at the summit of the mountain greatly exceeds that at the sea level, but during the past month it was for the first time on record less on the summit than at the sea level. This very unusual occurrence explainable by the continuation of north and easterly winds during the whole month, at once explains the rapid failure of the water supplies of Clydeside towns. These places are usually situated at the base of a range of hills with an elevation of from fifteen hundred to two thousand feet. The waters of some streams are impounded by banking across the mouth of the glen through which it flows, a first-class water supply, equal to all ordinary requirements, being thus obtained at a very moderate expenditure. During seven months of the year the mountain stream could supply five times the water required, and even in dry weather copious and frequent showers condensed on the hill tops from the Atlantic breezes keep the supply abundant. When, however, a continuation of dry winds is experienced, so that even on the top of Ben Nevis no moisture is condensed for weeks at a time, it is evident that the system of water supply described is extremely liable to failure, unless the storage capacity is large. This, for the reasons mentioned, it seldom or never is, so that when the feeding stream dries up the stored supply is speedily exhausted. The remedy is obviously increased storage capacity, and though such a phenomenally dry September as the last is not likely to recur speedily, the absolute failure of water supply, or even its probability, is so serious a calamity that the authorities of the places which have suffered cannot afford to disregard its possibility. The case of Helensburgh, the only residential town on the Firth of Clyde which has not suffered from water famine during the recent drought, shows the advantage of sufficient storage capacity. During the remarkably dry summer of 1887, this town suffered unpleasantly from the long continued dry weather. The main feeding stream of the supply system, the Ballyvoulin Burn, dried up completely, and the one reservoir above the town, in spite of a very restricted supply to the inhabitants, threatened to give out altogether, a contingency which would have necessitated the carting of water a distance of six miles from Loch Lomond. The magnates took the lesson to heart, and on the advice of Mr. Wilson, of Greenock, trebled their reservoir capacity, with the result that at the end of last month the engineer was able to report a full three months' supply still in store.

### BRITISH MACHINERY IN RUSSIA.

According to recent Foreign-office reports, the introduction of English cotton, spinning and weaving machinery into St. Petersburg in 1893 was considerably larger than during the previous year, and extensive orders for delivery during the present year were taken by English firms. It is generally supposed by those thoroughly competent to form an opinion on the subject, that the reduction of the duty on cotton machinery under the Russo-German Commercial Treaty is not likely to increase the demand for the same, the reduction being inconsiderable. As this kind of machinery is not made in Russia, it must be imported to the extent of local requirements. Owing to the comparative lightness, the duty does not bear very heavily on it, as in the case of boilers, paper-making machinery, steam engines, &c. Although all cotton spinning machinery came as formerly from England, the Mulhausen district of Germany secured orders for sundry dyeing, printing, and finishing machinery, which used formerly to go to England. One reason for this is the lower price of German machinery, but another and more important one is that German makers are ever ready to construct or alter their machinery to suit the convenience, and often merely the caprice, of the Russian buyer whenever they can possibly do so. Several new mills for spinning combed wool were built, but the machinery for them was ordered in Alsace instead of in England. The importation of paper-making machinery, now principally German, was somewhat checked last summer by the enormous increase in the duties levied differentially, when it was of German manufacture. The outlook for the present year under the reduced duties has stimulated the importation, and there is every appearance of a great increase in it. British threshing machines continue to be those most appreciated by the Russian farmers, and the demand for sets last year was so great and sudden, that intending buyers who came to Moscow, not only were unable to make any purchases, but could not get their orders executed in England. The general conclusions are that although British machinery makers fully sustain their reputation for high-class articles, Russia and Germany secure more business than they did previously. For mill engines, Switzerland, a new and dangerous rival, is coming to the front. Millowners who formerly bought exclusively in England, placed several orders with Swiss makers, and appear well pleased with the goods supplied. Prices, freight, and duty are about the same, whether the machinery comes from England or Switzerland, but Swiss makers guarantee the consumption of steam required by their engines for the work performed, which pleases Russian buyers.

### SHIPBUILDING IN FRANCE.

The new law which increases the premium upon vessels constructed in France is said to have given a very great stimulus to the native shipbuilding industry. We referred lately to a new yard that had been established at Rouen, where enough contracts have been entered into to keep the hands employed for several months to come, and now a similar success has been achieved at Nantes, where the construction of a maritime canal, and the deepening of the port, have allowed of vessels drawing more than 6 metres of water ascending thereto. Last week the launching of the cruiser Descartes, the first war vessel constructed at Nantes, was made the occasion of a general holiday, and in the speeches which followed the ceremony the directors and other officials of the Société des Chantiers de la Loire spoke of the great possibilities that were now opened up to Nantes as a shipbuilding centre. The Descartes has a length, over all, of 96 metres, and a displacement of 4000 tons. It will be entirely completed at Nantes before proceeding to Brest, where it will receive a powerful armament. Besides this vessel the Société des Chantiers de la Loire have other vessels in hand for the marine, including the armoured coast defence vessel Valmy, the first-class battleship Massena and the cruiser d'Assas. They have also building four large sailing vessels, of which three of 4200 tons each are to be constructed for MM. Bordes, of Bordeaux. The company expects to enter into several other contracts shortly, so that the 3000 hands employed at Nantes, St. Nazaire, and St. Denis will be kept busily engaged for a long time to come. This result is considered to be all the more satisfactory in view of the exceedingly low freights, and it is thought that as these become more profitable a still further impulse will be given to the native shipbuilding industry. According to the builders this result could not possibly have been attained if foreign-made vessels continued to receive the half premium, but the owners themselves entertain the contrary opinion, as they consider that the premium hardly compensates them for the increased cost of the vessels.

## LITERATURE.

*Ueber Vorkommen und Gewinnung der nutzbaren Mineralien in der Südafrikanischen Republik — Transvaal — unter besonderer Berücksichtigung des Goldbergbaues.* By Bergrath Schmeisser. Dietrich Reimer, Berlin. 1894.

The work now before us, which is practically an account of the gold mines and other mineral industries of the Transvaal, is certainly in many respects the most valuable contribution that has yet appeared to the already ample literature devoted to this subject. Besides the importance to which its intrinsic merits entitle it, it deserves special attention from Englishmen, seeing that it is fraught with a number of instructive and incisive lessons for us, which we should do well to take to heart.

It appears that the Prussian Government, having regard to the repeatedly expressed opinions of statisticians that the gold supply of the world is rapidly falling below its requirements, resolved to send a mining engineer to the Transvaal to investigate the position and probable development of the gold production of that country. Herr Schmeisser was accordingly sent out, and the book now before us is the result of his studies. Although British interests in the Transvaal are beyond comparison, more important than German, and the ties that bind us to South Africa are far stronger and further reaching than the somewhat indirect Prussian connections with that part of the world, yet we find the German Government freely taking upon itself the duty of studying this new goldfield, whilst our Government has never even thought of such a thing, and probably never will, all our knowledge of African gold mining being due to private initiative. It is evident that the German Government does not consider that it has done its whole duty to the mining industry of the country, when a local postmaster has been appointed inspector of mines; nor does it look upon a successful political canvasser as superior to a trained scientist for the carrying out of such duties. In England, however, we do things differently, and the attitude of our Government towards mining and manufacturing industries cannot but suggest the reflection that whilst party Government has its advantages, it has drawbacks that pretty well balance them.

Not only does Herr Schmeisser's book teach us a lesson in its mode of inception; it is equally instructive in its mode of execution, and is an admirable example of German thoroughness. The first chapter is of merely general interest, giving a brief account of the geography, history, and constitution of the Transvaal. With the second chapter, the geognosy and geological description of the country are commenced. The author gives a brief account of the various formations that occur in the Transvaal, and of their relations to each other. Although necessarily still very imperfect, this sketch gives an excellent outline of the broad geological features; and though errors of detail doubtless exist, the author's general conclusions will probably be found to be correct when fuller details are available for a systematic study of the subject. Herr Schmeisser has not only utilised the observations made by others, he has contributed largely to our knowledge of Transvaal geology by his own researches.

Commencing with the lowest sedimentary formation, the Swazischists, and the gold veins contained therein, it is worth while noting that he looks upon the Sheba reef as a true reef, whilst most previous writers on this subject seem rather to have held the view that it is an altered bed. His opinion on this reef may be gathered from the following quotations: "The footwall is sharply defined, the hanging wall less so, because the deposit is more or less united to the quartzite which forms the hanging wall. Midway between the two walls, a well marked fissure like a false hanging wall traverses the entire deposit. . . . . . Fragments of the country rock from the hanging wall side are of common occurrence in the body of the vein. . . . . The mode of occurrence of the Sheba deposit, its great width, and the presence of large horses of the hanging country rock, justify the inference that this is a composite vein, that is to say, a vein formed by the simultaneous opening of several fissures within narrow limits, and the destruction of a part of the rock-masses that separated them." The various other gold districts in which veins in the Swazischists are being worked, namely, Komati, Selati, Letaba, Molotsi, Houtboschberg, Marabastad, are all dismissed in a few words, commensurate with their present trifling importance, and then the gold districts of the Kaap series of rocks are approached, the first place in which is naturally taken by the Witwatersrand deposits. Herr Schmeisser is careful to point out that these are bedded deposits, although in describing each bed, he subjoins the name of the "reef" by which it is conventionally known. The entire "reef" series is fully described, and a capital table given of the various mining companies in the order in which they are situated along the main reef. For the first time we have a really exhaustive scientific description of the constitution of the famous Witwatersrand conglomerate. According to our author these are true quartz conglomerates, the pebbles being cemented by a mass of granules of the same quartz held together by a binding material of greyish-blue or green colour when undecomposed. The quartz pebbles consist but rarely of individual crystals; they are mostly rather coarsely crystalline, rarely microcrystalline aggregates, the granules showing no definite system of co-ordination. The quartz contains but few solid inclusions, but an extraordinary number of fluid ones, arranged in approximately parallel planes, so as to give sections of the quartz a streaked appearance. The microscopic structure of these pebbles, as well as their frequently flattened outlines, point to strong mechanical action, in all probability due to pressure, the effects of which are also seen in the cementing material. This latter contains, in addition to small grains of quartz, the following minerals:—Pyrites, magnetite, zircon, rutile, muscovite, chlorite, secondary quartz, and native gold. In one specimen tourmaline was found. The pyrites, the most abundant mineral next to the quartz, is a primary constituent of the conglomerate. The gold is a secondary component, and is not of alluvial origin, as is shown by its crystalline form, and the mode of its distribution in the conglomerates—it never occurs, properly speaking, enclosed in the quartz. When it is found in the pebbles it is always in a thin fissure or seam in them. It is evident from the above synopsis that the results of this research have given data of great value in determining the probable permanence in depth of the Witwatersrand auriferous conglomerate beds. Herr Schmeisser's calculations as to the probable duration of the working of, and the amount of gold available in the best known portions of the Witwatersrand goldfields were published in the German "Reichsanzeiger" for February, 1894, and were almost immediately translated into English. The results of these calculations will probably be fresh in the memory of our readers, and we need not therefore refer to them again.

The remaining goldfields of the Kaap formation, namely, those at Klerksdorp, Vryhied, and Lydenburg are briefly described; the latter perhaps not quite so fully as their geological, apart from their industrial, importance might seem to merit. There is also a brief account of the coal seams that are worked in certain of the Karroo formations, and a mention of other mineral occurrences—notably those of silver—closes this valuable chapter.

The third chapter comprises an account of the mode of extracting the various metals and minerals. It contains a short but fairly correct history of the rise and progress of mining in the Transvaal, and an excellent summary of previous legislation on the subject and of the existing gold law. The methods of mining are next described, and then the system of stamping and gold extraction. This is perhaps the weakest portion of the whole book, as many details of importance are omitted, and a few inaccuracies have crept in. It is interesting to note that the author estimates that during 1893 there were, on an average, 1955 heads of stamps at work in the Rand, and that their average crushing capacity was three tons per head per diem. He also refers briefly to other crushing machinery, concluding his paragraph on this subject with the pregnant remark that "the Huntington mill at the Wolverdon Gold Mines near Klerksdorp only ran for two days." A few pages are devoted to an account of chlorination and of the cyanide process. The description of the latter is good, but contains nothing novel. With regard to the machinery employed on these fields, our author states:—"The whole of the colossal requirements of the Transvaal as regards machinery is supplied by English and American manufacturers; but few German manufacturers or contractors are represented in Johannesburg. Hence, English and American makers are so busy *that they cannot themselves execute the orders, but are compelled to obtain assistance from Germany*. The Buckau Machine Works were lately building a 600-horse power driving engine to the order of Messrs. Fraser and Chalmers, of Chicago, for the stamp mill of the City and Suburban Gold Mines, near Johannesburg." The italics are our own.

The work concludes with a series of valuable tables, showing the output and financial position of the various Transvaal gold mines, and with a number of maps showing the general position and features of the various goldfields.

As we have already said, this is by far the best work on the subject we have yet seen, and perhaps the only one that can be considered as a serious scientific book. There are, nevertheless, one or two points on which we are not at one with the author. We cannot, for instance, admire his inclusion of all weathered rocks within the comprehensive term of Laterite, the same name being applied indiscriminately to weathered diorite and to weathered stratified rocks. It may be convenient to call the various deposits treated by hydraulicking at Spitz Kop, Rosshill, and Lisbon, Berlyn laterite, but it is certainly not scientific, and as regards the last-named property absolutely incorrect, even with the very elastic meaning here given to the word. Again, we cannot agree in the opinion here expressed that closer concentration by mechanical means—the German system of close dressing—is beyond doubt desirable. The author ascribes its absence to the influence of American mining engineers, who, he says, are not acquainted with such accurate dressing operations in their own country. We are not concerned in defending the American as against the German system of ore dressing; on the contrary, we hold the latter to be, generally speaking, the better. But in treating gold ores, too many dressing operations must be avoided if float gold is not to be lost, and we ourselves do not look for any improvement in the treatment of tailings in this direction. Nor do we agree with the condemnation of Frue Vanners, for the reason that they make only two classes and no middlings; this may not suit the ordinary concentrator, but it is, on the contrary, precisely what the gold miner wants. He only wants two classes—clean concentrates containing all the gold, and clean tailings containing none. Experience so far is against carrying dressing operations too far in the case of gold ore, although a certain degree of sizing would no doubt be found beneficial. We rather venture to think that the attention of gold-mining engineers will be directed in the near future to the question of treating all the tailings direct as they leave the plates by some chemical process that shall remove the gold left in them after amalgamation; and we believe that such a process is quite within the bounds of engineering science.

In conclusion, it remains only to say that all engineers are greatly indebted to Herr Schmeisser for having produced such an admirable work on a subject of general interest, as well as to the German Government for having given the incentive to it, and as we are not likely to get anything of the kind done for us in this country, we hope it will not be long before the work will appear in an English dress that will make it readily accessible to the mass of English engineers who would be glad of an opportunity of studying it. It is, however, to be hoped that any English translation will be furnished with a good alphabetical index; the absence of any index at all is a very serious blemish on the present work.

*Continuous Current Dynamos and Motors.* By Frank P. Cox. New York: The W. J. Johnston Co., Ld.

*Electric Light Fitting.* By John W. Urquhart. London: Crosby Lockwood and Son.

*Electro-Magnetism and the Construction of Dynamos.* Vol. I. By D. C. Jackson. New York and London: Macmillan and Co. 1894.

The work upon dynamos by Mr. Cox is intended as an elementary treatise for students, and is really a valuable book. It deals with no particular type of machine, but is a general consideration of the laws governing the design of direct-current dynamos and motors. The book is not burdened with cuts of the external appearance of machines, but discusses the principles which underlie the design of the separate parts. It is only assumed that the reader has a knowledge of algebra and of the elements of geometry. After describing the systems of measurement and the theory of the production of current, the author proceeds to calculations appertaining to the magnetic circuit, and deals first with the determination of the induction by the methods of Gisbert Kapp and of Drs. J. and E. Hopkinson, of which the author prefers the latter method. In the following chapter, the theory of winding, losses, &c., are discussed, and important use is made throughout of the system of plotting curves to represent results.

A good feature in the book is the practical application of the principles and formulæ which have been discussed to the actual design of dynamos and motors. The author supposes the case of a 200-light dynamo required to develope 110 volts at a speed of 1500 revolutions per minute, and very clearly explains his method of calculation. The last two chapters of the book are devoted to the action of steam in an engine, which is, of course, a subject which should be known for dynamo testing. In a table of belting, in the form of an appendix, we note that the author uses the word "strain" throughout where he means "stress." The book should be of considerable interest to young draughtsmen in the offices of dynamo builders.

Mr. Jackson is the professor of electrical engineering in the University of Wisconsin, so that we are able to compare two American methods of treatment with one another. This work has been developed from the lectures delivered by the author to his classes in dynamo construction. No special machines are described or illustrated, and only continuous current types are dealt with. Alternating work will be dealt with in a subsequent volume. A knowledge of the calculus and trigonometry is required to understand parts of this work.

In his description of experimental methods for the determination of the magnetic properties of iron the author alludes to a modification of the Hopkinson apparatus made by a Mr. Burton for the laboratory of the University of Wisconsin, the magnetising coil being placed upon the yoke instead of on the test piece.

Ewing's work is followed, and the results obtained are plotted. Both this work and that of Mr. Cox are very well printed. The author pays a great deal of attention to compensation for cross turns, and alludes to a number of different designs of winding. From the point of view of the Professor, he appears to desire to sort machines into families and species, and to fit each type with its special formulæ. Perhaps it is too much to say that some Professors are interested in the various types for the sake of the pleasure of producing formulæ, but the commercial aspect of the question is distinctly absent from the greater part of the work.

Mr. Urquhart has written several books upon electrical subjects; they are descriptive works, not dealing with formula or analysis at all. No mathematical knowledge is needed to read them, and the author writes for the intelligent workman engaged in electric lighting, or training for it; he claims the book to be the notes of a practical electrician. We see that the usual allowance of breadth of belt is said to be 1in. per horse-power, for belting moving at a speed of 1000ft. per minute. This is certainly on the safe side, as few belts come up to this requirement in practice. The rule is stated to apply to belts from 3in. to 12in. in width. The brush-moving device spoken of as suggested by a Mr. R. Tatham was patented some years ago by Mr. Druitt Halpin, and we believe was used in several cases. The practical directions concerning care of the dynamo and attention to the commutator, re-wiring, &c., are well written, and the notes as to attention to alternators are very valuable to dynamo tenders. In instructions for testing the insulation of electric wiring, the author alludes only to the Wheatstone bridge method, and describes in detail the method of using the Silvertown set. This is, of course, very useful for telegraph work and cases in which a low potential will eventually be used, but it is not nearly so satisfactory, in our opinion for circuits which will be supplied from the public mains, where a magneto machine and Evershed ohmmeter are distinctly preferable.

In his chapter upon the lighting of ships the author gives some useful hints, and recommends screw socket lamps. We have often thought it strange that in the United States the screw socket should be practically the only type in use, while here the pin socket is almost the only one employed. The explanation adduced by some electricians, that screw socket holders tend to slack back from vibration, can have little point if this pattern is considered best for steamships.

## *BOOKS RECEIVED.*

*Tramways, their Construction and Working.* By D. Kinnear Clark. London: Crosby Lockwood and Son.

*Recent Cotton Mill Construction and Engineering.* By Joseph Nasmith. Manchester and London: John Heywood.

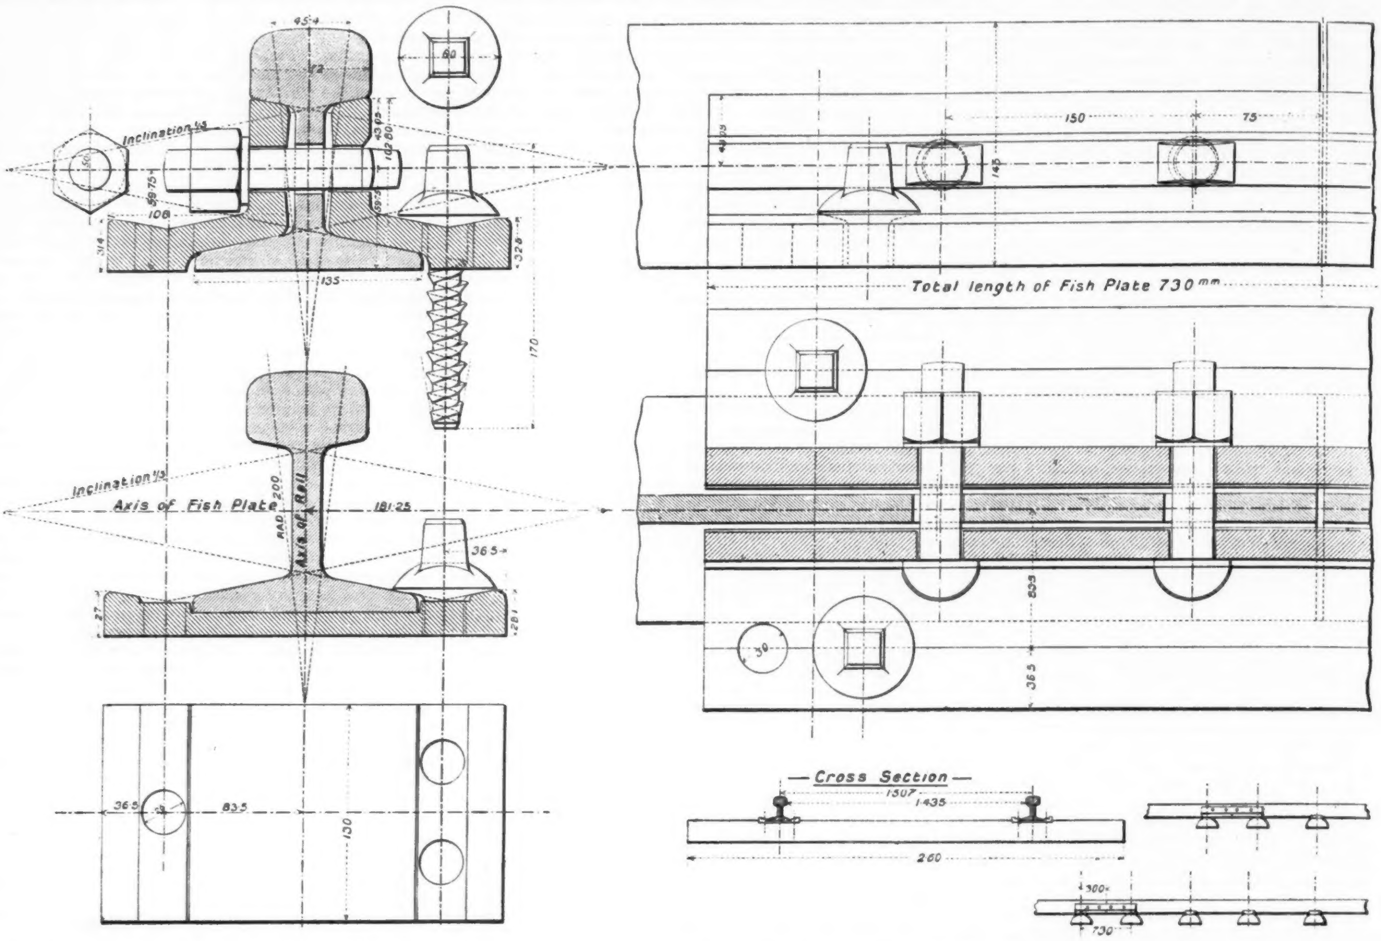
*What is Heat? A Peep into Nature's most Hidden Secrets.* By Frederick Hovenden, F.L.S., F.G.S., F.R.M.S. London: W. B. Whittingham and Company. 1894.

*Electric Light and Power.* Giving the result of practical experience in central station work. By Arthur F. Guy A.M.I.E.E. Illustrated. London: Biggs and Company.

*Electric Transmission of Energy and its Transformation, Sub-division, and Distribution.* A practical handbook. By Gisbert Kapp M. Inst. C.E. London: Whittaker and Company.

## THE LATE MR. J. H. OSBORNE, C.E.

The death is announced at his residence, Summerseat, near Philadelphia, of Mr. John Humfrey Osborne, who has been a prominent civil engineer in the United States for over half a century. He was born in Dublin, September 30th, 1818, being the second son of R. D. B. Osborne, barrister-at-law, and Lucy Caulfeild, only daughter of John Humfrey, of "Killerig," co. Carlow, and was a direct descendant of Sir Edward Osborne, of Ashford, Kent, Lord Mayor of London, 1583, and of his grandson, Thomas, first Duke of Leeds. Mr. Osborne was educated at Mr. Richard's school, Bathampton, and on leaving school travelled widely, visiting Australia among other countries. In 1839 he went to the United States, and became confidential secretary to Mr. Wirt Robinson, chief engineer of the Philadelphia and Reading Railroad. From that time he threw himself ardently into the profession of engineering, and rose to be chief assistant in 1843. Three years later he was appointed chief engineer of the Philadelphia and Reading Railway, but resigned that position later on to join with his brother, Mr. R. B. Osborne, in the construction of the Waterford and Limerick Railway. Returning to the United States in 1850, he was appointed to the Ogdensburg and Lake Champlain Railway, and the next year took charge of a portion of the construction of the Southside Railway in Virginia. From 1852-3 he was superintendent of the Richmond and Danville Railway, and on resigning that post, to become associate chief engineer and superintendent of construction of the Camden and Atlantic Railway, was presented with a massive service of plate as a mark of the affection and esteem in which he was held. After the opening of the Camden and Atlantic Railway in 1854 Mr. Osborne became its general superintendent, but resigned four years later, to take charge of the construction of the most difficult section of the Lebanon Valley Railway through the counties of Berks and Lebanon, Pennsylvania. In spite of great difficulties Mr. Osborne completed this work to the day and publicly received the congratulations and thanks of the president and board of directors. In 1858 he also rebuilt the Quakake Railway, uniting the Lehigh Valley, Black Creek branch, with the Catawissa Railway above Tamaqua, and with his brother, Mr. R. B. Osborne, made a survey for the continuance of this line into the Mahanoy coal fields. In 1873 he also undertook with Mr. R. B. Osborne an extensive barometrical survey for the Shenandoah Valley and Ohio Railway from Harrisonburg, Va., over the Great Northern and intervening mountains, crossing the Alleghanies into the Valley at the head waters of the Greenbriar River. Mr. Osborne continued from time to time to take an active part in his profession to which he was most devoted, but for the past twenty years practically lived in retirement at his country place Summerseat, between Philadelphia and New York—one of the oldest and most interesting residences in the United States. The house, built over a century and a-half ago by an English gentleman, Captain Barclay, was the headquarters of Washington before the battle of Trenton, and the rooms he occupied and in which he wrote many of his despatches are often visited for their historical associations.



CROSS SLEEPER PERMANENT WAY, BELGIAN STATE RAILWAYS

## PERMANENT WAY: BELGIAN STATE RAILWAYS.

Of the 2000 miles of line which form the system of the Belgian State Railways, 500 are called "International." There is probably no European country which has more through traffic than Belgium. Ostend has long been the rival of Calais for conveying English and American travellers to Germany and Austria; whilst Antwerp, as the chief commercial port of Central Europe, receives each year larger quantities of goods in transit for these countries. Traffic from Holland to France naturally passes through Belgium, and the railway through Luxemburg, which nearly served as as the pretext for a war between France and Prussia in 1868, has long been considered one of the main highways of Europe.

Before 1880, the rails used on all lines belonging to the Belgian Government weighed 76 lb. to the yard. The sleepers were of creosoted oak, half round, 10in. diameter, and 8ft. 6in. long, and there were ten of them to a 30ft. rail. Ordinary flat fish-plates were used, with four bolts. As the traffic became heavier, it was requisite to increase the strength of the permanent way. The section of rail was not changed, but in 1881 twelve sleepers were substituted for ten, and soon afterwards angle fish-plates, instead of flat. Meanwhile the weight of the locomotives necessary for express trains was continually augmented, till, in 1885, engines were being used in which the load on each pair of driving wheels was fifteen tons. It was then decided that the permanent way on the sections carrying international express trains would require to be completely reconstructed, and M. A. Flamache, Chief Engineer of the Belgian State Railways, was authorised to make an experiment, by re-laying two miles of the track between Antwerp and Brussels in whatever manner he thought best, using a rail which should weigh about 100 lb. per yard. He kept to the Vignolles section, but adopted a rail 5⅝in. high, 5⅜in. flange, with head 2⅞in. wide, and weighing 105 lb. per yard.

From experiments which he had been carrying on for some time, M. Flamache decided that screws were better than spikes, and that the form of screw shown in the drawing was the most suitable that he could adopt. It will be observed that the screw is cylindrical, not taper; that the pitch of the thread is ½in., which is unusually large for a screw whose diameter, measuring over the thread, is less than an inch; and that, instead of the upper and under surfaces of the thread tapering equally, the former is almost horizontal. M. Flamache's experiments led him to believe that this form of thread not only held better, but did less damage to the grain of the wood, than when both sides of the thread tapered equally. The conical shape given to the underside of the head, he also considered to be advantageous to the stability of the line. The diameter of the sleepers has been increased from 10in. to 11in., and their average distance apart is 2ft. 6in. centre to centre. This distance is diminished to 2ft. at the joints, whilst the fish-plates are 2ft. 5in. long. The rails are always vertical, and, except at the joints, there are plates between the rail and the sleeper.

Between Antwerp and Brussels the track is tolerably level; but on some parts of the system, and especially on the Brussels, Namur, Arlon, Sterpenich sections, there are inclines of 1 in 62, and even several of 1 in 55. On this branch, the weight of engine and tender is 83, and sometimes 88 tons; an increase of 40 per cent. over the weight of those formerly in use. It was calculated that a 95 lb. rail would be sufficient for these engines, but the 105 lb. was adopted to allow for rust, &c.

The first section of two miles was put down on the Brussels and Antwerp line in May, 1886. In 1888 another six miles was added to this, and as the new track was considered satisfactory, it has been substituted for the old, at the rate of 100 miles per annum. In the latter part of 1892 part of the permanent way laid down in 1886 was taken up and examined. Several of the sleepers which, as far as could be judged by external appearance, seemed the worst, were sawn through the screw hole. In all of them the thread was in a perfect condition, though it is calculated that 170,000 trains had passed over that section of the line since the new track had been laid, including fifteen express trains daily, and heavy goods trains, frequently with wheels on the brake-vans worn into flats. Altogether M. Flamache estimated that this test was equivalent to thirty years' work on any average continental line. M. Léon Bika, Chief Engineer of the Belgian State Railways, says that they continue to be thoroughly satisfied with the new road, and that the duration of the sleepers is much longer than they had expected.

## ON THE HEATING POWER OF SMOKE.

By R. R. Tatlock, F.R.S.E., F.I.C., F.C.S.

It appears to be generally understood that a large percentage of fuel is lost in the smoke which issues so abundantly from most chimneys, and random statements have been made to the effect that the loss in heating power due to this passing away of combustible matters in smoky furnace gases may reach as high as 30 per cent. of the whole. A little consideration, however, will show that the loss of any large percentage of combustible matter, and consequently of heating power, is quite out of the question. This may be proved in two ways (1) by calculation of the two sources of heating power as shown by an analysis of coal or dross used for steam raising; and (2) by actual analysis of the furnace gases for combustible solids and gases. In the following paper are given the results of these two methods of observation, the same dross being analysed and also employed as fuel in a works furnace, from which smoky gases were given off which were tested for combustible matters.

(1) The following is the analysis of the dross employed:—

| | |
|---|---|
| Gas, tar, &c. | 37·63 |
| Fixed carbon | 49·97 |
| Sulphur | ·40 |
| Ash | 2·72 |
| Water | 9·28 |
| | 100·00 |
| Heating power (practical) due to gas, tar, &c. | 1·16 |
| " " " fixed carbon | 6·49 |
| | 7·65 |

The points to be observed are the relative proportions of heating power—represented in the analysis by the number of pounds of water at 212 deg. Fah. capable of being evaporated to dryness by 1 lb. of the fuel—given out respectively by the combustion of gas, tar, &c., and by fixed carbon. These are calculated according to Playfair's well-known formula, which was practically tested on coals intended for the British Navy, and which shows that while 1 lb. of fixed carbon is capable, when burned, of evaporating 13 lb. of water at 212 deg. Fah. to dryness, 1 lb. of the gas, tar, &c., will only evaporate 3·1 lb. From these figures it appears that in this coal or dross the gas, tar, &c., only contributes 15 per cent. of the total heat given out during the combustion, and that the fixed carbon produces the remainder, or 85 per cent. In coals with less of the former ingredients and more of the latter, which is commonly the case, the proportion given out by the volatile constituents would be considerably reduced. It is thus perfectly clear that even though the whole of the volatile matters—which can alone be accountable for any loss of combustible material—escaped combustion, there could not possibly be a greater loss of heat than 15 per cent. of the whole, even in such an extreme case as this represents.

(2) An analysis was made of the furnace gases given off during the burning of the dross, of which the results are given above, with the following results:—

| | Gas very smoky. Per cent. by volume. | Gases almost free from smoke Per cent. by volume. |
|---|---|---|
| Carbonic acid | 5·0 | 3·5 |
| Carbonic oxide | None | None |
| Hydrocarbons | Trace | None |
| Nitrogen | 79·9 | 79·9 |
| Oxygen | 15·1 | 16·6 |
| | 100·00 | 100·00 |

It has been asserted that carbonic oxide is given off in considerable quantity when much smoke is being produced, but it does not appear in this case; and Hempel in his work on "Gas Analysis" comes to the conclusion that little or no combustible gases are present in furnace gases. In the volume referred to—page 205—Hempel says, "Furnace gases usually contain only carbon dioxide, oxygen, and nitrogen. All other gases are present in but very small amounts. In oft-repeated analyses the author has always found only traces of carbon monoxide, methane, and the heavy hydrocarbons." This is in complete accord with the analyses given above, and it may be taken for granted that the presence of carbonic oxide or other combustible gases in furnace gases is a most unusual occurrence. This is quite conclusive evidence that no appreciable loss of heat, even when the furnace gases are smoky, can be attributed to the passing away of the products of imperfect combustion in the gaseous form at least.

That there is loss of combustible matter in the smoke is an undoubted fact, but the quantity seems also to be greatly magnified in certain random statements. In the experiment referred to above the soot was also collected during 1½ hours with the following results:—

| | Grains per 100 cubic feet of furnace gases. |
|---|---|
| Carbonaceous matter | 30·81 |
| Ash or mineral matter | 20·65 |
| Total soot | 51·46 |

It will be observed that the soot collected consisted largely of mineral or incombustible matter. In several experiments to estimate the soot in furnace gases, similar results to these were obtained, and the average would come very close to the quoted results of this special test. To find how much carbonaceous matter was actually lost as smoke it will be necessary to know the number of cubic feet of furnace gases given off by the combustion of, say, one ton of the dross. If the percentage of carbonic acid in the furnace gases is taken at 5 per cent., the total volume of these given off from one ton dross would be about 940,000 cubic feet measured at the ordinary temperature and pressure, and this would contain 41 lb. of carbonaceous matter and 27 lb. of mineral matter. This would represent 1·83 per cent. of the volatile matters—gas, tar, &c.—given in the analysis of the dross, and if from this is now calculated the heating power according to Playfair's formula, it will only come to 0·057. This figure, compared with the practical heating power—7·75—of the dross, goes to show that the solid combustible matter of the smoke can only account for the very small percentage of 0·74 of the total heating power which can be obtained from the coal.

From the results of these experiments it is evident that the loss of combustible matters in smoke is very small indeed, and that the belief in immense loss by this cause is simply a fallacy, and is decidedly not corroborated by experiment. In adopting methods of removing the smoke nuisance it must therefore be borne in mind that there is little or no gain in burning smoke, and that other methods of dealing with the problem, such as Dulier's Smok Absorption process, ought also to receive consideration.

The Birmingham Association of Mechanical Engineers.—The opening meeting of the session of the above Association was held on Saturday last at the Grand Hotel, Colmore-row, Birmingham. The chair was taken by the president, Mr. E. Hazel, and there was a large attendance of members.

## LANCASHIRE AND YORKSHIRE RAILWAY WIDENING AT SALFORD.

To meet the demands of increased traffic, the Lancashire and Yorkshire Railway obtained parliamentary powers in 1890 for the widening of its line from Victoria Station, Manchester, to Hope-street, Salford, a distance of about a mile and a-half, and in April, 1893, a start was made with the demolition of existing house property which would require to be removed. As the route passes through a thickly-populated district, it has been found necessary to destroy about a hundred houses and shops, the old materials from which have been utilised in the foundations of the new viaducts. We give a plan showing the portions which are now being proceeded with, embracing about one-half of the projected undertaking. It will be seen that the Lancashire and Yorkshire Railway runs immediately alongside of the Manchester and Liverpool branch of the London and North-Western Railway, which latter has its terminus at the Exchange Station, while the Lancashire and Yorkshire principal station is at Victoria. Covering an area of 7½ acres, Victoria Station forms a busy nucleus of traffic; 1170 trains enter and leave it in one day, 350 of these by the lines which are now being widened. The original station of the Manchester and Leeds Railway, the forerunner of the Lancashire and Yorkshire, was at Oldham-road, the present site at Hunt's Bank being privately purchased by Mr. Sam Brooks, the vice-chairman of the company, and presented by him to the railway company in August, 1838. The station was opened on New Year's Day, 1844, and a junction with the Liverpool and Manchester line was soon effected. Between 1880 and 1884 various extensions were made, and there are now eight distinct platforms arranged in consecutive order from south to north, and dealing principally with traffic to and from the North of England and Scotland. The two chief arrival platforms are placed nearest the main approaches.

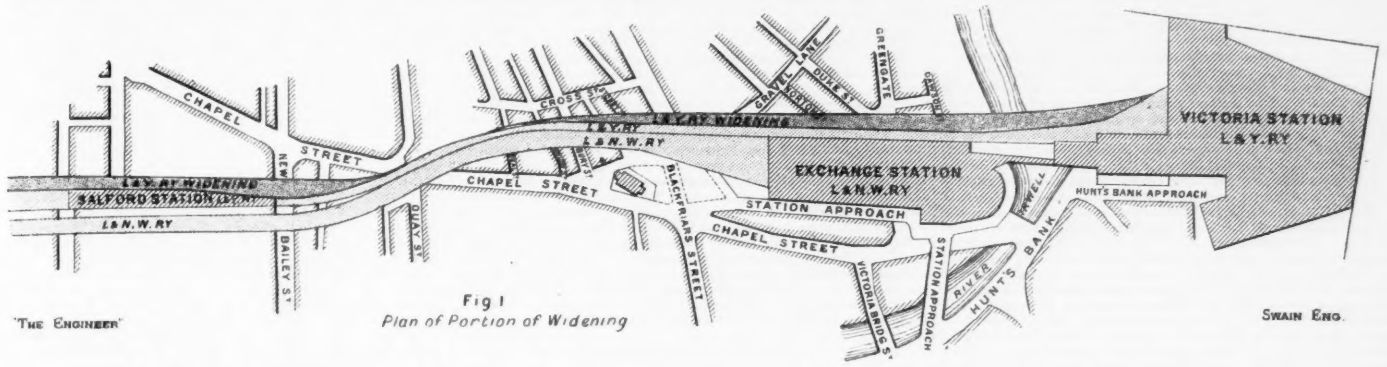


Fig 1
Plan of Portion of Widening

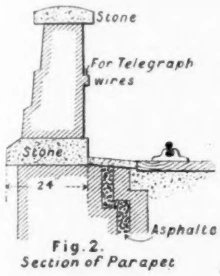

Fig. 2.
Section of Parapet

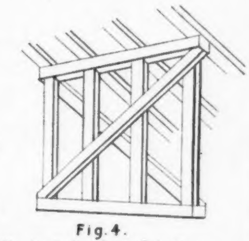

Fig. 4.
Shewing the Four Ribs of the Centre for Arch.

The present widening passes over a number of small streets, necessitating an expensive construction. Between Victoria Station and the crossing of Chapel-street, a distance of about half a mile, thirty-five brick arches have been built. They have generally a span of 28ft., with a rise of 10ft. The foundations are all carried down to the solid rock, which was found at depths varying from 20ft. to 4ft. below the surface. The piers are mostly lateral extensions of the old piers, and are built of common red bricks in lias lime mortar, or cement mortar, composed of one of cement to two of clean engine cinders. They are faced with blue bricks, and ashlar quoins are provided to the street abutments. The springers for the arches are specially made of blue brick, as recent experience has shown that in case of fire the blue brick is much less liable to damage than springers of stone, and, as most of the arches are closed in and glazed in the upper part to serve as stores, the danger of fire is one which it is necessary to guard against. The arches are constructed mostly in five half-brick rings, the two soffit rings being in blue brick, and the three outer rings in common brick. The spandrils are filled in with common brickwork, and the whole of the top surface is covered with 2in. of cement concrete and a layer of asphalte. A stone string course 24in. by 9in. runs the whole length of the face; above this the parapet wall is built, battered on the face, and having two plinth courses, as shown in Fig. 2. In order to prevent the brickwork from being damaged by drainage from the ballast of the line, a cavity is formed in the brickwork, as shown in the illustration, and run in with asphalte.

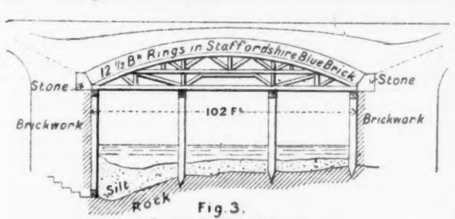

Fig. 3.
Centre for Brick Arch

There are several steel bridges included in the undertaking, the largest having a span of 63ft., and of the cantilever type. The others possess no features of special interest. One of the most interesting of the bridges is an unusually large segmental arch in brickwork carrying the railway across the river Irwell. It has a square span of 102ft., and a skew span of 105ft., with a rise in the centre of 13ft. 6in. The arch is composed of twelve half-brick rings of blue Staffordshire bricks, with springers of Derbyshire gritstone. The abutments are founded on the solid rock, which was dressed with the help of cofferdams. As the centreing alone for an arch of this size constitutes a work of some importance, it was determined to test its sufficiency by constructing a model of the centreing to scale, and applying various loads. A wooden model, one-twelfth natural size, was made, having four ribs, as shown in the Figs. 3 and 4. This was loaded with rings of blue bricks laid dry, with the interstices filled with sand; additional layers of bricks were added until thirteen rings were borne by the model without any excessive deformation, and no fears were felt that the actual centreing would not be strong enough for its work. This confidence was happily justified, and the bridge takes rank amongst the largest brick arches that have been constructed.

## RUSTLESS COATINGS FOR IRON AND STEEL.*

By M. P. Wood, New York City, Member of the Society.

(*Concluded from page* 308.)

One of the most trying situations for the protection of his work that the engineer has to deal with is in the exposure of wrought or cast iron water and gas pipes, through the cinder beds or fillings from blast furnaces, rolling mills, &c. Pitch compounds applied hot afford some measure of protection over that of the naked iron, but the creep of the pipes due to changes in the temperature of the fluids passing through them, and of the surrounding earth, the concentrated action due to the sulphur in the cinder or ashes, the porous nature of the covering over the pipe and in which it is embedded, allowing the ready access of air and moisture from the streets, ammonia, and other fumes and liquids due to the decomposition of a score or more of different bodies, all aided by the vibration caused by the passage of heavy trucks, railway trains, and kindred causes, combine to render the problem one not easy of solution. A thick puddle of good clay of a thickness all around of at least one-half the diameter of the pipe, and in case of pipes under 8in. or 10in. diameter, the thickness should be equal to the diameter of the pipe, if allowed to dry out well before covering in, gives a good protection and aids materially whatever compound is applied externally to the pipe. I do not know of any case where the pipes coated with magnetic oxide by the Bower-Barff or any other process has been tried, but it seems to the writer that if there was any situation in which the merit of the process could be demonstrated this is one, and it is not one of minor extent or importance. The rapid destruction of the wrought and cast iron mains, as well as the galvanised iron and lead service pipes of our water and gas distribution systems, by electrosis brought into action by the use of the system of pipes as a ready ground connection for our extended and fast multiplying lines of electrical service, is assuming so serious an aspect, particularly upon streets or locations where electrical railways are in use, as to call for serious consideration by all branches of the engineering fraternity for some method of protection other than now in use. So rapidly is the destruction progressing, that in many places the utter prostration of the water and gas systems may be looked for within the next decade. Pipes now affected, removed and replaced with new, but pass the corrosion further along to other and weaker points in the line, until the whole system is becoming honeycombed with points ready for failure on a little change in the ordinary working conditions. The return current from the single wire trolley system of electrical car lines appears to seek out and take for its passage back to the power house the pipe system contiguous to the line, instead of using the ground wire connections provided for it. The use of the electric motor now contributing so much to the comfort and conveniences of life in the form of electrically-driven ventilators, pumps, elevators, and other small powers, is rapidly extending the evil. The remedy, if not provided by the electric light, heat, and power companies in the form of taking better or sole care of their product from its generation to its extinguishment, will ere long be found in mulcting them for damages so heavy that the small margin now existing between the dividend point and a receiver will be wiped out.

Some experiments on a small scale of the Bower-Barff magnetic oxide application to pipes and iron exposed to electrosis action, appear to indicate its ample protective power. What it would develope upon an extended system of gas or water service remains to be tried. The iron pipes and connections, if protected by this process, would still leave the lead joints and lead service pipes exposed to attack. Cement joints might obviate part of the evil, but would render the main pipe line too rigid in withstanding changes of temperature, and expansion joints are not to be considered in pipe lines of hundreds of miles in extent. The electrical engineers as a body appear to have given this question only a sort of a happy-go-lucky, or after-me-the-deluge consideration; but the hour is not far distant when they will be walking the floor crying, "what shall we do?" instead of their water and gas brother who is now having his innings. The protective power of lime mortar and hydraulic cement to prevent corrosion in iron and steel under certain conditions has been demonstrated by centuries of actual use; yet the facts thus established are too often ignored by the engineer of to-day. We do not have to turn back many pages of the record book of success and failure to find a remarkable instance of the latter, in the utter collapse of the Bayliss patent wrought iron water pipe, that a few years ago was brought out as an indestructible, unperishable article with a hygienic annex, to take the place of cast iron pipe for water distribution. The pipe in question was made of wrought iron from $\frac{1}{16}$in. to $\frac{1}{8}$in. or more in thickness, according to the size and pressure to which it was to be subjected; formed and riveted together in the shop or worked to shape upon the ground from the sheets, by a portable lot of rolls, punches, and other tools needed, into sections about 5ft. or more in length; these sections being tapering, and if shipped were packed in nest form conveniently and cheaply so far as transportation was concerned. The tapering sections were laid in the pipe trench and lined *in situ* with hydraulic mortar, the large end of the section forming the bell for the small or spigot end, the joint being made with the cement, and the outside of the pipe was also covered with the cement mortar to the depth of an inch or more, all as far as possible at one operation, depending somewhat upon the size of the pipe, the location and the general conditions of the work, setting of the mortar, &c.

The advantages claimed were a continuous pipe from end to end, no matter what its size or length, of uniform strength, lined with a non-corrosive and protective, tasteless, and innoxious cement and guarded from external injury and corrosion from acids in the soil in which it was laid, and atmospheric influences by the same or a similar cement covering. The projectors wholly ignored the difference in the co-efficients of elasticity between the iron and cement, depending upon the integrity of the lining to protect the iron from the water; this lining once broken admitted the water pressure to the iron, the thin riveted joints of which it was impossible to caulk tight, the pressure thus reaching the external coating, which was unable to resist but a small head, cracked and flaked it off, and the destruction of the whole line of pipe followed rapidly, and as a matter of course after but a short period of service, most if not all of the lines being abandoned and relaid with cast iron pipes inside of ten years. In general no attempt was made to coat the iron with zinc or any coating, or to remove the scale of manufacture. When the pipe was thrown out of the trench finally and broken up, the outside coating came away, bringing with it the scale and oxidation under it as a porous plaster on removal takes away all over which it was spread. The connection of the house-service pipes with the main line gave no end of trouble to make and keep tight, and the whole system was a forcible illustration of the importance of those "next to nothings" that so often escape the attention of the best engineers, and bring no end of disappointment to those who are financially responsible for the introduction of the new idea.

Possibly the most extended application for a single purpose of the use of any process other than paint for the preservation of iron and steel exposed to atmospheric attack has been made at Philadelphia, Pa., in the construction of the iron work of the tower of the new City Hall, now under process of erection and nearly completed. I am indebted to Mr. F. Schumann, C.E., President of the Tacony Iron and Metal Co., Tacony, Pa., contractor for the work, for the following data. The *Scientific American* also describes and illustrates the process in the following issues, the data for which was also furnished by Mr. Schumann:—October 22nd, 1892, vol. lxvii., No. 17: "Aluminium Electro-Plating in Architecture." September 9th, 1893, vol. lxix., No. 11: "Electro-plating with Copper." This process is a double one. The first one is designed to protect the iron from rust by an electro-plating of copper of fourteen ounces per square foot of surface, and a finishing coat of an alloy of aluminium and tin of two and a-half ounces per square foot, for colour to harmonise with the stonework of the lower stories of the tower; also to prevent oxidation of the copper into a green coating of verdigris. The process was adopted as a substitute for paint, the periodical renewals of which would cost 10,000 dols. per annum, the primary coat of which was to be boiling linseed oil, in which all material was to be immersed until they had attained the temperature of the bath. The total weight of wrought and cast iron to be protected is about 500 tons, and comprises 100,000 square feet of surface, the largest single pieces being sixteen columns 27ft. long and 3ft. in diameter, weighing 10,000 lb. each. These columns received the copper coating inside as well as outside. The outside coating, being most exposed, is a double one, requiring two operations or baths, while the aluminium coat is given last as the protective coating to all beneath it. The cost of the whole process varies from forty cents per square foot to one dollar, depending upon the shape of the piece—simple plates, rods, angles, &c., costing the least, while curved pieces with large lugs, flanges with core holes, cost the most, the principal expense being the cleaning, the greatest care being necessary to ensure good work.

The capacity of the Tacony plant is about 250 square feet per twenty-four hours of from twelve to sixteen ounce per square foot coating; though some recent improvements by Mr. J. D. Darling, manager of the plating works, has nearly doubled the capacity of the plant, and avoids the trouble from "spit holes," blow holes and stodgy places, that give a great deal of trouble to search out and *solder up*. The electro-plating covering, in these cases, evidently follows the peculiarities of galvanising, where the smallest needle-hole will be coated, but will not fill up the crevice. The manipulation to apply the process necessarily varies with the shape and size of the piece. Suitable cranes, trolleys, hoisting gear, trucks, &c., being provided to handle one of the large columns referred to, the operation of coating it is as follows:—The column is first immersed in a tank containing a strong solution of caustic soda, heated by a steam coil, and is boiled a number of hours to remove all the grease and oil due to the machining process. It is then removed and thoroughly washed in water from a hose, then placed in a second tank and pickled with diluted sulphuric acid until all rust and scale are dissolved and loosened, then thoroughly cleaned with steel brushes and water and goes to the third tank containing the cyanide plating solution, and receives its first coating of copper. It is then removed from the bath and transferred to another tank and given a coating of paraffine wax *inside*, thence to the fourth tank containing an ordinary copper-plating solution, where it receives a heavy coating of copper, about sixteen ounces to the square foot of surface. The paraffin is then boiled off and the column enters the sixth or aluminium tank and receives a heavy deposit of aluminium, two to three ounces per square foot. It is then well washed with pure water and is ready for erection. The columns and other pieces are brought into the electric circuit by wires passing around them like slings, and attached to a conducting brass bar over the tank. In the cyanide tank a current density of 3 ampères per square foot is employed; in the acid tank, 10 ampères; and in the aluminium tank 8 ampères. Separate dynamos for the several tanks are necessary, the developments being 1000 ampères at 6 volts, 2000 ampères at 8 volts, and 4000 at 2½ volts.

Mr. Darling's improvements in the acid solutions enable copper to be deposited at the rate of twenty to twenty-five ounces per square foot in twenty-four hours, that is as malleable and almost as smooth as rolled copper; and copper deposits one-eighth of an inch thick, or ten pounds per square foot, have been made in twenty-four hours. For rolled sheet iron and steel, and in rods and shapes where the surface is free from sand-holes, eight to ten ounces of copper per square foot of surface will be sufficient, while on rough cast iron or steel work fourteen to sixteen ounces will be required. These amounts are greatly in excess of those given in books treating on electro-plating, but practical experience shows that the above amounts are necessary to give a protection that will prevent any appearance of rust, and will last as long as the structure will stand. For inside work when the plating is used more for effect than as a protection, zinc, tin, or aluminium is added to the copper bath to give a bronze appearance, and a coat of two or three ounces to the square foot will suffice. The new Bourse building, to be erected in Philadelphia, will have examples of both kinds of plating. The outside ironwork, windows frames, &c., will have a heavy protective coat of copper, while the inside work will be electro-bronzed.

---

* Presented at the Montreal meeting, June, 1894, of the American Society of Mechanical Engineers.

In France, when copper plating to protect iron was first used, the copper was not deposited directly on the iron, but on a coating of varnish, rendered conducting with plumbago or powdered copper, applied to the iron surface and allowed to dry. This was done to avoid the difficulties of cleaning the cast iron and the use of two solutions in depositing the copper; as the article, after the varnish was dry and the plumbago applied, was placed directly in the acid solution. This method gives a coating that is not firmly attached, and is liable to be torn off by mechanical injury. The lamp-posts of Paris and the beautiful fountains of the Place de la Concorde and the Place Louvois are examples of this method. The method used in America deposits the copper directly on the iron, and the article so plated may be bent and twisted into any shape without detaching the copper deposit. As it is often asserted that aluminium cannot be deposited from an aqueous solution, the following information, furnished by Mr. Darling, may prove of interest:—"Although aluminium is generally credited with indestructible qualities, and high resistance to corrosion, it has but few qualities that would make it advantageous as an electro deposit upon other metals; for while in a massive state it resists atmospheric action and retains a certain brightness for a long time, when it is deposited electrically from an aqueous solution, which deposit is of necessity of a more or less porous nature, it soon tarnishes and assumes a dull, bluish-white colour, when exposed to the direct action of the elements. But for a protective coat, say for copper, for which use it is used on the city hall tower, it answers very well, as the slight superficial oxidation that takes place protects the metal underneath from further attack, and the neutral colour that it assumes harmonises well with the stone work of the tower. Aluminium is no doubt more difficult to deposit than any other of the common metals. This is because of the high voltage necessary to decompose aqueous aluminium solutions, and the tendency to redissolve after being deposited. We have not got the thermal data required to calculate the potential difference or electro-motive force necessary to decompose the different aqueous solutions of aluminium, but reasoning from analogy, it must be several volts in each case, and as water requires only a minimum electro-motive force of 1·5 volts to decompose it, it would seem at first glance that a compound which requires over two volts for its decomposition in aqueous solution would involve the decomposition of the water, and therefore would be impossible. But in reality this is not so, as may be seen in the case of the caustic soda, which requires over two volts. Yet sodium may be obtained by its electrosis if mercury be present to absorb it and protect it from the water. The fact is, that when two substances are present requiring different electro-motive force to compose them, if the electro-motive force is high enough to decompose the higher compound, the current is divided between them in some ratio decomposing them both, and I find by using a solution of aluminium that has but a slight dissolving effect on aluminium, with a density of current of eight ampères to the square foot, with a sufficient high voltage—6½ to 7—aluminium can be deposited on the cathode at the rate of one gramme per hour per square foot, in a reguline state, and with higher currents it can be deposited much quicker, but it will be in a pulverulent state, which does not adhere."

Recent improvements in this process form the basis of a patent for a proposed use of electro-copper plating for the protection of ships' bottoms applied quickly and cheaply in sections, by means of movable and portable baths, the deposits overlapping each other, the entire hull being thus treated during construction, or it may be applied to vessels already built. How effectual this application for the purpose named may prove is a matter of some doubt-owing to the difficulty of thoroughly cleaning the surfaces to be coated, and which appears to be an indispensable condition for success. The irregular contour of the immersed parts of the ship being plated *in situ*, as well as the porous nature of the copper deposit requiring a heavier coating than is absolutely necessary for protection, and whether some insulating or protective compound interposed between the copper and the metal of the ship will be required to prevent electrical action, all are questions to be settled by the slow test of time, which does so much to upset the best laid plans of mice and men. If effectual, the cost of application at even the highest price named by the Tacony people, one dollar per square foot of surface, would be small hindrance to its general adoption, it requiring only about 80,000 dols. to coat our largest war vessel on its inside surfaces, as well as the outside surfaces, joints in the armour, and all places not of ready access for the application of paint compounds.

*Japanese lacquer.*—The adaptableness of this natural vegetable product to the preservation of metallic surfaces, as well as those of wood, paper, and other fibrous bodies, has never received the attention of engineers that the industrial importance of this method of coating and protecting surfaces demands. The general idea that its application is one of art, and is only adaptable to *bric-à-brac*, is wholly erroneous. The Japanese use it for an infinite variety of purposes—acid tanks, coating the keels of ships, highly finished coach and decorative panels, and articles for domestic use, resisting hot water, soap, and alkaline solutions. It may be truly said that were it not for the bamboo and lacquer trees, life for the Japanese would hardly be worth living. There is no reason why the lacquer tree should not thrive in this country. Its sap, which is used as the material for all lacquer work, is a natural essence, and vastly superior to any varnishes used here. Unlike even copal, which is an artificial mixture of resin, fatty oils and turpentine, Japanese lacquer is a ready-made product of nature that hardens into a mirror-like smoothness, never splits nor cracks, and is of great durability. The art lacquer work of Japan is essentially individual, and ought not to be treated as an undistinguishable whole. The superiority of the art work is due not only to the special merit of the material, but also to the care and skill shown by the Japanese in the manipulation of it. There is as wide a distinction between the ordinary lacquer tray, or cabinet of commerce, and the exquisite lacs of the great Japanese artists as between a theatrical poster and a canvas of Raphael. Each of the great masters of lacquer has created a style of his own, and has founded a school of which the traditions have been kept alive by his successors for centuries. At the Centennial Exhibition of 1876, in the Japanese department, there were exhibited plates, pans, &c., evidently of a common quality of lacquer used by sailors and others for domestic purposes; also some samples of a finer grade in trays and cabinet work that had been sunk in the sea over fifty years, and though covered with barnacles and other marine growths, were practically unharmed, so perfectly had they been protected by the lacquer. It seems almost incredible that so valuable an article that can be produced as cheaply as maple sap has remained comparatively unknown in this country and Europe, at least so far as applying it to the palpable protective purpose that nature evidently designed it to be used for.

In conclusion, the whole question of how best to protect iron and steel from corrosion in all the varying conditions that the wants and usages of to-day demand, seems to resolve itself into a category of Don'ts, as the best method of answering it, to wit:—

Don't use anything but common iron. Don't have any scale on that. Don't use anything but the best iron and steel. Don't polish those. Don't paint it with anything but pure linseed oil and oxide of lead or graphite paints. Don't let the air get to it if it is damp. Don't keep it from the air if the air is pure and dry. Don't let sea air, sea water, acidulated or sulphurous, ammonial or other fumes and liquids have access to it. Don't think it unnecessary to protect it in any case, because swords, armour, and other bright articles of iron and steel have been found uninjured by rust after an exposure of over 500 years with no other protection than that afforded by the closed room in which they were placed. Don't think your own product would not under the same conditions last as long as the piece of iron that was walled into one of the burial chambers of the Pyramid, 3000 years ago. Don't put it into any location where it cannot be inspected and its true condition ascertained at any time, by anybody, your successor in the trust not excepted. Don't think that magnetic oxide, electro-plating, enamelling, or any other method of protection, will take the place of constant inspection, even if the coating is fired on by a Columbiad. Don't imagine because Cleopatra's Needle has had to have a coating of wax to protect it, that it is not a good material to apply to other substances than granite. Don't let the cost and interest accounts be the governing factors in the case of protecting any metal superstructure on whose continuity and strength human life and safety depends. The old story of "for want of a nail the shoe was cast, the horse disabled, a battle and kingdom lost," finds too many parallels in the engineering practice of to-day, until in some cases we seem to need protection from the engineer quite as much as from the decay of the materials in which he experiments. Don't imagine that Macaulay's New Zealander, who has sketched the ruins of England's power and greatness, and has come to the New World to see how we have fared from the gnawing teeth of time, will not recognise amidst the ruins of Our Statue of Liberty, Brooklyn Bridge and other monuments of our progress; the ominous streaks and strains due to the corrosion, not only of iron and steel, but that of the better class of metals, and will exclaim, "We are wiser in our generation, and fear not, and can control these forces that like the Arch. slumber not, nor sleep."

## LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### THE KINETIC THEORY OF GASES.—MAXIMUM MOLECULAR VELOCITY.

Sir,—According to the kinetic theory of gases, as at present understood, the velocities of the molecules of a gas vary from nothing to velocities inconceivably great. On this point, as least, all writers on the subject are unanimous. Maxwell's statement of the above theory is as follows ("Theory of Heat," page 316):—"It appears, then, that of the molecules composing the system some are moving very slowly, a very few are moving with enormous velocities, and the greater number with intermediate velocities." Two questions are naturally suggested by the foregoing statement, viz.:—(1) What is the meaning of the words "very few"; and (2) What is the limit, if any, to the velocity which may be acquired by a molecule?

Confining our attention in the first place to the latter question, imagine a cubic inch of gas at any given pressure and temperature to be isolated in a vessel of that capacity. Now, if all but one of the molecules contained in that cubic inch could by any possibility be brought to rest by their mutual collisions, then, by the law of conservation of energy, the total energy of all the molecules would be concentrated in this single one, and its velocity would become $\bar{v}\sqrt{n}$, in which expression $\bar{v}$ is the mean velocity of the molecules and $n$ their number. Now a cubic inch of hydrogen at 0 deg. C. and at atmospheric pressure is supposed to contain something like three hundred million million millions of molecules ($3 \times 10^{20}$) and the velocity of mean square is said to be about 6000ft., or rather more than a mile per second. From this it is easy to calculate that the velocity of this single molecule, if hydrogen is the gas selected, would be considerably more than seventeen thousand million miles a second, or more than eighty-five thousand times the velocity of light. If air instead of hydrogen had been selected for our illustration, the velocity of the single molecule would still have been, roughly speaking, twenty-one thousand times the velocity of light. Enormously great as is this velocity, yet according to the present theory, unless some qualification be introduced, it is not impossible, and indeed far higher velocities than this may very fairly be supposed to exist in an enormous body of gas like that of our atmosphere. Consider, for example, a thousand cubic yards of air, which is only a small volume when compared with the entire volume of the atmosphere. One thousand cubic yards contain 46,656,000 cubic inches. Hence in a volume of air of this magnitude, if only one molecule in every 46,656,000 lost all its velocity in the manner described, the mean velocity of all the others save one remaining unchanged, it would be quite possible, and in fact necessary, for that one molecule to have the enormous velocity above mentioned.

We will now pass on to consider these enormously high molecular velocities from another point of view, viz., that of the kinetic energy they represent. This is rendered necessary, since Lord Kelvin and others have demonstrated that molecules cannot be considered inconceivably small. A molecule moving with half or a quarter, or even with a much smaller fraction of the velocity given above must be considered as a missile having a measurable quantity of kinetic energy or stored-up work in it. The kinetic energy contained in a cubic inch of air at standard pressure and temperature, neglecting for the present the internal energy of the molecules, is, according to the usual estimate, about 1·8 foot-pounds. If the whole of this energy were to be concentrated in one molecule, as would happen if it were moving with the velocity above mentioned, it is curious to reflect on what the probable result of an impact from such a missile might be on the human frame, for example. Imagine the point to be broken off a needle and to be made to strike with the above-named energy. If the point weighed a quarter of a grain its velocity would be about 1800ft. a second. It is impossible to doubt that such a missile would penetrate a considerable distance into one's body, probably passing through the flesh and bone and whatever else came in its way. But a molecule of gas is far better adapted for penetration than even the point of a needle. For it is the concentration of energy on a very small surface, combined with hardness, that causes a needle point to penetrate with such facility. But the diameter of a molecule is quite insignificant when compared with that of the finest pointed needle; and hardness is one of the predicated characteristics of gaseous molecules. Can it be, as Sir Lucius O'Trigger is made to remark in "The Rivals," that "a ball or two may pass clean through your body and never do any harm at all"? Is it possible that one of these rapid-moving molecules may pierce through and through the whole length of a nerve without causing one the least inconvenience, even without our being aware that anything had happened, although the slightest touch of the same nerve by anything else would cause acute pain? If these questions can be answered in the affirmative, what are we to think of the effect of impact from such missiles on inanimate objects—the glass windows of our houses, for example, or the pictures on our walls? The mere framing of such questions, arising as they do of necessity from the kinetic theory of gases, should be sufficient to make one hesitate to admit its truth without some modification of a nature to render the existence of these high velocities either impossible or, at the very least, extremely improbable.

So far only the translational energy of the molecules has been considered. When, however, the vibratory energy of the molecules is also taken into account, the result is still more unfavourable to the theory. Clausius supposes that the vibratory energy of a molecule is proportional to its energy of translation. In the case of air the ratio is said to be 0 634—Maxwell's "Heat," page 327. But as I have already pointed out in a former letter—June 22nd, 1894, page 542—the vibratory energy of a molecule can be nothing else but its sensible heat or temperature. Hence molecules moving with the enormous velocity we have been considering must have a temperature many million times that of one standard temperature. Now it is well known that a mere spark will cause an explosion in a mixture of hydrogen and oxygen. The absolute temperature of such a spark, say, at red heat, or about 1100 deg. C., would be rather less than five times that of standard temperature. Now a molecule moving with rather more than double the mean velocity to a temperature of 0 deg. C., and atmospheric pressure, would have a temperature of about 1100 deg. C., and consequently whenever a molecule attained this velocity in a mixture of hydrogen and oxygen an explosion must inevitably take place. But such velocities as these must occur frequently in even very small volumes of gas; hence, under these conditions, spontaneous explosions must occur immediately gases of this nature are mixed. But this we know is contrary to experience. From considering explosions of gases, one's thoughts naturally turn to gunpowder and other explosives of a similar nature, the safe storage of which would be rendered quite impossible under such conditions. Enough has been said to show that there are strong chemical reasons for supposing that there must be a limit, and that by no means an extensive one, to the possible variations of molecular velocities above their mean value at 0 deg. C. But here at once we are confronted with a fresh difficulty: for if any variation at all is possible, that is, if on a collision occurring between two molecules, it is possible for the molecule moving with the greater velocity to have that velocity increased, what is to prevent this occurring again and again and so occasionally, comparatively speaking, giving rise to velocities inconceivably great? It seems to me that only one solution to this problem is possible, and that, in one word, is "dissociation." It may, however, be urged that a gaseous explosion is simply dissociation followed by recombination. That is certainly true, but it does not follow that the dissociation of the atoms of *a single molecule* of a mixture of explosive gases is necessarily followed by an explosion. It is obvious, for example, in the case of oxygen and hydrogen that at least one molecule of each gas in proximity to each other must have its atoms separated before two atoms of hydrogen can combine with one of oxygen.

If we suppose an explosion in a mixture of gases to spread from the atoms of dissociated molecules impinging against other molecules, causing these to be dissociated in their turn and so on, then it is evident that to start the explosion the dissociated atoms must have a sufficiently high velocity given to them in some way or other for the purpose, and this necessary velocity may be considerably higher than that caused by what may be termed the ordinary velocity of dissociation due to molecular collisions at ordinary temperatures. Considering this latter kind only, as no loss of energy admissible, the transational energy of dissociated atoms must be equal to the combined kinetic and vibratory energies of the molecule immediately before dissociation takes place. But this will be modified by the mutual attraction of the atoms tending to convert the translatory into potential energy, which will, of course, in its turn be available for reconversion into kinetic energy when favourable conditions occur.

If this view of the subject is correct a certain percentage of the total energy in a volume of gas must be always potential. Again, if the velocity of gas molecules is limited in the manner described, it at once accounts for the well-known fact that air or other so-called permanent gas cannot be made experimentally to radiate any light whatsoever when heated. Finally it would seem, if this theory is correct, that in a mixture of explosive gases, such as hydrogen and oxygen, a very slow combination might take place between them without any explosion occurring, the combination being so extremely slow as not to be observable, except in trials extending over long periods of time.

### LABOUR AND LUXURIES.

Sir,—Your correspondent "R. G. B." has yet to learn the very elements of political economy. In his letter of the 2nd instant he puts words into my mouth which I have not used, and mixes up ethics and morals with political economy. Now political economy knows nothing of morals. It takes no account of them in any way. Whether a Government clerk or any one else is morally right or morally wrong in spending a sovereign on a bouquet is a question which I have no desire to discuss; whether a man who does not work ought to have any money, or be left to starve, is also a question that is totally outside my contention. What remains, if we eliminate such considerations is pure political economy, and with that only in the first instance, at all events, will I deal.

I have never said that the wearer of a bouquet was a "benefactor to a whole army of bricklayers, carpenters, glaziers, flower girls, &c." There is no such word as "benefactor" in political economy. What I did say was, that so long as a sovereign was spent, it was a matter of no importance on what it was spent; whether the men were employed in making a sovereign's worth of cartridges, or a sovereign's worth of flowers, mattered nothing to those getting the sovereign; the result was the same.

The error into which "R. G. B." has fallen is a very common one. It is embalmed in socialist ethics. It is the assumption that absolute property can be possessed in money by anyone. The exceptions to the fact that it cannot are extremly few. A miser who buries sovereigns in a hole is an exception, but I do not think we need trouble ourselves with this gentleman. In the matter of money we are all distributors, and the most that can be said is that whoever holds money has, for the time being, the power of saying into what channels it shall flow. Thus, for example, our typical Government clerk, possessed of a sovereign, may decide to distribute it among gardeners; or he may prefer to distribute it among wine growers; or he may devote it to the farmers by buying meat and bread, or to the miners by buying coal. In any or either case the result is the same; the money has been distributed, and has to use words in a well-understood sense, given employment.

Let us take two men—one of these has one hundred pounds a-year, the other has one hundred thousand. The first distributes his money wholly among farmers, bricklayers, carpenters, tailors, &c. The second has a larger range, and distributes his money besides among coachbuilders, horse-breeders, florists, &c. The result to the community in the end is better than it would have been if the £100,000 had been spent by 1000 individuals with £100 each, because employment is given over a much wider range. I do not think it is necessary to dwell on this point at all. If "R. G. B." were right, luxuries so called should not be produced under any circumstances. I suppose he will not go so far as to say this, but if he once admits that a luxury may be produced and paid for then he concedes my whole case, which is, that so far as the worker is concerned it matters nothing what he produces. The result to him is gold in some form or other. Whether the world at large would or would not be better without certain so-called luxuries is a very wide question; that I am not called upon to discuss. I have heard it said that enormous sums are wasted on growing tea, and on silk. To the political economist, however, there is really no such thing as waste in the expenditure of gold. The spender may not get an adequate return for it, but the gold will do its work in the world, no matter by whom it is spent.

Your correspondent writes, "For the sake of our argument, let us assume a more extreme case, namely, that of a millionaire who has got his money by cornering pork, wheat, or cotton, and who gives a smart function at his West End house, in which in the course of an evening flowers are consumed to the extent of £1500. Let this sum be taken as representing the labour of thirty men—in the shape of the aforesaid bricklayers, carpenters, glaziers, &c.—for one year at 20s. per week. Then what really happens is that these thirty men have to do a year's work in order to get back from your millionaire the £1500 which he took out of the pockets of the public when he cornered his pork and raised the price on them, and to obtain which he not only did nothing in return towards assisting in the production of the commodities of which he is a general consumer, but actually taxed the public."

I have ventured to quote him at length, because it would not be easy to select a better example of the confusion of mind which exists among many worthy and excellent people on the subject of value. In the first place, I may point out that your correspondent scarcely knows what "making a corner in pork" is. He is evidently unaware of the fact that, generally speaking, the pork cornered never had any existence at all. This cornering business, as practised in Chicago, for instance, is purely gambling. It means nothing more than bulling and bearing the market; practically, it is betting that pork will be such and such a price on such and such a day, and settling means paying differences. But, for the sake of argument, I will admit that a man attempts to make a real corner in pork. To do this he must buy pigs, and to get all the pigs into his own hands he must pay more for them than his neighbours. The result is, of course, that he distributes more gold among the farmers than they would otherwise have got, and the most that can be said is that he has benefited the farmer at the expense of "the public," whatever that may mean. But this only for the moment. The farmer now having more money than he had before, proceeds at once to buy extra boots, or hats, or ploughs. In the end the result is just the same as though no corner had been made. In fact, all political economists know that it would pass the wit of man to devise a scheme by which one section or individual of a community is benefited without other sections sharing in the good. Surely, for instance, "R. G. B." will admit that cheap coal is a good thing. The miner suffers on the one hand, but on the other he is a direct gainer. His wages may be less, but the necessaries of life are all cheapened and made more plentiful, and the whole community is better off.

Let me quote one passage more:—"There is no escaping from the fact that since commodities, be they flowers, carriages, dress, or what not, are only produced by labour, those who consume them without assisting in the production—directly or indirectly—do so entirely at the expense in labour of those who produce them; and, in proportion as our social system permits of wealth being accumulated without equivalent labour, in precisely the same proportion is the labour of the working classes increased beyond what is requisite to produce the commodities they themselves consume, the balance between what they consume and what they produce going to the idle; this being the reason why idleness and luxury are invariably found side by side with poverty and overwork."

We have here something so vague and intangible that it is difficult quite to understand what "R. G. B." means. I do not quite know whether it is ethics or political economy. If it is the latter the deductions drawn are entirely wrong. No man works for another, that is one fallacy. He always works for himself, unless indeed he is a slave. The miner does not hew coal for me, he hews it that he may get gold to spend on himself and his family. The second fallacy is that every man who spends should give in labour the precise equivalent of what he spends. This fallacy comes of overlooking the part played as distributor by so many. Let us return to our bouquet, and ask ourselves two questions. First, is it right or wrong in a politico-economical way to grow flowers? Secondly, suppose that our Government clerk made for himself in his leisure hours a greenhouse, did all the bricklaying, painting, &c., and grew his own flowers, would he have done better to the community at large than he did by buying the flowers?

In this case he would have a sovereign in his pocket. If he buried it then it is clear that the growing of the flowers by himself would be a distinct injury to a number of his fellow-men. If he did not bury it, but spent it, say, on a pair of boots, would the community really be better off than it actually was when the money was spent on flowers?

Possibly it may be comforting to your correspondent to know that I am myself not a millionaire; on the contrary, I have to work in order that I and my family may live. Should he take up his pen again, is it too much to expect that he will so place his ideas on paper that we may know precisely what he wants to convey? I am still terribly puzzled to know what he means by the "public out of whose pockets, &c." Again, will he explain how the labour of the very few rich men who do no work would improve the lot of those who do work? Would the match girls at the East End of London be better off if all the girls at the West End spent their days in making matches?

Shall I be considered rude if I recommend "R. G. B." a severe course of Smith, Ricardo, and Mill before he writes again?

October 8th. Y. X.

---

Sir,—Will "R. G. B." explain what he means by labour? If he had had any experience of life in Chicago he would not talk so glibly about cornering pork. The mental and bodily work done by the man—or, rather, by the men—who make, or attempt to make, a corner in anything is incredible. The anxiety, the excitement, the wear and tear are so tremendous that if labour deserves payment under any circumstances, the pork man ought to win a fortune. Americus.

The Langham, October 8th.

### GOVERNING ELECTRIC LIGHT ENGINES.

Sir,—Is it not the case that where high-speed direct coupled engines have been adopted, that the space occupied is of paramount importance, and quite apart from other considerations would determine the use of that type? No doubt high rotative speed conduces to good governing, but there are other types which find a large use, and in which first-class governing is equally essential.

In suggesting the use of the "hit-and-miss" type of governor, I think that both yourself and Mr. Robinson have overlooked some essential features of "alternator" driving, especially when the machine is one of high periodicity. In such cases to secure good parallel running, it is essential that the speed of all the alternators having the same number of field poles should be identical, and that the similar poles should occupy the same position with reference to the armature coils in each machine. Should one alternator's phase lag or advance with reference to the others, then a synchronising current will pass tending to quicken or slow the particular machine. A heavy fly-wheel, whilst tending to prevent changes of speed, would increase the difficulty of parallel running, because it would introduce a larger moment of inertia that the synchronising currents will have to overcome; unless, of course, the fly-wheel is of such enormous size and weight that the effect of variations of crank effort on speed is entirely nullified. If it is not, then although the two machines may give the same mean volts, unless the engines as well as the alternators are in phase, a larger or smaller synchronising current will pass between them at different points on the crank path.

Does not this point to two systems of governing each the best for an alternating station?

1. In a station having its units all of the same size. The governors on each unit to be as sensitive as practicable, and to be of sufficient power to control the steam on all the units in a group, and the other governors being disconnected thus one unit would be the "master" unit, the cranks being brought into unison and the loads adjusted by hand.

2. In a station having units of varying size, all the governors to be of the greatest sensitiveness possible, so as to control the speed closely when running separately, but having means by which they can be at will rendered sluggish. Then one governor, preferably on the largest unit, would be left sensitive, and the control of the fine adjustment of the station would be by the largest unit.

Of course I am assuming in case 2 that the rotative speed varies with the size of each unit, but from this point of view does it not appear that in any alternating station the speed of each unit should be the same irrespective of its capacity?

In short, I think that the governing arrangements of any particular station, especially if alternating, should be considered with reference to the whole plant as far as and including the switchboard arrangements.

Perfect governing of an alternating station would consist then not merely in the maintenance of constant or similar speed of each unit, but also in the maintenance of simultaneous and equal impulses on each alternator. Would not the system of group control by one central governor enable alternators to be driven in parallel by gas engines? G. T. P.

October 8th.

---

Sir,—We have read with considerable interest your article upon "Governing Electric Light Engines," and agree in the main with the conclusions you have arrived at, especially your statement that "what appears to be needed is a governor which the moment the speed drops or rises—say 1 per cent.—will open the throttle valve full or shut it absolutely, and will then by a series of very rapid alterations or oscillations, open and close it through smaller and smaller arcs, until the new position suited to the load has been attained."

We beg to state that these conditions are perfectly fulfilled by the "Richardson Electric Regulator," which has been used for some years, and that it will fully open the valve, or entirely close it, before there has been any change in speed of the engine, as it acts simultaneously with the turning on or shutting off of the lamps. These advantages cannot be obtained with any kind of mechanical governor, which must act after the change in speed has taken place. With the electric governor, it is also quite easy to run the engine faster with a heavy load than with a light one, its speed changing directly with the load, as it is increased or decreased. It can equally well, however, be used for maintaining a constant speed, if a constant speed is required by the dynamo, in order to maintain a constant current, or constant electro-motive force. This electrical governor is applicable to throttle valves for small engines, and to automatic expansion gear of large engines working with a current not exceeding that required for a 20-candle power lamp. Your suggestion of a piston driven by an engine producing hydraulic pressure, and working a throttle valve or automatic gear, was tried by us many years ago; but though it acted fairly well with slight changes of load, and could produce a constant speed of engine, it was much too slow in its action for great changes. Robey and Co., Limited.

Lincoln, October 5th.

### COLONIAL LOCOMOTIVES.

Sir,—As a locomotive contractor I have read with interest the leading article in your issue of September 28th on "Colonial Locomotives," the general tendency of which appears to be to show that the American knows better what class of engine to supply to Colonial roads than the English contractor. But, Sir, is it not the case that American contractors are allowed a very much freer hand in this matter than Englishmen?

Speaking from my own somewhat large experience, I can say that a Colonial road of any magnitude almost invariably retains a consulting engineer, who issues the detail specification and very generally the drawings of the engines which he may require, and in any case certainly retains the entire control of testing the material, passing the drawings, &c. In other words, the contractor has to do as he is told, and if the latter does venture to point out that in his opinion some modification should be made, he is apt to be told, of course in a most polite manner, to "mind his own business, and not pretend to know better than the consulting engineer." For example, you call special attention to the flexibility of the bearing springs which the Americans use suspended on compensating levers. It is absolutely useless to put in flexible springs and compensating beams when the play of the axle-box in the guides is limited and rigidly laid down, as it generally is by the specification. It is well known that the vertical play of the axle-boxes allowed by American builders is very much in excess of usual English practice; yet it is very rarely indeed that I have ever been permitted to alter a specification in this respect, though I know perfectly well that with a small amount of play, and therefore stiff springs, the engine is sure to ride rough on a bad road.

I believe that were the average English locomotive contractor allowed as free a hand as his American cousin, our Colonies would get engines very much better adapted to their wants. I do not mean to insinuate that consulting engineers do not know their business, but I think that locomotive builders are likely to know at least as much, considering the years of experience they have had solely devoted to this one particular class of engineering. Moreover, were they allowed a freer hand, so as to be able to utilise as far as possible their existing patterns and drawings, engines might be turned out of equally good design at a much lower cost and in much less time. So far as I have been able to find out, when a Colonial road buys American engines it buys the American builders' standard; whereas, as I have already pointed out, when it buys English-built engines it employs a consulting engineer, who issues elaborate specifications and drawings which must not be modified in any way.

There would be no difficulty in giving endless examples of the above, but I will content myself with one which occurred in my own works a short while back. I had in hand, at the same time, three different orders for locomotives, all the same type, size and gauge, but the cylinders were of the following sizes:—14in. by 18in., 14in. by 19in., 14in. by 20in. There was also a few inches difference in the wheel base, and a fraction of a square foot difference in the area of the fire grate. No deviations were permitted from any of the three specifications, which therefore necessitated preparing three complete sets of patterns, drawings, gauges, templates, &c., where one ought to have sufficed. You must therefore admit that the two opposing builders are not comparable one with another, and it is scarcely fair on your part to saddle the English contractor with faults of design with which probably he had little or nothing to do. I enclose my card, but for obvious reasons prefer to sign myself Kay-Fist.

October 4th.

### ALUMINIUM TORPEDO BOAT.

Sir,—The accounts of this speedy little vessel have been most interesting. It will be noticed that an additional speed of 3½ knots is claimed from the use of the new metal, and it is further stated that the speed of a similar boat in steel would be 17 knots only. But in your issue of December 11th, 1891, an account appears of an apparently precisely similar craft, namely, 60ft. long by 9ft. beam, and having a water-tube boiler, with triple expansion engines developing 300 indicated horse-power, also built by Messrs. Yarrow and Co., the mean speed of which, taken from six runs, is there said to have been 20·03 knots—the highest single run being given as 20 57; the difference in speed, therefore, between this craft and the new one of aluminium appears to be 0 528 only, or roughly speaking, ½ knot, and not 3½ knots.

Admitting that the figures 20 558 are obtained from two hours' continuous steaming, and 20·03 from the mean of six mile runs only, calculations based on the trials of a number of fast torpedo boats and "Destroyers" give us the difference between the average of the mile runs, and three hours' continuous steaming, and this difference reduced to 20·558 knots gives an increase of ·36 of a knot as the highest average mile speed above the longer time trial. It is, therefore, to be presumed that the new boat could have developed at the most an additional ⅓ knot if mile runs had been adopted. So that, assuming the most favourable possible terms, the total gain in speed works out at slightly over ⅞ of a knot, instead of 3½ knots.

Whatever, then, the advantages of aluminium may be, and doubtless it has some—when its price ceases to be practically prohibitive—a great increase in speed does not appear to be amongst them, assuming the above data to be correct, and a 40-knot aluminium Havock, as suggested in this week's daily press, is at present, at all events, quite chimerical.

It would be interesting to know what is the highest speed Messrs. Yarrow consider this little boat could develope, in light trim, and on a mile. Perplexed.

October 8th.

---

Sir,—As some of the statements that have been published in connection with the above subject are not quite accurate, and may, therefore, be misleading, I shall esteem it a favour if you will kindly give publication to this letter in your next issue.

The price of 3s. to 5s. per lb. does not represent the price of the metal itself, but that of angle irons, bars, castings, &c, of the suitable aluminium alloy used, which is quite a different matter. Aluminium in ingots is now sold in the market at 1s. 9d. per lb., and taking into consideration that the weight of this metal is one-third of that of the other metals commonly used in shipbuilding, this price really represents only 7d. per lb. if compared with them.

It is quite true that the prime cost of this torpedo boat, or of any other ship made of aluminium, will be somewhat greater than that of the same sized ship built of steel, but the former with engines of the same horse-power will attain much greater speed. With regard to the boat in question, a speed of 20½ knots was obtained in place of 17 knots, this being the rate of the ordinary steel boats. It is therefore evident that an aluminium boat, for the same rate of speed, will require less horse-power, which means considerable economy in the consumption of fuel, and this in a short time would fully compensate for the extra first cost. This is quite irrespective of the other advantages of aluminium for shipbuilding purposes, which are fully explained in your interesting article.

It has been stated that we are not equal to other countries in the production of aluminium, and that this is due to natural causes. It is quite true that none of this metal is now made in the United Kingdom, but there is absolutely no natural cause why it should not be produced here as cheaply as in other countries. In fact, the British Aluminium Company has been formed for this purpose, and is now completing arrangements for starting a large factory for the production of aluminium in this country by electricity. The raw material is to be found in Ireland in large quantities, and of good quality; water power for generating electricity can be obtained quite as cheaply and conveniently as abroad; and by using the same patented processes for the production of aluminium by electricity which have been so successfully used in France, Switzerland, and the United States of America, this company will be able to produce the metal as cheaply in this country as elsewhere.

For The British Aluminium Company, Limited.
(Charles F. Jones, Secretary.)

### ELECTROLYTIC SANITATION.

Sir,—In your issue of September 28th we notice an article headed "Electrolytic Sanitation," in which you comment on the Hermite process of disinfection. We must request you to allow us a little of your valuable space for a few remarks upon this article. The commencement of the article promised an impartial review of the subject, and we regret that this was not adhered to in your subsequent remarks. We fear to take up too much space in mentioning all the points which might be brought forward, and will therefore point out only one or two of the most striking statements with which we do not agree.

The article says, "Seawater is a wasteful material to choose in the preparation of a bleaching and sterilising liquid," &c. We venture to suggest that it is not proved that the organic matter in the salt water is the cause of the reduction in strength of the electrolysed salt water when diluted. It is sufficient to our mind that seawater can be run up from no chlorine strength to ·7 grammes of chlorine per litre, with an average yield of 1 gramme per ampère hour, which, as you will see, is fairly good approximation of a theoretical yield.

We think the reference to "magical compounds" and "wand of the patentee" is not consistent either with proper treatment of this subject or of the absolutely public way in which everything connected with this process has been carried on. Mr. Hermite or ourselves have never made any claim for any magical compound, nor in fact have ever encouraged any mystery. Our simple statement is that we can produce a disinfecting liquid of sufficient strength to sterilise sewage absolutely by electrolysing sea water with a yield of one gramme of chlorine per ampère per hour, and that in our apparatus the necessary electro-motive force does not exceed 6 volts. Therefore with 1000 ampères × 6 volts, we produce 1000 grammes of chlorine per hour.

Anyone caring to work out the cost can do so from this data. The suggestion that a solution of bleaching powder could be distributed in the way that we propose to distribute our disinfectant is rather startling, and we do not think would be seriously considered by any engineer. We think it unnecessary to do more than point out that practically one-third of bleaching powder is all that is useful, the remaining two-thirds, consisting of lime, would have to be got rid of. Anyone familiar with the working of paper mills and bleach works will appreciate the difficulty of getting rid of the refuse. Imagine a large town supplied in this way, and using many tons of bleaching powder per day, two-thirds of which they would have to dispose of otherwise than in the sewers. No suggestion is made as to how this difficulty is to be overcome, nor indeed is any practicable method proposed as to either mixing and using this powder, nor of carrying on the proposed dioxydising process.

There is no possible comparison between the Hermite process and such a suggestion, because the one is workable and the other is not. What can be simpler than sea water flowing continuously through an electrolyser and into the sewers? Again, those connected with the chemical trade might ask, where would bleaching powder be found if such a demand were to arise?

Paterson and Cooper.

### CONDITION OF THE THAMES.

Sir,—I am pleased to see that you have brought to the notice of your readers the condition of the river Thames at low water near Kew Bridge, which bridge will no doubt be removed shortly. The new bridge having fewer buttresses, will enable the water to flow out quicker than now.

In the year 1885 I was one of the competitors for the disposal of the London sewage; my scheme removed the sewage out of the way from London, and improved the Thames from Teddington to Coal House Point. Your illustration called to my memory a paragraph in my scheme. It runs as follows:—Residential property adjoining the Thames at Teddington, Twickenham, Richmond, Isleworth, Kew, Mortlake, and Putney are not healthy, owing to the river being nearly dry several hours each day in the summer time, the tide being much more swifter than of old. The first impediment to the tide flowing out was the removal of old London Bridge. At this old structure there was a fall of 5ft. from the upper side to the lower side, five arches being blocked up for the London Bridge Waterworks. The river on the upper side of the bridge presented the appearance of a lake—*vide* old prints. The next impediment to the flowing out of the Thames was the removal of old Westminster Bridge with its numerous arches. The next was the shoals at Waterloo Bridge. I have walked nearly across the river near the bridge many times when a boy. The paragraph goes on to say, now for the final, you have only to remove Old Battersea, Putney, and Kew Bridges, and the flats or shoals at Hammersmith, and you have done it. There will not be much water left in the river at the places indicated for several hours per day. This was written over nine years ago, and now it is a reality. If you lock the river at Putney, you will still have trouble lower down. HENRY SPORTON.

Middlesex, October 9th.

### MIDLAND RAILWAY CARRIAGE STEPS AND FITTINGS.

SIR,—The Midland Railway Company is now running, on its express trains between Edinburgh and London, some carriages which would be a disgrace to even a small railway company. The steps are a positive source of danger to the public, being of thin iron barely the width of the carriage doors, so that should anyone slip between the carriage and the platform their legs must inevitably be cut off by these knife-like appendages. These small iron steps are slippery, and a continuous wooden footboard should be insisted on by the Board of Trade. The standard door handle adopted by the Midland Company is also about the worst that could possibly be designed, and appears to have been handed down from the old coaching days; it requires two forces to be expended in its use, one to lift up and keep steady the movable ring and another to turn it. This form of handle must cost more to make, and is not nearly so convenient as the cross handle in general use by other companies. It is strange that the Midland Company should have gone out of their way to adopt as their standard handle one so hideous in design and so inconvenient in use, and one which, moreover, is not even automatic in its action, and therefore dangerous, more especially when most other companies, even small ones, have adopted door locks which are both convenient and automatic in their action, so that when pushed to they automatically lock themselves.

Of the different kinds in use, Wethered's patent is perhaps the simplest and best. It is used on the Metropolitan Railway and also the new West Highland Railway, and I would suggest to the Midland Company that they adopt either this or some other automatic door lock as their standard pattern. One would not expect so influential and go-ahead a company as the Midland to be so far behind the times in the matter of carriage fittings.

Constitutional Club, London, PERCY CALDECOTT.
October 8th.

### THE THEORY OF THE STEAM ENGINE.

SIR,—Mr. Maurice Cross's letter in your last issue appears more explicit than his previous communications. In reply, first, as I have already stated, Rankine refers to experiments made by Mr. C. W. Siemens as the basis of his statement that steam freely expanded becomes superheated. Secondly, Mr. Cross seems to object to wire-drawing being employed in investigating the results of free expansion. At the same time he lauds Joule and Thompson's experiments on free expansion. This is highly inconsistent, since Joule and Thompson arrived at their conclusions by wire-drawing apparatus. Thirdly, he appears to regard steam, *i.e.*, the gaseous form of water, as not a "permanent" gas, whereas it is quite as much a "permanent" gas as air or carbonic anhydride or other such gaseous body.

I have my own opinions as to the manner in which the "efficiency" of a steam or other heat engine is most justly to be calculated. This part of the correspondence or controversy I have no wish to deal with, and will refrain from saying further than that I totally disagree with Mr. Cross's views in so far as I understand them. HENRY CHERRY.

21, Festing-road, Putney, S.W.,
October 10th.

## AMERICAN ENGINEERING NEWS.

*(From our own Correspondent.)*

*New passenger station.*—A handsome station is now being built by the New York Central Railroad at Syracuse, to replace the old station. As this is a through station the main building will be at the side of the tracks. This building will be 122ft. by 94ft. in plan, three storeys high, with a steep pitched roof, and the tower will be 20ft. square and 80ft. high, surmounted by a pyramidal roof. The exterior will be of dark red sandstone, quarry faced, with dressed stone facing, and the roof will be of Spanish tile. The main waiting-room will be 90ft. square; women's waiting-room and men's smoking-room 24ft. square, each with a toilet-room 12ft. by 14ft.; parcel-room, 15ft. by 20ft.; ticket office, 18ft. by 24ft., with one end partitioned off for ticket offices for the sleeping car companies; baggage-room, 57ft. by 50ft.; trainmaster's office, 14ft. by 18ft.; and a restaurant, 128ft. by 28ft. in the basement. From the main hall a subway passes under the tracks, with steps to the main platforms. The upper floors of the building will be occupied by railway offices. The building will be heated by fifty steam radiators, and lighted by 500 incandescent lamps, the light, heat, and power plant being located in a separate building. The train shed will cover seven tracks, four of which are through main tracks, and the three main platforms will be 25ft. to 36ft. wide, 1ft. above the rails. There will be ticket inspectors' offices at each end of the platform at the head of the stairways from the subway. The train shed will be 480ft. long and 128ft. wide, with main roof trusses 110ft. long, and a cantilever roof on the outer side opposite the station building. The interior decoration and fittings will be very complete and elaborate.

*Railway statistics (Chicago, Milwaukee, and St. Paul Railway).*—In former letters I have given details of the operating statistics of some of the important railways, and below are given similar details respecting the results of operation of the Chicago, Milwaukee, and St. Paul Railway—a system comprising 6147 miles—during the year ending June 30th, 1894. The dividends for that year aggregated 7 per cent. on the preference stock, and 4 per cent. on the common stock. The freight and passenger traffic and the total earnings were less than for 1893, but the freight and passenger revenue increased:—

| | |
|---|---|
| Gross earnings, dols. | 31,327,951 |
| Total operating expenses, dols. | 20,114,333 |
| Net earnings, dols. | 11,213,618 |
| Miles operated | 6,147 |
| Miles run by passenger trains | 7.848 438 |
| " " freight trains | 12,869,482 |
| " " mixed trains | 987,704 |
| " " revenue trains | 21,705,624 |
| " " switching trains | 4,411,146 |
| " " construction trains | 575,700 |
| Total train mileage | 26,692,470 |
| Passengers carried | 7,921,882 |
| Passengers carried one mile | 337,133,338 |
| Average journey per passenger, miles | 42 56 |
| Revenue per passenger per mile, cents | 2 169 |
| Revenue per passenger per train mile, cents | 90 320 |
| Tons of freight carried | 10,794,058 |
| Tons carried one mile | 2,077,869,479 |
| Tons per loaded car | 9 93 |
| Average haul per ton, miles | 192 50 |
| Revenue per ton per mile, cents | 1·037 |
| Revenue from freight per train mile, dols. | 1·5834 |
| Expenses per revenue train mile:— | |
| For repairs of engines, cents | 5·05 |
| For repairs of cars, cents | 7 05 |
| For station service, cents | 12·82 |
| For train service, cents | 7·34 |
| For locomotive service, cents | 8 87 |
| For train and station supplies, cents | 2·44 |
| For fuel, cents | 10·49 |
| For oil and waste, cents | 0·63 |
| For all other expenses, cents | 37 98 |
| Total operating expenses, cents | 92·67 |
| Percentage of operating expenses to earnings | 64 21 per cent. |

*Railway statistics (Wabash Railroad).*—The following detailed operating statistics are from the report for the year ending June 30th, 1894:—

| | |
|---|---|
| Miles per day per freight train | 85 |
| Freight train miles per day | 17,170 |
| No. of passenger trains per year | 46,092 |
| Miles per day per passenger train | 112 |
| Passenger train miles run per day | 14,112 |
| Cost of locomotives per 100 miles run:— | |
| Repairs (dols.) | 3·34 |
| Stores (dols.) | 0·29 |
| Fuel (dols.) | 4·75 |
| Enginemen and firemen (dols.) | 6·06 |
| Wiping and dispatching (dols.) | 0·89 |
| Total cost per 100 miles run (dols.) | 15·33 |
| Average mileage per engine per year | 43,116 |
| Average mileage per month per engine | 3,593 |
| Cost per ton of coal on tender (dols.) | 1·13 |
| Miles per ton of coal | 23·80 |
| Average number of loaded cars per freight train | 14·69 |
| Average number of cars per freight train | 21·57 |
| Average load per freight train (tons) | 175·39 |
| Average earnings per freight car (cents) | 8·33 |
| Average expenses per freight car (cents) | 7·24 |
| Average number of cars per passenger train | 4·79 |
| Average number of passengers per train | 40·96 |
| Expenses per passenger car per mile (cents) | 19·34 |
| Earnings per passenger car per mile (cents) | 12·91 |
| Miles operated | 1936 |
| Earnings per mile (dols.) | 6485 |
| Operating expenses per mile (dols.) | 5079 |
| Net earnings per mile (dols.) | 1406 |
| Tons of freight carried | 5,414,994 |
| Tons carried one mile | 1,097,585,279 |
| Rate per ton per mile (cents) | 0·698 |
| Expenses per ton per mile (cents) | 0·607 |
| Net earnings per ton per mile (cents) | 0·091 |
| Freight train mileage | 6,258,093 |
| Freight train earnings per mile (cents) | 122·35 |
| Freight train expenses per mile (cents) | 106·40 |
| Freight train net earnings per mile (cents) | 15·95 |
| Average load per car (tons) | 11·94 |
| Average freight train load (tons) | 175 39 |
| Number of passengers carried | 3,724,674 |
| Number of passengers carried one mile | 210,281,487 |
| Rate per passenger per mile (cents) | 1·877 |
| Expenses per passenger per mile (cents) | 1·508 |
| Net earnings per passenger per mile (cents) | 0·369 |
| Passenger train mileage | 5,133,272 |
| Passenger train earnings per mile (cents) | 92·61 |
| Passenger train expenses per mile (cents) | 61·79 |
| Passenger train net earnings per mile (cents) | 30·82 |
| Number of paying passengers per car | 11·49 |
| Number of paying passengers per train | 40·96 |

*Electricity for handling heavy guns.*—Successful experiments as to the use of electricity for moving heavy guns and revolving turrets on warships have been carried out by the Ordnance Bureau. Tests have been made on the double-turret monitor Montauk in turning the turrets and training the 10in. guns. A device has been perfected by Captain Sampson, of the Bureau, by means of which one movement of a lever enables the rotary motion of the turret and the vertical motion of the gun to be done at the same time, thus facilitating the work of training the gun, and the rapidity of action is quicker than where steam power is used. In the experiments on the Montauk, the old-fashioned turrets were moved easily and rapidly, and the guns were lowered or raised and turned in the direction of the target at the expense of little energy and without appreciable loss of time. The movements were more rapid than when steam is employed, and the accuracy was greater. The advantages noted for the proposed new system were many. Chief among them were the ease and economy of the plan. Wires can readily be attached to the dynamos of the main electric plant, and the power be thus transmitted to turrets and guns. Should a wire be shot away, it can be quickly spliced or a new one laid, and the firing go on without long interruption. There are no valves and other delicate gearing to get out of order and destroy the efficiency of the battery at a critical time. The present plan is to install the new system on the Iowa and Brooklyn. It is not intended to remove the steam motors on the vessels now in commission, or which have advanced in construction to such a stage as to make the change an expensive one.

*Automatic block signals.*—Automatic block signals showing "danger" as the normal position, which is a new feature in automatic signals, are now in operation on about eighty miles of double track road. The signals are on the Hall system, with a circular box or case having an 18in. circular opening, behind which appears a red disc for the "danger" signal. Over this large opening is a smaller one for the night signal. The electrical appliances are enclosed in the case, which is mounted on a post or upon an overbridge. A track circuit is used, and switches are interlocked with the block signals. The blocks are from a quarter of a mile to one mile long. There are no distant signals, but a train passing one signal sets it at "danger," but the signal behind does not show "safety" until the train has gone 1500ft. further.

*Swaging machines.*—Machines for cold swaging metal articles are being quite extensively used in the production of small pieces of which large quantities are required, the work being done by pressure between revolving dies, the outer ends of which touch intermittently the faces of a floating ring of rollers in a circular frame concentric with the dies. The stock does not revolve, but the dies revolve around the stock. One of its most extensive uses is in the manufacture of sewing-machine needles, which are swaged down to shape from blanks the diameter of the shank of the needle, the machine requiring only to be supplied with blanks. Tubes can be swaged without the use of any mandril. Amongst the smallest and most delicate work done are tubes for hypodermic syringes, which are of steel with a hole through them 0 015in. diameter when finished. Another example of small work is in making "rolled plate" wire for manufacturing jewellers. A cylindrical piece of base metal about 1½in. diameter is covered by a case of gold, which is drawn in a drawing press from a flat blank the same as cartridge shells are drawn. The gold case is soldered to the core, and the whole is then reduced by these swaging machines to such diameters as are suitable for eye-glass chains, &c., some of it being swaged down to 0·015in. diameter. The applicability of the process to tubing for bicycle frames, &c., is shown by the fact that steel tubing $\frac{3}{32}$in. thick, 1in. diameter, is reduced to $\frac{7}{8}$in. diameter, and when the straight reduced portion of the tube is 6in. to 10in. long, about five pieces per minute can be done. Tubes for bicycle frames are sometimes reinforced at certain points requiring extra strength, and this is done by simply inserting a short piece of smaller tubing at the desired point and swaging the outer tube down upon it. In the manufacture of bicycle spokes, the wire is taken from a coil, straightened, passed through the hollow spindle of a swaging machine and reduced to a proper diameter by swaging, but leaving unswaged sections at proper intervals, which, when sheared in two at the middle, leaves the spokes large at each end for heading, bending, and threading. All this is done continuously and automatically. Three tensile tests of swaged and unswaged wire—0·072in. and 0·092in., 0 083in. and 0·115in., 0·08in. and 0·105in. diameter—from the same coils, showed an increase for the former of 9, 14, and 15½ per cent. respectively, the two first being for crucible steel wire and the third for Bessemer steel wire.

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Engineers: W. R. Lawton, to the Hebe, and Reginald W. Parry, to the Pembroke.

THE HERMITE ELECTRICAL SANITATION PROCESS.—The Ipswich Town Council decided at their meeting on Wednesday, the 10th inst., to adopt the Hermite process. This decision was unanimous, and resulted from the exceedingly favourable report submitted by the sewerage committee on the trials which have been made on the main sewers of the town during the last three months. We understand the permanent installation is to be proceeded with as rapidly as possible. We hope in our next issue to give further details.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

*(From our own Correspondent.)*

THE quarterly meetings of the iron trade have been held this week in Wolverhampton on Wednesday and in Birmingham to-day—Thursday. Taken altogether they have been fairly prolific of business, though many sellers would have liked to do more. A healthy demand was present for iron and steel of most descriptions, and improved prices were here and there secured. A good sign of the times is the accentuated demand for bar iron, and it is gratifying to hear makers declare that they have lately obtained larger orders. Marked bars were re-declared on the basis of £7 10s. for ordinary branded qualities, and £8 2s. 6d. for the L.W.R.O. production of the Round Oak Iron and Steel Company. Merchant bars were £6 10s., and common bars £5 10s. to £5 15s. The official prices of marked iron have not remained unaltered since January, 1893. Common bars as compared with a year ago are cheaper to the extent of 5s. to 7s. 6d. per ton, but this is explained by the circumstance that the coal strike of last autumn was the means of advancing prices of all iron. A more justified comparison is that with three months back, when common bars were quoted £5 10s.

An animated trade is being done in sheets, and it is not unlikely that before long prices will further rise. Galvanised corrugated qualities of 24 w.g. were to-day £9 15s. to £9 17s. 6d., but several makers would not entertain business at less than £10 for delivery Liverpool f.o.b., or £10 2s. 6d. delivery London. Galvanising sheets were strong at £6 12s. 6d. to £6 15s., doubles, and £7 5s. to £7 10s. trebles.

Sellers quoted cold rolled and close annealed sheets for japanners, £8 to £8 5s. doubles, and £8 15s. to £9 lattens, while the same sheets in steel were £8 5s. doubles, and £9 to £9 5s. lattens. Iron hoops were rather active at £6 10s., though makers stated that as yet no large orders had been received from the United States, as a result of the passing of the American Tariff Bill. Gas strip was rather slow at £5 15s., thin strip £6 10s., and locomotive boiler strip, either in iron or steel, £5 15s. A large demand was recorded for steel strip for bedstead tubes.

Pig iron sellers recorded a steady business, and in many instances contracts were concluded for delivery to the end of the year. Native all-mine hot-blast pigs were 55s. to 60s. per ton, medium qualities 42s., and common cinder 38s. upwards. Outside irons were in prominent request, and agents quoted the following prices: Derbyshires, 42s. 6d. to 43s.; Northamptons, 41s. 6d. to 42s., and Lincolns, 43s., the two former being delivered here less 2½ per cent. and the latter net. North Staffordshire grey forge of good make was 43s. 6d. delivered here, while foundry qualities were 50s. for No. 1; 47s., No. 2, and 46s. No. 3.

Official statistics issued this week show that the number of blast furnaces now blowing in the Midland and Staffordshire district is as follows:—Derbyshire, 26 out of 52 built; South Staffordshire, 22 out of 76 built; North Staffordshire, 13 out of 38; Leicestershire, 3 out of 4 built; Northampton, 12 out of 28; Lincolnshire, 14 out of 21; Nottingham, 3 out of 4; and Shropshire, 4 out of 10. These returns do not evidence much change on three months ago, but taking the entire furnaces of the United Kingdom, the returns are a decline of no fewer than 52 furnaces on three months back, the result mainly of the Scotch strike.

A spirited inquiry was noted for steel, and it is significant from the increasing number of orders that a larger consumption is at present taking place of this material than perhaps at any previous date. Bessemer blooms and billets were quoted this week £4 4s. net; Siemens qualities, £4 6s. 6d.; soft steel plates, suitable for bridge and other engineering purposes, £6; and boiler plates, £7. Steel bars, flats, strips, &c., used for stamping and pressing purposes, and rolled down in this district, were generally 10s. per ton above the price of iron.

The steps which mining engineers will have to adopt to maintain the prosperity of the collieries under a system of eight hours for miners were suggested by Mr. Alexander Smith, the new president of the South Staffordshire Institute of Engineers, in his inaugural address on Monday. More coal would have to be turned out for the same capital outlay, so as to spread the interest on fixed capital and standing charges over a larger tonnage. This could be done in one or two ways, such as working two shifts and improvements in machinery and other arrangements. Prominent among the possible improvements were the introduction of mechanical coal-cutting, more rapid haulage and drawing, and the provision of coal-washing and coal-picking apparatus, for making the best market possible of the coal raised. Whenever the eight hours system came into force greater pressure and responsibility would be thrown upon mining engineers, and prompt thought should be exercised by the profession as to how these new conditions were to be met.

The wages dispute in the wrought nail trade is likely to be settled by the masters paying the 1890 list, for which the men have been agitating. At least, the operatives believe that at the adjourned joint conference which is to be held the employers will be willing to concede these terms, and upon this understanding it has this week been resolved to resume work at once.

A company with a nominal capital of £75,000 has just been formed locally to take over the business of the Eagle Range and Foundry Company, Aston, near Birmingham, cooking range and heating apparatus engineers. The object of the new limited concern is to develope the present business, and it is said that the average profit for the last five years has been considerably in advance of any previous period.

The goodwill, registered trade marks, brands, &c., of the New British Iron Company, in liquidation, have been purchased by the well-known firm of Messrs. N. Hingley and Sons, Netherton Iron Works, near Dudley. Messrs. Hingleys' mines adjoin those of the North British Iron Company, and are situated in the same beds of coal and ironstone. It is their intention to continue the manufacture of "Lion" iron exactly as heretofore produced under that celebrated mark. "Lion" pig iron will also be made at Corngreaves' furnaces, and used in making bar and plate iron of the "Lion" brand.

The rating of machinery assessment appeals by the Wolverhampton manufacturers, and which were to have come before Quarter Sessions, have mostly been settled out of Court. Originally fifteen appeals were down for hearing, but only one of these, and that not relating to a manufacturing business, has actually come for trial. In the other cases arrangements agreeable to the appellants have been consented to by the Union authorities. It is stated that the actual result of the re-assessment of the borough will be a very large increase in the rateable value, and that although reductions have in numerous instances been allowed on the original re-assessments, the net results will be most satisfactory from a ratepayer's point of view.

## NOTES FROM LANCASHIRE.

*(From our own Correspondents.)*

*Manchester.*—The tone throughout the engineering and iron industries of this district continues one rather of depression than otherwise, and a very emphatic proof of the generally unsatisfactory condition of trade is the fact that notwithstanding the excessively restricted production of pig iron, as shown by the recent returns of the number of furnaces in blast and the almost complete absence of stocks of any weight, business seems to be impracticable on anything like a remunerative basis. If there were any confidence whatever with regard to a revival of trade, the present position of stocks and the large number of furnaces out of blast could not help but give a stimulus to some substantial advance; but there seems to be no confidence in buying, and business is again dragging on in the merest hand-to-mouth fashion, with prices tending in a downward direction. So far as the engineering industries are concerned, there is still no indication of any real improvement; here and there, of course, business fluctuates, and in isolated cases more activity is reported, but generally establishments continue but very indifferently employed, and new work generally is not coming forward in any increasing weight.

The Manchester Iron Exchange on Tuesday was but thinly attended, and only a very slow business was reported either in raw or manufactured material. For pig iron only the most restricted inquiry is coming upon the market, and merchants and consumers are in many cases only taking partial deliveries of the iron that was purchased during the rush of buying a few weeks back, with the result that makers, although well sold, are here and there having iron thrown on their hands, which they are showing rather more anxiety to sell, even where they have to take something under recent quoted rates. For Lancashire pig iron quotations remain nominally on the basis of 40s. for forge to 42s. foundry, less 2½ at the works, but at these figures there is practically little or nothing doing of any moment in local brands. For district brands prices are easier if anything, one or two of the Lincolnshire makers especially showing more disposition to entertain offers, and forge qualities could be bought readily at 39s., with foundry numbers scarcely averaging more than 40s. 6d., and quotations for foundry Derbyshire remaining nominally at 45s. up to 46s. net cash, delivered Manchester. With regard to outside brands offering here, the continued scarcity of Scotch iron keeps up fully late prices, Eglinton not being quoted under 49s. to 49s. 6d., and Glengarnock 51s. net prompt cash, delivered at the Lancashire ports; but Middlesbrough could be bought at lower figures, makers who still hold to 45s. 4d. net cash for good-named foundry brands, delivered equal to Manchester, finding these prices practically out of the market, as there are ready sellers at quite 6d. under this figure.

In finished iron new business still comes forward very indifferently, and it is exceptional where manufacturers are able to keep their forges running more than four days per week. Quoted prices remain unchanged, but the tendency is towards less firmness. Delivered Manchester or Liverpool, Lancashire and North Staffordshire bars remain at £5 7s. 6d. to £5 10s.; Lancashire and Staffordshire sheets, £7 to £7 5s.; and Lancashire hoops, £5 17s. 6d. for random, to £6 2s. 6d. for special cut lengths. Nut and bolt makers report only a slow demand, the large users, such as bridge builders and boiler makers, being only quiet, and very low prices have to be taken to secure orders. With regard to bridge work, I may, however, mention that contracts have recently been secured by local firms, but these, I understand, have been taken at excessively low figures.

The steel trade continues very quiet, with ordinary foundry hematites not averaging more than 53s., less 2½; ordinary Bessemer basic billets, £4 net cash; and steel boiler plates £6 5s. per ton, delivered in this district.

In the metal market there is no change in quoted list rates for manufactured goods, but buying goes on very slowly from hand to mouth.

The Ashbury Railway Carriage Company, Manchester, have just secured orders for twenty-four complete bogie carriages of various classes for the Ceylon Government Railways, and they are just now busily employed upon another important order for ninety-two underframes, together with the ironwork and fittings, for various classes of carriages, for the Indian State Railways.

The Vaughan Pulley Company, of West Gorton, have just completed extensive additions to their works, and have laid down special machine tools for the manufacture of their wrought iron pulleys with steel rims, which will about treble their capacity for turning out their special class of work. I may add that the firm are very busy with orders, both on home account and for shipment to all quarters of the globe, the exceptional lightness, which is one of the special features of the Vaughan pulleys, rendering them particularly adaptable for export.

The fifty-sixth annual meeting of the Manchester Geological Society was held on Tuesday, Mr. W. Saint, Inspector of Mines, the president, occupying the chair. The report presented showed a continued increase of membership, and improvement as regards the financial position of the Society, the total membership being now 230, as against 222 last year. The report, in reviewing the work of the session, made reference to several important contributions on mining and geological subjects. The President had opened the session with a very practical address on "Recent Improvements in Mining Machinery and Appliances," this being followed by papers on ventilating and coal-cutting machinery, in which the desirability was set forth of a more extended adoption of mechanical appliances for the getting of coal, which so far had made very little progress in this country. On geological subjects, Professor Boyd Dawkins had contributed an important paper on the "South-Eastern Coalfield at Dover," and Mr. De Rance had given an interesting paper, with detailed sections, of a boring for coal on the Freeholders' Estate, at Hazel Grove, which had resulted in the finding of valuable seams of coal and proved the extension of the coalfield beyond the boundary previously assumed. A matter of some importance which had engaged the attention of the Council during the session had been the desirability or otherwise of the association joining the Federated Institution of Mining Engineers, but with regard to this, nothing had so far been definitely settled. Mr. W. Watts was elected President, and Messrs. G. Pearce, John Gerrard, H. Speakman, Mark Stirrup, vice-presidents; Messrs. R. Clay, S. Garside, George Wild, W. N. Atkinson, C. Cockson, R. Winstanley, S. Platt, J. Ridyard, H. H. Bolton, G. B. Harrison, D. H. F. Matthews, and G. C. Greenwell, junior members of Council; Mr. Clegg Livesey, hon. treasurer; Messrs. J. Tonge and Joseph Crankshaw, hon. secretaries; and Messrs. G. H. Hollingworth and H. A. Woodward, hon. auditors for the ensuing year.

No really material improvement can be reported in the position generally as regards the coal trade. In the better qualities of round coals, suitable for house-fire requirements, an increasing business is being put through, and pits have in isolated cases been able to run about full time, but in other descriptions of fuel, only a very indifferent demand is reported to be coming forward, and four days per week continues the general average that the pits are working, with supplies ample for requirements, even with this limited production. With regard to house coals, prices average about 11s. to 11s. 6d. for best qualities, 10s. to 10s. 6d. for seconds, and 8s. to 8s. 6d. for common house fire coals at the pit mouth, but the top figures still represent exceptional prices, although they are more readily obtainable, in some instances, than they have been recently. Only a very slow inquiry is coming forward for steam and forge coals, which are readily obtainable at 7s., although 7s. 6d. is quoted for some of the better qualities at the pit mouth.

Engine fuel continues more or less of a drug in the market, and in some cases extremely low prices are taken to effect clearance sales; common slack averages about 3s. 6d. to 4s., good medium sorts 4s. 6d. to 5s., and best qualities 5s. 6d. to 6s. per ton at the pit mouth.

During the past week there has been a falling-off in the weight of business put through for shipment, this being chiefly due to the cessation of inquiries for Scotland, and there is a slight giving way in prices, which do not average more than 8s. 6d. to 9s. per ton for ordinary qualities of common round coal, delivered at the Mersey ports.

*Barrow.*—There is still less activity to report in the hematite pig iron trade this week, and a distinct tone of depression has set in. Orders are very few, especially for forward deliveries, and prompt sales are from hand to mouth. There has been a further decrease in stocks this week amounting to 417 tons, and stocks now stand at 158,490 tons, or 63,867 tons more than in the beginning of the year. Prices are depressed at 44s. 6d. to 45s. for mixed Bessemer Nos., net f.o.b., with warrant iron at 43s. 6½d. cash sellers, buyers at 43s. 6d. Thirty-three furnaces are still in blast.

Iron ore is in slow demand, but Scotch smelters are again wanting deliveries, and some improvement in shipments may be expected. There is a quiet local demand. Late prices are maintained.

The steel trade is still very quiet, except in three departments. Some new orders are to hand for steel ship plates, and for heavy steel castings, and it is expected there will be a fair trade during the winter months in tin-plate bars, but rails, heavy as well as light, are in quiet demand, and there is but little doing in billets and hoops, while the trade is almost absolutely nil in blooms, slabs, and wire rods. The Bessemer departments generally are inactive.

The shipbuilding and engineering trades are fairly well employed, and much progress is being made with the Admiralty work in hand. The Naval Construction and Armaments Company have booked an order from the London and North-Western and the Lancashire and Yorkshire Railway companies for the building of a high-speed twin-screw passenger steamer for the Fleetwood and Belfast service. Recent additions to this fleet have been made by Laird's, of Birkenhead, and by Denny, of Dumbarton. In years gone by the Barrow Company built three vessels for the Fleetwood service, but they were of the now discarded paddle type. Greater economy in working is secured by the twin-screw steamers, and higher speeds are obtained.

Shipping returns show an improvement this week. The exports of pig iron from West Coast ports during the week amount to 6793 tons, and of steel 6599 tons, compared with 4080 tons of pig iron and 4781 tons of steel in the corresponding week of last year, an increase of 2713 tons of pig iron and of 1818 tons of steel. The aggregate shipments this year amount to 277,654 tons of pig iron and 313,183 tons of steel, compared with 208,663 and 383,950 tons respectively in the corresponding period of last year, an increase of 68,991 tons of pig iron and a decrease of 70,767 tons of steel.

The demand for coal and coke is quiet, and prices are, generally speaking, easy.

Throughout the district generally there is scarcity of employment, and many men coming into the district for work have to go elsewhere disappointed.

It is reported that a new company is about to be formed to produce, at a Barrow works, a new material to take the place of silk.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THIS has been a very dull week in the steel and iron trades. There has been practically no movement reported. In all the works visited during the last ten days the reply to inquiries has been one continuous note of depression. No signs whatever are perceptible of any improvement in the demand either for railway material or for shipbuilding. Shipowners are discouraged at the lowness of freights, which makes their business altogether unprofitable. As long as ship-carriage is thus so unsatisfactory it would be unreasonable to expect any new orders of consequence to be placed. Hematites run from 51s. to 52s. 6d. per ton, delivered in Sheffield; common forge iron, 38s. to 38s. 6d. per ton, but there is literally no business doing. Consumers have quite sufficient supplies for their requirements, and the absence of new work causes them to hold their hands and keep back orders. The position of affairs is exceedingly unsatisfactory and disappointing, as a decided change for the better, which was stimulated by the revival of a month ago, was expected. The quotations for hematites, already given, show a reduction of from 1s. to 1s. 6d. per ton, and in forge iron of about 6d. per ton. Derbyshire irons are also slightly reduced. Bessemer billets are at £5 10s., bar iron is quoted at a similar figure where the requirements reach any amount.

In the manufacture of locomotives and other engines, English makers, both in this and other districts, are finding German and Belgian competition get increasingly keen. Much of the work which used to be done in this country is now also turned out by native engineers in foreign markets. In several of our large railway material establishments orders are daily expected for material from India. Extensions of railways in that great Dependency are now contemplated, which will involve an outlay of over thirty millions sterling. Of this work a considerable share is certain to come to Sheffield. At the same time the prices of finished material have got to so low a point that it is doubtful whether in home industry they cover the cost. In general cases orders are said to be taken for no other object than to keep the machinery employed against better times, and to keep their men at work. The war between China and Japan has had the effect of suspending nearly all deliveries to these countries. Some pressing orders for buffers for the Japanese Government are now in course of execution in Sheffield, and when the war is over it is expected that both combatants will place heavy requirements not only in military, but in marine and railway material. The revival anticipated in the South American markets has not yet commenced, and the general opinion amongst our principal houses is that the season is too late now for the foreign markets to afford any great improvement this year.

In the coal trade 6d. to 1s. per ton advance has now been pretty generally obtained in household sorts. The long-continued mild weather led to the belief that no advance would be made this month, and merchants even yet are not buying to any extent, but owners are stubbornly requiring more money, and as the season advances they are certain to get it. Silkstone is now at 10s. to 12s. per ton; Barnsley House, 9s. to 9s. 6d. per ton; second qualities, from 8s. to 8s. 6d. per ton. In steam coal a full average tonnage is still being sent to the Humber ports, and the railway companies are taking good deliveries on account of contracts. Barnsley hards, 7s. 9d. to 8s. 3d. per ton; Parkgate and other qualities from 7s. per ton. Gas coal seems to be rather lower and in less demand. Manufacturing fuel continues very quiet, screened slack being quoted at 4s. 6d. to 5s. 6d. per ton; pit slack from 3s. 6d. per ton. Coke is in rather better demand at from 9s. to 11s. per ton.

Colliery extensions are proceeding briskly in South Yorkshire. On Monday last Mr. George H. Turner, general manager of the Midland Railway, cut the first sod of a new colliery at Griemthorpe, belonging to the Mitchell Main Colliery Company. The undertaking is on the property of Mr. F. J. Saville Foljambe, of Osberton Hall, who has granted a lease of about 3000 acres of coal, lying in such a direction that it will be connected with the workings of the Mitchell Main Colliery, Wombwell. It is expected to find the Barnsley thick seam at a depth of about 500 yards. The sinkings are to consist of two shafts, each of a clear diameter of 19ft. inside the tubbing. The coal is expected to be reached in about two years. With the two large pits already worked by the company, and the fresh enterprise in full operation, the output will be about one million tons per annum. The new colliery is connected with both the Midland and the Manchester, Sheffield, and Lincolnshire Railways. The sinking operations are in the hands of Mr. Charles Walker, of Darfield, under the supervision of Mr. Mitchell, the engineer.

On Wednesday, 10th inst., deputations of engine and boilermen from South and West Yorkshire had an interview with the executive of the South Yorkshire Coalowners' Association, the object being to require their wages to be restored to 30 per cent. above 1888 standard and to have the reductions returned. The men decline to submit to the reduction of one-fourth under the decree of the Conciliation Board, on the ground that not being represented on the Board they are not bound by its decisions. The executive are to report the result to a full meeting of coalowners to be held next week.

The return of coal sent to Hull from the Yorkshire collieries during September, issued by the Hull Chamber of Commerce and Shipping, shows that trade has been in a fairly good condition, with business as well up to what it usually is at this time of the year. The tonnage forwarded to that port last month amounted in the aggregate to 263,000 tons, as compared with 42,992 tons for the corresponding period of 1893, and 171,816 tons for September of 1892. The reason of course for the return for September, 1893, being so small was on account of the great coal strike, when practically no business was done with the Humber ports. Out of the 42,992 tons then sent, 39,552 tons came from Durham, and twenty-five Yorkshire collieries only sent 3440 tons. For the completed three-quarters of the year the tonnage forwarded to Hull was 1,591,800 tons, as compared with 1,049,480 tons for the same period of 1893, and 1,695,408 tons for the three-quarters of 1892. These figures, compared with those of 1893, exhibit an increase of half a million tons, but contrasted with those of 1892, a decrease of 103,000 tons is shown. The export trade has considerably advanced. Last month the figures were: coastwise, 19,945 tons; and to foreign countries, 147,838 tons; as against 75,607 tons in the same month of 1892. In September of 1893 no coal was exported coastwise, and only 624 tons sent away in all. The exports for the nine months of the year were:—1894, 665,462 tons; 1893, 349,807 tons; 1892, 635,089 tons. For the month of September the country which took the largest weight was Germany, with 45,458 tons. In the corresponding month of last year there was no coal sent to any foreign port except North Russia, and Sweden and Norway. Last month Sweden and Norway took 37,674 tons; North Russia, 29,680; Denmark, 12,411; and Holland, 6551 tons. For the nine months the largest weight was taken by Sweden and Norway with 215,644 tons, North Russia occupying second place with 140,158 tons, Germany being third with 117,872 tons, and Holland fourth with 37,105 tons. The highest individual tonnage sent by a single colliery was, as usual, from Denaby Main, with 23,456 tons. Peckfield, after sending moderate contributions, has sprung into second place with 16,472 tons. The third place is occupied by Manvers Main with 10,888 tons. Two collieries in West Yorkshire take fourth and sixth place, and the fifth is occupied by a South Yorkshire colliery.

During the month of September there has been the serious decrease of £20,298 in hardware and cutlery. The increasing countries for that month are Belgium, from £5937 to £8103; United States, from £12,987 to £25,314. This latter increase is due to the settlement of the tariff question. The markets which show a decrease include Russia, Sweden and Norway, Germany, Holland, France—from £8256 to £4606; Spain and Canaries, Foreign West Indies—from £3306 to £2509; Chili, from £3063 to £1291; Argentine Republic, from £3306 to £2825; British Possessions in South Africa, £12,736 to £11,577; Australasia, £24,027 to £18,868, and British Possessions in East Indies from £19,307 to £12,493. There is also a decrease reported on the exports for the nine months of £208,682. The only increasing markets are Russia—from £31,756 to £42,734; Sweden and Norway, from £28,181 to £30,477; Germany, from £82,426 to £82,905; Holland, from £56,642 to £69,336; Belgium, from £45,673 to £69,999. The decreasing countries are again very numerous, including France, from £71,008 to £55,862; Spain and Canaries, from £29,660 to £23,937; United States, £169,237 to £99,461; Foreign West Indies, from £37,706 to £28,704; Chili, from £35,134 to £14,053; Argentine Republic, from £45,866 to £35,215; British Possessions in South Africa, from £108,504 to £99,131; British Possessions in East Indies, from £167,300 to £123,842; Australasia, from £200,093 to £177,643; and British North America, from £75,295 to £52,225.

In steel unwrought there is a considerable improvement reported on the month's business. The increasing markets are Russia, from £17,660 to £39,115; Germany, from £17,834 to £30,158; France, from £6243 to £12,036; United States, from £11,704 to £32,361. Decreases are shown by the following countries:—Sweden and Norway, from £3112 to £2498; Denmark, from £3684 to £3645; Holland, from £12,815 to £7684; British East Indies, from £6394 to £3300; Australasia, from £4796 to £4593; and British North America, from £13,843 to £5995. An advance is reported on the nine months' working, the reviving markets including all except Holland, United States, and British North America.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THOUGH it is generally held that the trade of the country has entered upon a revival, and that prospects are more favourable to producers, yet in this district at present the tendency is rather the other way, and what little improvement has been gained is disappearing. Certainly the pig iron market has become very flat, and buyers are few, while plenty of sellers are coming forward, though it is but right to say that these latter are not the producers themselves, but are people who have been speculating and bought heavily when prices were advancing, in the expectation that the value of iron was going up still further. When, however, prices took a turn downward, there was the usual rush to sell out, and this prevented any recovery in prices, but rather helped them down until now they are at least 6d. per ton below the best price that has generally been realised. The unsettled state of foreign political affairs has made the speculators timid, and there is not nearly so much confidence in the market that there was a fortnight ago. Business in this district also is quieter, because less pig iron is required to be sent to Scotland, the miners' strike there having almost ended, seeing that forty thousand miners have gone back on the masters' terms out of the seventy thousand who came out more than three months ago, and coal being more plentiful the other nine of the blast furnaces have been relighted, making twelve at work altogether. There were nearly seventy in blast before the strike commenced. A good deal of capital has been made in commercial reports of the fact that between sixty and seventy furnaces could cease operations without causing any marked improvement in the demand for and prices of pig iron in other districts; but it ought to be taken into account that the consumption of pig iron fell off likewise, seeing that nearly all the finished iron and steel works in Scotland were stopped, and did not require the pig iron. If cheap and adequate supplies of fuel had been forthcoming so that they could have been kept going, a much greater improvement in the demand for and prices of pig iron in other districts would have resulted.

Cleveland pig iron makers have had to reduce their quotations, owing to the action of speculators, who have forced prices down in their anxiety to realise, and this though foundry qualities are admittedly scarce, so much so that only small lots can be furnished by the speculators themselves, and makers have little of which they can dispose for prompt delivery. Most of the business in No. 3 this week has been done at 36s. per ton for prompt f.o.b. delivery, but less than that will be accepted now—35s. 9d., and even 35s. 6d. was taken on Wednesday—as warrants all round have became so very weak, and this rules the general market, now that warrants are again coming more in competition with makers' iron. Not long ago Cleveland warrants could not be had under 36s. 6d., and at the close of last week were not below 36s., but on Tuesday they dropped to 35s. 8d., and on Wednesday to 35s. 6d. In the face of this and of as large a fall in Scotch and hematite warrants, it could hardly be expected that prices of makers' iron could be kept up. Very little iron is being taken out of the public stores, whereas a large quantity might have been expected, seeing that No. 3 is so scarce, and that large shipments are being made. The exports have considerably improved to the Continent, but as this is the last month of the northern navigation season, the despatch of the iron cannot be delayed, and those who need to get a stock in for the winter have to import it now. The pig iron exports from the Tees this month to Wednesday night were 30,035 tons, as compared with 21,050 tons last month, and 34,333 tons in the corresponding month of last year, all to 11th. No. 4 Cleveland foundry pig iron has declined to 35s., and grey forge—which has once more become almost a drug on the market, there being so much more offered for sale than is required—can be bought at 33s. 9d., a price which will not pay the producers. If the old differences in prices were maintained, grey forge should be only 1s. cheaper than No. 3, whereas it is 2s. 3d. cheaper; the expense of producing it is the same. East Coast hematite pig iron is also in better supply than demand, yet there are no signs of the output being reduced, though makers' stocks must be increasing considerably, and the cost of production increases. Mixed numbers can readily be bought at 43s. for prompt delivery, and even 42s. 9d. is said to have been accepted, Middlesbrough hematite warrants having fallen to 42s. 3d. buyers. Foreign ore is dearer, some sellers asking 12s. 3d. per ton for good Rubio delivered on the Tees. Messrs. Cochrane and Co. are dismantling a furnace at their Ormesby Ironworks, Middlesbrough, and they will have four built, of which three are now in blast.

The accountants certify that the average realised price of No. 3 Cleveland pig iron during the quarter ended September 30th was 35s. 1·96d. per ton, or 3·65d. decrease upon the previous quarter, a result which is disappointing, as most people had looked for an increase, seeing that the market quotations have been higher, being 35s. 6d. in July, 35s. 10d. in August, and 36s. 4d. in September, the average for the quarter being close upon 35s. 11d. It is evident that the makers must have had on hand a lot of low-priced contracts. Wages of blast furnacemen for the current quarter have been reduced half of 1 per cent. They looked for an advance, and thus they some time ago asked that the sliding scale, which would according to their notice have terminated at the end of September, should be prolonged to the end of the year.

Very little improvement can be reported in the finished iron and steel trades, but the prospects for rail makers are somewhat more promising, as orders are likely soon to be given out for India, as well as for railways at home. There seems also to be a brightening up in some of the markets abroad to which we have in past years sent large quantities of railway materials. The quotation for heavy steel rails is £3 12s. 6d. net at works. Steel billets are in good request, and several cargoes have been sent to the Manchester district by sea, it being cheaper to do that than to forward by train. The railway companies, however, rather than lose the traffic, have considerably reduced their rates, so that little more is likely to be sent by way of the Ship Canal. The chief market for steel billets is South Wales. The Darlington Steel and Ironworks have now been entirely closed, and 800 men thrown out of employment. Steel ship plates are quoted £4 17s. 6d.; steel boiler plates, £5 17s. 6d.; steel ship angles, £4 15s.; iron ship plates, £4 15s.; iron angles, £4 12s. 6d.; common iron bars, £4 17s. 6d.; and best bars, £5 7s. 6d.; all less 2½ per cent. and f.o.t.

A Staffordshire firm has been making inquiries about the Bowesfield Ironworks, Stockton. These were formerly well-known iron-plate mills, but have been idle for several years. The situation of the establishment is good, being on the left bank of the Tees, and close to blast furnaces, with shipyards not far away.

Messrs. Ropner and Sons, whose shipyard has been closed for three months, have this week recommenced operations, but have not yet found work for more than half the number they usually employ.

Mr. J. W. Willans, of Dolforgan Hall, Kerry, electrical engineer, has been accepted as the Liberal candidate for the Montgomery Boroughs. Mr. Willans was for many years engineering manager at the Tees-side Iron and Engine Works, Middlesbrough, and since then has had a good deal to do with the construction of the Liverpool Overhead Railway. The Skerne Steel and Wire Company, Darlington, is about to be reconstructed. It is being wound up voluntarily, so that the share capital may be reduced. The depression of trade and the moulders' strike in particular led the directors to consider the course now adopted to be desirable.

A meeting of promoters held at Manchester has decided that the Bill for the new through line between Manchester, Newcastle, and Glasgow shall be proceeded with in the parliamentary session of 1895, and Newcastle was chosen as the headquarters of the provisional committee. A very favourable report on the proposed line of route has been received from several engineers in the country. It is stated that the North-Eastern Railway Company is contemplating the extension of the Richmond branch up the Swaledale Valley as far as Muker.

The strike of patternmakers in the North of England—which has been in progress since April 5th—is not yet settled, and the men seem to be as loth as ever to recede from their demands. They decline to follow the example of the moulders, and allow their dispute with the employers to be adjudged by arbitration or conciliation; and nothing will content them but the full advance which they demanded half a year ago. Some of the masters have obtained men from Scotland, but the strikers have induced them to return. The district is suffering greatly yet from the effects of the late moulders' and engineers' strikes, and some steamers which might have been completed four or five months ago are still waiting for their engines.

The newly added south and west wings of the Durham College of Science at Newcastle were opened on Tuesday by the Mayor of Newcastle. It is twenty-three years since the College was opened. It was in 1887 that the first wing of the present building was erected, and the building will be complete when the north wing is opened, on which occasion the King of the Belgians is to be invited to perform the ceremony. On Tuesday an experimental engine of 200-horse power was presented to the College on behalf of the Worshipful Company of Drapers, by Mr. Robert Thompson, past-president of the North-East Coast Institution of Engineers and Shipbuilders.

On Tuesday, at the invitation of the Bishop of Durham, a number of gentlemen representing labour and capital met at Auckland Castle to talk over the limitation of competition with regard to the "living wage" and cognate subjects. The conference was private, but it is stated that Professor Marshall, who takes a great interest in these subjects, gave those present the benefit of his advice.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE has been a fair business in pig iron warrants, but the tone of the market has been easier, and the tendency of prices downward. As the miners' strike has now practically collapsed, there is no chance of the prices current of late for pig iron being maintained, and holders are understood to have been selling. Scotch warrants have further declined about 6d. per ton. The price of Cleveland iron is also down 5d. per ton, and Cumberland hematite has fallen in proportion. Only a small business has been done in hematite, although it is certain that the consumption will henceforth increase.

Since last report three furnaces have been put in blast at Gartsherrie Ironworks, and the prospect is, that in a short time a further considerable increase will be made.

The prices of makers' pig iron are as follows:—G.M.B. f.o.b. at Glasgow, No. 1, 44s.; No. 3, 42s. 6d.; Monkland, No. 1, 48s.; No. 3, 42s. 6d.; Carnbroe, No. 3, 46s.; Summerlee, No. 1, 59s.; No. 3, 52s.; Coltness, No. 1, 59s.; No. 3, 51s. 6d.; Calder, No. 1, 58s.; No. 3, 50s. 6d.; Glengarnock at Ardrossan, No. 1, 54s.; No. 3, 49s. 6d.; Eglinton, No. 3, 43s.; Shotts at Leith, No. 1, 58s.; No. 3, 52s.

The shipments of pig iron from Scottish ports in the past week amounted to 2236 tons, compared with 5035 in the corresponding week of last year. India took 25 tons, South America 50, Australia 15, Italy 150, France 15, Germany 220, Holland 216, Spain 65, other countries 20, the coastwise shipments being 1460, against 1105 tons in the same week of 1893.

The stocks of Scotch pig iron are reduced to very small proportions at the ironworks, and those in the warrant stores show a decrease for the week of about 1000 tons.

Work is now being gradually resumed at the malleable iron and steel works, the managers proceeding with caution, as they are obliged to have cheap fuel. The prices obtainable will not afford anything else. It is a matter of uncertainty as to the amount of employment to be immediately available in finished iron and steel. The interruption to shipbuilding during the strike has been only partial, because supplies of steel were always to be had from the North of England, and merchants were thus able, wherever it was absolutely necessary, to carry out their engagements. Prices are not very regular, but they may be expected to equalise themselves in the course of the next two or three weeks.

The shipments of iron and steel manufactured goods from Glasgow in the past week embraced sewing machines to the value of no less than £10,825, of which the greater proportion went to the Continent; other machinery, £7743; steel goods, £2456; and miscellaneous iron goods, £11,792.

The coal market is now assuming something like its usual appearance, although a few weeks must still elapse before the full supply of coal will be attainable. Orders for cargoes from the North of England are now no longer given. On the other hand, the shipments of Scotch coals are on the increase, and the prices are receding. In the Glasgow district the best all-round coal is quoted at 9s., second quality 8s., and dross 5s. per ton.

The colliers' strike has quite collapsed in Lanark and Ayr. Fife and a part of Stirling and the Lothians still hold out, but the men must now be fully aware that their cause is utterly hopeless.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE colliers, having given in their notice, have now put aside, apparently, all discussion for a time, and continue working very regularly, with the exception of a few partial strikes. The General Federationists are, however, not inclined to let the opportunity slip by, and it may be taken for granted that the coming winter will see a lot of platform work, the agents of the English organisation making every effort to annex the Welsh colliers. I have spoken to influential men amongst the local colliers, and though they cannot guarantee the action of the hauliers, they think the middle-aged and common-sense colliers will strongly oppose any union with England.

The coal trade has entered upon the fourth quarter in a way to arouse very satisfactory comments. It is evident that war rumours, and the necessity of keeping the British fleet on the alert and ready to protect our interests abroad, tells favourably on the steam coal trade, and coaling stations are being well supplied. Some large tonnages went out this week. The total last week from Cardiff ports, notwithstanding the monthly holiday, was 280,000 tons. I note that the great steamship and other companies are beginning to make their arrangements for next year's contracts. The P. and O., as usual, are moving, and invite tenders for 120,000 tons.

On 'Change Cardiff the prominent topic of conversation of late has been the prominent figure at which contracts will be entered into, and from all I can glean, seeing what prices are had, and the firmness of the market, and noting also the prospects and the possibilities of the future, a likely price will be from 11s. to 11s. 6d. A good authority on 'Change agrees with this, though if the Foreign-office became actively disturbed during the next week or two, the higher figure might be exceeded.

The latest quotations this week, Cardiff, are as follows:—Best steam, 11s. 9d. to 12s., demand good; seconds, 11s. to 11s. 6d.; best Monmouthshire, 10s. 6d. to 11s.; dry coal, from 10s. f.o.b. House coal continues in a vigorous condition, and home and outside demand is good. Best continues at 11s.; No. 3, Rhondda, 10s. 3d. to 10s. 6d.; No. 2, Rhondda, 8s. 9d.; through, 6s. 9d. to 7s.; small, 4s. 9d.

Newport and Swansea coal exports remain good, and prices firm. Swansea quotes best steam at 11s., and anthracite from 8s. 9d. to 12s. 6d., according to quality. For this class of coal, and for the kind which yields a useful blending of bituminous and anthracite, the inquiry is good, and I hear, in respect of the latter, that developments are likely at Hirwain on a large scale.

Coke remains tolerably firm, and I note that the closed steel works of Tredegar and Rhymney are busy in that direction. Cyfarthfa in the fulness of its requirements lending a helping hand.

Present quotations, Cardiff, are:—Furnace, 15s. to 16s.; foundry, 17s. to 18s.; special foundry, 20s. to 20s. 6d. Patent fuel is on steady demand at last prices, 11s. to 11s. 6d. Swansea price, 10s. 6d. to 11s. Pitwood, 15s. 6d. Cardiff; 17s. Swansea.

There has been little change from the ordinary rut in the iron and steel trades, and the activity one meets with here and there is more of the nature of preparing for briskness than meeting increased demands. The quantity of ore coming in and stocked at the principal works continues very large. So also in the make of tin bar, which has been heavy, particularly at Cyfarthfa. On two occasions this week the despatch sent, principally to the Great Western sidings, has been unusually large. On one day 50 wagons, principally ten tons each, were sent away.

I note that at these works the storing of pig iron has been immense of late, and every available corner utilised. Several hundred tons of refinery iron, which had been stocked for years, have also come under the Cyfarthfa tactics of putting everything to good purpose. This iron was of excellent brand, and to bring it to account a short railway was put down, and the whole rapidly cleared.

Pig iron continues to come in from Middlesbrough and Millom. Only two cargoes of rails have been despatched this week—one of 750 tons to Spain, and another, Great Western rails, to Highbridge, 110 tons.

Market quotations, Iron and Steel Exchange, Swansea, were as follows, midweek:—Glasgow warrants, 42s. 6½d.; hematite, Middlesbrough, 42s. 7½d.; Welsh bars, £5 to £5 2s. 6d.; steel rails, heavy, £3 15s. to £3 17s. 6d.; quotation at Cardiff, £3 12s. 6d. to £3 15s.; light, Swansea, £4 10s. to £4 15s.; steel sheets, £6 5s. to £6 7s. 6d.; sheet iron, £6 to £6 10s.; Bessemer steel tin-plate bars, £4 to £4 2s. 6d.; Siemens best, £4 to £4 2s. 6d. Tin-plates: Bessemer cokes, 10s. 3d. to 10s. 6d.; Siemens, 10s. 6d. to 10s. 9d.; ternes, per double box, 28 by 20, 20s., 21s., 22s., 24s.; best charcoal, 12s. to 12s. 6d., according to finish of brand; wasters, 6d. to 1s. less than primes.

Block tin is down to £69 5s. There have been large clearances of tin-plates against Swansea; but tonnage has not come in as expected, or they would have been heavier. The total received from works last week amounted to 66,167 boxes; total shipped, 57,766 boxes, leaving stocks at 235,712 boxes.

The shipments of September were very satisfactory, 13,882 tons to the United States and 4374 tons to Russia, as against 9906 tons to the States and 3817 to Batoum for September, 1893.

A good deal of satisfaction is felt at the healthy state of the Swansea harbour trade. September beat the record. In imports there was an increase of 23,408 tons, and in exports 35,216 tons. During the month, in iron ore and in iron and steel, the increase in imports was large. Last week Swansea imported 1516 tons pig and 290 scrap steel, and a large quantity of tin-plate from the Monmouthshire district. In patent fuel there would have been a large clearance had tonnage come in. As it was exports were confined to 2470 tons to France, 1200 to Roumania, and 1000 tons to Algeria.

The great question now "on" at Cardiff is, Shall the Corporation acquire the Bute Docks and Penarth, possibly Barry, and form a harbour much the same as Swansea; but it would seem likely that while the Council are discussing payment to experts, and ways and means generally, the opposition will grow stronger. Some of the moderate men hold, that with a costly waterworks scheme, carrying out electric lighting, and acquiring tramways, they have enough on their hands at present. On Wednesday it was stated on good authority, that the Taff Vale Railway Company has decided to withdraw from the scheme, and up to the date of my despatch this has not been corrected. The impression in Cardiff is, that if the statement is right—and it seems reasonable, as without Penarth the Taff would have no sea outlet—the Corporation will retire from the undertaking.

In Swansea a water action, for which a claim of £60,000 was made, has been settled for £10,833 by arbitration in London.

The first main line train was run by the Rhondda and Swansea Railway directors over the new extension into Swansea on Tuesday, they having first inspected the whole work of the railway, including the swing bridge over the Neath river. The connection from the Rhondda is now unbroken with the exception of a few yards at Briton Ferry.

The Llanelly Harbour Commissioners held an important meeting this week, and comments were passed on the dilatory character of the Board of Trade in not sanctioning the improvements desired. Doubtless this will take a practical form next week.

A conference of collier delegates is to be called to enter into the question of the use of carbonite instead of compressed gunpowder in blasting operations. It is contended that though the use of carbonite is safer than powder, the miners are not able to earn so much, and that in consequence they should have compensation.

The formation of a transport company for the Severn Navigation is proceeding vigorously, and Sir W. T. Lewis has announced to the promoter that the Bute Docks Board are prepared to support, financially and otherwise, the scheme of a water transport company. In this, traders at Cardiff and Worcester are benefited, and the building of suitable steamers will be one of the earliest efforts.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE position of the iron and steel trade over here has in no wise altered since last week, a limited business being done in most departments, while quotations are rather fluctuating, and certainly anything but satisfactory. Quietness still prevails in most branches of the Silesian iron trade. Pig iron is in particularly weak request, and the blast furnace works justly complain of the decreasing tendency in prices, which has been very keenly felt in some instances. In malleable iron very little is done just at present, and for the few orders that are being secured here and there extremely low quotations have to be accepted.

With reference to the Austro-Hungarian iron trade, nothing of interest can be reported to have occurred since last week. Makers and manufacturers, on the whole, are well employed, though here and there a slackening off in demand has been noted lately. Pig iron continues to be scarce, and there is generally much firmness exhibited in prices. Few orders are coming in for bars, which may be accounted for by the exceptionally brisk demand that was coming forward for that article in last quarter, when dealers as well as consumers were anxious to profit from the low prices then ruling; for the present there is little chance for an improvement in demand, unless stocks should begin to decline. The steel trade is altogether in a poor condition, owing to the scarcity of orders for rails and railway rolling stock. The machine and wagon shops are in comparatively fair employment, twenty express locomotives having been ordered by the Austrian State Railways.

In France a rising demand can be noticed for almost all sorts of iron, though orders of weight are, as yet, rather scarce, but downward movements have not been reported for some time past. On the contrary, there is a very firm tone perceptible in most departments. A hopeful feeling generally prevails, and in many quarters the belief is entertained that a fairly good winter's business will be done.

The Belgian iron trade begins to show slight signs of a revival, and a firm tendency is generally reported. For the present, however, makers "live in hope," the business actually done being of small weight, but the more sanguine persons are of opinion that the worst is past, and that a general and lasting improvement is about to take place. Up to date both the raw and the finished ironworks are but moderately engaged; export trade continues uncommonly weak, and there are very few works that can boast of any forward orders. The Company Cockerill has been fortunate in securing a pretty fair order for fish-plates for the Roumanian Government at 147·50f. p.t. at works.

There is nothing new to note with regard to the Rhenish-Westphalian iron and steel industry. Some branches are tolerably well employed, and the fact that prices are rather firmly maintained is generally considered as a symptom of lasting improvement. The quietness in the iron trade cannot fail to have a strong influence on the iron ore market, and there is but little activity to be noted at the iron ore mines. Since previous letters no alteration in quotations can be reported to have taken place, nor is it at all likely that there will be any material change so long as the weakness in the pig iron department continues. From the malleable iron market tolerably good accounts have been coming in upon the week, though little actual business is done in most branches; but a good number of inquiries have come in for bars as well as for hoops, and buyers appear to be just a little less reserved than formerly. In girders not much has been done lately. A good activity continues at the plate and sheet mills, but makers find it impossible to carry an advance in quotations. Foreign inquiry is dull, sheets only meeting with a pretty strong request. Drawn wire and wire nails still show no sign of improvement, either in price or demand; and there is likewise a very weak tone to be noticed in the rivet business. The ironfoundries and machine factories are only poorly employed, while a good activity continues at the wagon shops.

A concession for the building of a locomotive wagon and rail shop in Russia has been granted by the Russian Government to an American syndicate, under condition that twenty-four foreigners, at the most, are to be employed, and that only Russian raw material is to be consumed.

The following figures, showing the average prices of pig iron in the different countries, may perhaps be of some interest. The highest prices for raw iron are quoted in Italy, where 161f. p.t. is paid for common foundry pig. In Russia 104f. p.t. is quoted; in Austria, foundry pig is paid with 92f.; in Hungary, 90f. p.t. In Japan, 84f. p.t. is quoted; in Spain, 69f. p.t.; in Norway, 69f. p.t. In Luxemburg, 45f. p.t. is the price quoted; in Belgium, 51f.; and in Bavaria, 57f. p.t. is paid. In the United States 71f. p.t. is the average price for foundry pig, Prussia and France each quoting 61f. p.t.

STATUE TO SIR WILLIAM PEARCE.—A memorial statue of the late Sir William Pearce, Bart., the eminent shipbuilder, who died in London, December 18th, 1888, was unveiled at Govan, Glasgow, on Saturday, the 6th inst., by Lord Kelvin. The event took place in presence of a large concourse of spectators for most part composed of the trades' societies belonging to Govan, and of employés in the shipbuilding works. Besides Lord Kelvin, there were present, Lady Kelvin, Lady Pearce, Sir Wm. George Pearce, Lady Roberton, Sir James Bain, the Provost and Council of Govan, and Rev. Dr. John MacLeod. The statue, which has been erected at a cost of some £2000, defrayed by public subscription, occupies a commanding and central position near the cross of Govan, the site having been given by Lady Pearce. The statue proper is from the design of Mr. Onslow Ford, of London, while the massive and lofty pedestal on which it stands is of polished Peterhead granite, supplied by an Aberdeen firm. The pedestal alone weighs about 25 tons, and is 12ft. 6in. high. On the upper base dado are four sunk moulded panels for inscriptions and memorial tablets. The statue represents the late baronet examining the plan of a ship, and the likeness fully maintains the reputation of the sculptor. A glass vase deposited inside the base of the pedestal contains drawings of some of the famous steamships built under the deceased baronet's management, including the Arizona and Alaska, together with a full list of the vessels built during his time; a pamphlet entitled "The Building of a Ship;" a map of the borough of Govan, photographed by the late baronet; current coins of the realm, copies of newspapers, &c. In unveiling the statue, Lord Kelvin gave a lengthy biographical statement regarding the late baronet, and said that by the statue now unveiled they would be kept in remembrance of what Sir William Pearce had done for Govan, for the Clyde, and for the world. Sir W. G. Pearce followed Lord Kelvin, and formally handed over—on behalf of his mother—the title deeds of the ground on which the monument had been erected.

## AMERICAN NOTES.

(*From our own Correspondent.*)

New York, October 5th.

The expectation of the early placing of large orders for billets, pig iron, bridge plate, steel rails, and cast pipe has had a favourable effect on the pig market. Pig iron production is increasing at the South, and large sales were made this week of mill irons at Ohio River points. Specifications for considerable bridge workers expected in a few days. The anxiety for winter orders is leading to the shading of prices. Wire rods and barb wire are in good demand. The rush for nail orders led to another cut of 5 cents. Sheet iron and boiler plates are doing better than for two months. Work will be hurried through on projected tin-plate mills, and despite the refusal of the workmen to accept a 25 per cent. drop, a sufficient cut will be made to protect the bulk of the home trade, especially in ternes. Several large users of billets made offers this week for three months' supplies, but acceptances have not been announced. Girder rails are active. The railroad demand for structural material will soon improve. The money markets are easy. For shop and factory work there is a gradual increase of orders, but no great expansion of trade is probable until the opening of spring.

## LAUNCHES AND TRIAL TRIPS.

The s.s. Turret Bell, turret deck steamer, was taken on her official trial on Thursday, the 4th inst., when a mean speed of 11¼ knots was registered, her total deadweight capacity being 3800 tons on 19½ft. draught. She has been built by Messrs. William Doxford and Sons, of Sunderland, to the order of the Turret Steam Shipping Company, Newcastle—Messrs. Petersen, Tate and Co., managers—and has received the highest class in both British Corporation and Bureau-Veritas Registries.

## EXPERIMENTS ON THE DISINFECTION OF TOWN SEWAGE WITH SULPHURIC ACID.[*]

By Dr. M. Ivanoff.

The fact that the cholera-bacillus displays an intense susceptibility to the action of acids was known to its discoverer, for Dr. Koch pointed out that in the acid secretions of the stomach these bacilli speedily lose their vitality. The subsequent experiments of Kitasato have shown that very minute additions of sulphuric and hydrochloric acids to bouillon cultures destroy cholera germs in the course of a few hours; and, lastly, Messrs. Stutzer and Burri have studied exhaustively the effect upon these organisms of very dilute solutions of sulphuric acid. At the suggestion of Professor Pfuhl, the author undertook to investigate the action of dilute sulphuric acid upon cholera-bacteria when present in sewage water. From the inception of his experiments he surmised that under these conditions the acid must be used in a more concentrated form than in the above cases, because the sewage water invariably contains substances which would combine with the acid, and would thus, to some extent, neutralise its effects. It was, however, ascertained that the additional amount of acid rendered necessary on this account was but trifling. The samples of sewage water were derived both from the Berlin and the Potsdam sewers, and were infected alternately with pure cultures of the cholera-bacillus and with the fresh dejections of a cholera patient. The acid in the case of the Berlin sewage water was used in three degrees of strength: (1) as a 0·02 per cent. solution; (2) as a 0·04 per cent. solution; and (3) as a 0·1 per cent. solution. The conditions under which the analyses were made are fully described, and the author availed himself of microscopic observations, as well as bacteriological tests. Four parallel series of experiments were carried out, and the results were in every case identical. The Potsdam sewage, which is three times as concentrated as that of Berlin, was treated with stronger acid, viz., with 0·04, 0·06, 0·08, and 0·12 per cent. solutions. It was found that in the case of the Berlin sewage the 0·04 per cent. solution of acid was fatal to the cholera-bacilli, but that with the stronger sewage water of Potsdam the amount of acid needed was that present in the 0·08 per cent. solution. It is pointed out that, whereas previous to treatment the sewage water was faintly alkaline, the sample to which 0·08 per cent. of acid had been added had a strongly acid reaction on being tested with litmus paper, and that such reaction may be regarded as an indication that the necessary dose of acid has been employed. This treatment is, with the exception of the use of lime, the cheapest system that can be adopted.

Siemens Brothers' Electrical Works. — The last vacation visit of the Society of Engineers for the present year was made on Tuesday, when the president, Mr. G. A. Goodwin, and about 70 members, inspected the electrical engineering and submarine cable works of Messrs. Siemens Brothers and Co., at Charlton. The first department visited was the new dynamo shop, which is fitted up with all the latest appliances for turning out this class of work. Much interest was shown in the cable shop where deep sea and electric lighting cables are made. Some of the cables for the latter purpose are very heavily armoured for laying in the ground in Edinburgh without pipes or protecting channels. The central power and lighting station attracted considerable attention, as nearly the whole of the works are now being driven by motors instead of scattered engines, and the engines have been taken out. The station contains engines and dynamos for producing the current for driving machinery and lighting the works. The driving is done by 54 electric motors distributed through the works. We shall refer more at length to this in another impression.

18,307. Detachable Lids of Jugs, A. Martin, Staffordshire.
18,308. Range and Position Finders, W. M. Huskisson, London.
18,309. Mantles for Incandescent Gas Lights, H. Blücher, Manchester.
18,310. Weaving Apparatus, W. Simpson and the Duplex Weaving Appliance Company, Manchester.
18,311. Machine for Extracting Vegetable Fibres, N. Ismaljee, Manchester.
18,312. Cutting Wood, W. Whitley, Keighley.
18,313. Marine Signalling, J. Wall, Liverpool.
18,314. Casks, J. W. Mellor, Oldham.
18,315. Storage Buildings for Coal, T. Wrigley and T. Taylor, Manchester.
18,316. Cotton Reels for Holding Needles, G. Grigioni, Liverpool.
18,317. Art Decoration, M. English, near Clevedon.
18,318. Reciprocating Motions, J. Sturrock, Dundee.
18,319. Passenger Guard for Omnibus, E. Pink, London.
18,320. Machines for Digging Potatoes, J. Holt, Cheshire.
18,321. Apparatus for Tilting Casks, P. S. Lawless, Dublin.
18,322. Separating Cream from Milk, J. V. Geary, Dublin.
18,323. Close-jointing Chair Frames, J. Gaymond, Manchester.
18,324. A Pneumatic Billiard-table Cushion, J. C. Murray and W. McI. Valentine, Breccin.
18,325. Hydraulic Cranes, J. A. Saner, Liverpool.
18,326. Hydrocarbon Lamps, B. Cars, London.
18,327. Steam-generators, J. J., T. F. and J. W. Meldrum, Liverpool.
18,328. Duplex Telegraphy, G. E. Fletcher, Stockport.
18,329. Domestic Filters, W. H. Barr, Manchester.
18,330. Reversible Cloth, W. Buchanan, Glasgow.
18,331. Rotary Water Meters, H. J. Rohlf, Glasgow.
18,332. Attaching Inflators to Cycles, J. Stradling, Newbury.
18,333. Driving Gear of Rear-driving Cycles, W. J., E. Freeman and R. Thompson, London.
18,334. Window Lock, J. Wharfe, London.
18,335. Boots and Shoes, F. Kennel, London.
18,336. Utilising Tidal Power, W. J. Roberts and J. R. Jones, Liverpool.
18,337. Frozen Meat, J. Atherton, Liverpool.
18,338. Soldering Irons, J. R. Cooper, Birmingham.
18,339. Carbons for Electric Lamps, E. G. Acheson, London.
18,340. Trousers, J. M. Forster, London.
18,341. Soles of Boots, F. Leigh and G. Padmore, jun., London.
18,342. Saddles, P. Taaffe, London.
18,343. Bridles, P. Taaffe, London.
18,344. Horse-collars, E. E. Kelsey, London.
18,345. Filling Stoppered Bottles, E. Butes, London.
18,346. Apparatus for Supplying Fluid, O. Beck, London.
18,347. Hinge Folding Splashboard, C. Irvine and G. Dyer, Belfast.
18,348. Spring Bottoms for Beds, &c., T. A. Stoll, London.
18,349. Felt Handles for Cycles, F. G. Bensly, Birmingham.
18,350. Trays of Wardrobes, G. W. Raikes, Birmingham.
18,351. Starting Gear for Vehicles, J. B. Lee, London.
18,352. Indicating the Names of Stations, G. P. and E. A. Wadsworth, and H. I. Hankin, London.
18,353. Focussing Images in Cameras, L. H. Chase, London.
18,354. Motive-power Engines, E. Edwards.—(*O. Pick, Belgium.*)
18,355. Cycles, W. E. Corrigall, London.
18,356. Station Indicators for Waiting-rooms, A. A. Jeenel, London.
18,357. Pneumatic Cushion in Boot Soles, J. H. Betteley and F. W. Phillips, London.
18,358. Treatment of Starch, H. C. E. Wilmot, London.
18,359. Elevating Mechanism, B. Wilcox.—(*The Eisenwerk, Germany.*)
18,360. Blocking and Cutting Presses, N. J. Hill, jun., London.
18,361. Plates for Printing, G. Isaac, London.

*28th September*, 1894.

18,362. Spur Protector, D. J. Coyne and T. Christian, London.
18,363. Earthenware, R. Jackson and J. H. Carter, Sheffield.
18,364. Hinge for Doors of Cesspits, &c., G. Waller, London.
18,365. Boilers, L. P. Perkins and G. F. Buck, Manchester.
18,366. Machinery for Making Felt, C. Aris, London.
18,367. Box with Powder Puff, A. W. Shirley, London.
18,368. Envelope Book, E. H. Wilson.—(*J. H. Hunter, Argentine Republic.*)
18,369. Gas Producer, G. Threlfall and R. J. Hodges, London.
18,370. Buttons for Gloves and Dresses, J. Paterson, London.
18,371. Mechanical Counter or Indicator, C. Jost, Manchester.
18,372. Minimising the Effect of Shots, W. Powell, London.
18,373. Buckle for Animal Harness, E. Roberts, Longport.
18,374. Tacking Machines for Boots, W. H. Dorman, Stafford.
18,375. Internal Combustion Engines, W. J. Crossley, Manchester.
18,376. Rotary Pumps, G. Marty, Manchester.
18,377. Nut Locking Plate, H. J. Fuller, Dublin.
18,378. Safety Watch-holding Glove, H. Robinson, Bradford.
18,379. Cooking and other Ovens, H. J. B. Holland, Blackburn.
18,380. Wind and Rain Excluder, W. Walks, Bradford.
18,381. Boot Protectors and the like, A. Smith, Glasgow.
18,382. Gas Fires, J. J. Wilson, Glasgow.
18,383. Couplings for Railway Wagons, A. and H. Ingram, Liverpool.
18,384. Ventilating Apparatus, W. J. Thomas, London.
18,385. Brake for Vehicles, J. R. Kyme.—(*G. Kyme and P. G. Williams, Australia.*)
18,386. Velocipedes, H. W. D. Ingram, Birmingham.
18,387. Ladies' Hair Dressing Pin, G. A. Morgan, Cardiff.
18,388. Railway Carriage Seats, J. J. Duffy, Dublin.
18,389. Wheels for Vehicles, S. T. Richardson, A. Smallwood, and R. Price, Birmingham.
18,390. Chain Wheels for Cycles, J. Appleby London.
18,391. Feeding Bottles, H. Hermann, Liverpool.
18,392. Controlling Water Supply, A. Campbell and W. C. Sim, Bristol.
18,393. Grates of Looms for Weaving, J. W. Banister, Halifax.
18,394. Disinfecting Cisterns, C. O. Williams and J. Stotter, London.
18,395. Vehicle Wheels, W. Pain and L. Sargent, London.
18,396. An Improved Dress Holder, E. S. Collins, London.
18,397. Fictile-ware, The Worcester Royal Porcelain Company, Ld., W. M. Binns, and G. H. Hancock, London.
18,398. Classifying Ores, J. Hosking, London.
18,399. Elastic Wheels, R. Thom and J. Watt, Aberdeen.
18,400. Chairs, A. E. Carrie, London.
18,401. Gas Pliers, J. R. Cooper, Birmingham.
18,402. Fly-wheel, G. Sharman, Birmingham.
18,403. Clutch Pulleys, W. P. Chapman, Birmingham.
18,404. Chimney Cowls, T. Schröder, London.
18,405. Frizzling Hair, H. T. Turner, London.
18,406. Weighing Apparatus, E. Maibaum, London.
18,407. Preventing Ladders Slipping, J. Arnott and J. Skirrow, London.
18,408. Tobacco Pipes, R. V. Burt, London.
18,409. A New Game, M. L. Dorrington and J. S. Trott, London.
18,410. A New Cartridge Belt, A. M. E. Summer, London.
18,411. Dress Fasteners, A. Turner, London.
18,412. Cigar Tray, H. Ost, London.
18,413. Rope Horseshoes, M. Müller, London.
18,414. Locomotive Gear, J. F. Toomer and G. C. Morton, London.
18,415. Car Couplings, J. Shearn, London.
18,416. Drawing Off Beverages, A. Soames, London.
18,417. Gasholder Guide Carriages, S. Cutler, London.
18,418. Automatic Self-opening Umbrellas, G. Ross, London.
18,419. Tires, W. Dodd, London.
18,420. Securing or Holding Persons, J. J. Wilson, Birmingham.
18,421. Drying and Airing Clothes, C. Holmström, London.
18,422. Washing Powder, S. Rasenblum and F. Bartelt, London.
18,423. Ledger Markers, G. C. Marks and E. Ellisden, London.
18,424. Washing Machines, W. Gibbins, Leytonstone.
18,425. Extracting Metals from Ores, J. Mactear, London.
18,426. Lamp Shade and other Wire, J. Wright, London.
18,427. Electric Traction, M. Hutin and M. Leblanc, London.
18,428. Cans for Conveyance of Milk, W. Cooper, London.
18,429. Preparing Diazo Salts for Dyeing, A. Feer, London.
18,430. Bobbins and Reels for Weaving, W. Webster, London.
18,431. Lock-nut, J. Newns, London.
18,432. Pocket Calendar or Indicator, E. S. Cadman, London.
18,433. Tackle Blocks, A. J. Boult.—(*F. X. Rousseau, United States.*)
18,434. Disinfectors, A. B. Reck, Liverpool.
18,435. Purification of Beer, A. J. Boult.—(*A. Delhaise, Belgium.*)
18,436. Lighters, W. J. Chambers and R. Williamson, Liverpool.
18,437. Weaving Shuttles, A. J. Boult.—(*W. Wagenknecht, Germany.*)
18,438. Stirrups, W. E. Schenk, London.
18,439. Signalling Apparatus, L. B. Stevens, London.
18,440. Gas Washing Apparatus, S. Hersey and Kirkham, Hulett, and Chandler, Ld., London.
18,441. Gas Washing Apparatus, Kirkham, Hulett, and Chandler, Ld.—(*F. D. Marshall, Denmark.*)
18,442. Colour Printing Apparatus, J. Bachelerie, London.
18,443. Apparatus for Using Liquid Fuel, S. H. Terry, London.
18,444. Safety Mechanism for Lifts, J. S. H. Drew, London.

*29th September*, 1894.

18,445. Gas Generating Plant, B. H. Thwaite, London.
18,446. Rope Grip, J. W. and J. J. Taylor and F. Broadbent, Oldham.
18,447. Extinguishing Lamps, W. Pearce and A. J. Mason, Birmingham.
18,448. Washing Bottle Stoppers, F. A. Bird, Birmingham.
18,449. Braces Attachments, T. Walker and J. J. Glasgow, Birmingham.
18,450. Cycle Brake Attachments, A. Blackwell, Birmingham.
18,451. Funnel, G. F. Fitter and J. Burley, Birmingham.
18,452. Oil Engines, P. P. Bedson and J. C. Hamilton, Glasgow.
18,453. Arm Chairs and Appliances therefor, A. Plant, Glasgow.
18,454. Manifold Books for Use as Post Cards, A. H. Megson, Manchester.
18,455. Preventing Scratching of Polished Surfaces, F. Smith and H. T. Heath, Bristol.
18,456. Window Blind Furniture, W. Lowe and C. Britton, Birmingham.
18,457. Coupling, &c., Railway Vehicles, C. Wright, London.
18,458. Door Lock, W. Anderson and S. Stott, West Hartlepool.
18,459. Appliances for Curling Hair, G. H. Twigg, Birmingham.
18,460. Refrigerators, T. Sharratt, Derby.
18,461. Valve, W. E. Bryan, Lyndhurst.
18,462. Taps for Chemical Fluids, T. W. F. Cherry, North Shields.
18,463. Method of Advertising, H. R. Dixon, Manchester.
18,464. Cycle Lamps, F. Powell and F. Hanmer, Birmingham.
18,465. Pneumatic Tire Covers, R. W. Edlin and R. Green, Birmingham.
18,466. Bamboo Bicycle Frames, R. W. Smith, Birmingham.
18,467. Bicycles, J. Talbot, Wellington, Salop.
18,468. Making Felt Forms for Toys, T. M. Cockcroft, Leeds.
18,469. Manufacture of Linoleum, &c., J. Igleby, Leeds.
18,470. Soles of Boots, Shoes, and Slippers, W. L. Dash, London.
18,471. Flushing Water-closets, D. Mitchell, Dundee.
18,472. Damping Appliances for Letter Copying, M. S. Stevenson, Glasgow.
18,473. Lamps, M. S. Stevenson, Glasgow.
18,474. Nose-bags for Horses, R. Wright, Glasgow.
18,475. Chip Cutting Machinery, R. T. Heselwood, London.
18,476. Opening Window Sashes Inwards, T. Black, Glasgow.
18,477. Automatic Delivery Machines, E. P. Wicke, London.
18,478. Casements, W. Youlton, London.
18,479. Fixing Castors to Chair Legs, W. G. Tubb, London.
18,480. Electric Gaslighters, W. N. Jaskey and E. S. Else, London.
18,481. Motors Driven by Compressed Air, C. Bono, London.
18,482. Steam Pressure Indicators, J. Beswick, London.
18,483. Boot, Shoe, and Corset Laces, D. G. Lewis, London.
18,484. Apparatus for Unloading Ships, W. Parr, London.
18,485. Watering Cans, E. T. Gamble, London.
18,486. Door Bolts or Fastenings, O. H. Steed, jun, London.
18,487. Teat, H. Carter, Horwich.
18,488. Pneumatic Swing Razor Strop, T. Reynor, Dublin.
18,489. New Fire Escape, S. Simpson, Blackburn.
18,490. Underground Railway Construction, H. Grauel, London.
18,491. Book Protector, G. Barnes, Birmingham.
18,492. Horse Shoes, A. S. Walker, London.
18,493. Flower Trays, T. M. Ellis, London.
18,494. Surface Exhibitors, V. P. de Knight, London.
18,495. Picture Frames, G. M. Dodshon, London.
18,496. Explosive, F. W. Bawden, London.
18,497. Polishing Tools, A. J. Boult.—(*C. Bruart and L. Lombot, Belgium.*)
18,498. Protector for Pins, C. J. Gerry, Liverpool.
18,499. Chain for Cycles, M. Boudard and H. A. Shelton, London.
18,500. Movable Partitions, G. Thornborough and J. Wilks, Manchester.
18,501. Incandescent, Electric Lamps, W. T. Kerr, London.
18,502. Crutches, B. B. Moss, Liverpool.
18,503. Lantern Slide Carriers, F. Bartlett, London.
18,504. Enemas, E. J. Lambert, London.
18,505. Revolving Chair-actions, E. Warren, London.
18,506. Advertising on Cycles, C. L. Lamare, London.
18,507. Electric Lampholder, C. O. Duetschmann, London.
18,508. Band Saws, A. J. Boult.—(*J. Leclerq, Belgium.*)
18,509. Manufacture of Ethers, M. Otto and A. Verley, London.
18,510. Apparatus for Enriching Gas, W. Kemp, London.
18,511. Fruit Presses, E. Edwards.—(*C. Heinle, Germany.*)
18,512. Knife Cleaner, L. A. Fidge, Gravesend.
18,513. Anchors, F. Grosvenor, London.
18,514. Oil and Gas Engines, J. N. Aronson, London.
18,515. Coating Creams with Chocolate, D. M. Holmes, London.
18,516. Manufacture of Alkylrhodonates, A. M. Clarke.—(*A. Edinger and A. Müller, Germany.*)
18,517. Ink Reservoir for Pens, C. Smith.—(*J. F. S. Wallace, China.*)
18,518. Knitted Fabrics, T. Hill and A. D. Whitehead, London.
18,519. Manufacture of Cyanides, J. Pfleger, London.
18,520. Manufacture of Alkaline Metals, J. Pfleger, London.
18,521. Churns, T. Bradford, London.
18,522. Electric Arc Lamps, W. S. Pendleton, London.
18,523. Vehicle Wheels, H. H. Lake.—(*F. Myers, United States.*)

*1st October*, 1894.

18,524. Soil-pipes for Water-closets, F. Walsh, Halifax.
18,525. Celestial Globe, R. Huntley, South Shields.
18,526. Sodium Chlorates, J. Hargreaves and T. Bird, Farnworth-in-Widnes.
18,527. Toilet Apparatus, A. M. Cadell and Z. E. Gardiner, Dublin.
18,528. Pneumatic Pads for Cricketers, G. Hodson, Dublin.
18,529. Ships' Water Draught Indicator, A. Corner, South Shields.
18,530. Carrying and Stacking Bottles, H. Slingsby, Bradford.

18,531. Emptying Bottoms of Bottles, H. C. Slingsby Bradford.
18,532. Adjusting Beer Barrels, &c , H. C. Slingsby, Bradford.
18,533. Carriage for Beer Barrels, H. C. Slingsby, Bradford.
18,534. Curtain Poles, W. G. McMaster and J. Sinclair, London.
18,535. Furnaces for Destroying Refuse, J. Gill, Bradford.
18,536. Springs for Weighing Machines, W. H. Penning, Henfield.
18,537. Liquid Drawing-off Apparatus, J. J. Clark, Cardiff.
18,538. Fire Doors for Furnaces, D. B. Morison, Hartlepool.
18,539. Toy, J. W. Wood, Nottingham.
18,540. Handles of Cycles, &c., F. Bartlcet, Birmingham.
18,541. Liquid Heating Apparatus, H. P. Miller, London.
18,542. Telegraphs, H. W. C. Cox and R. J. Crowley, London.
18,543. Lighting Pipes, G. E. Seymour and W. C. Hunniball, Thetford.
18,544. Rubber Stamp for Marking Goods, J. Howarth, Sheffield.
18,545. Fasteners for Belts, A. Dickson —(*R C. Dickson, Ceylon* )
18,546. Raising Pies, E. Frost and G. Holbrook, Longport.
18,547. Tire Valves, W. Bown, G. Capewell, and H. W. D. Ingham, Birmingham.
18,548. Additions to Toe-clips, J. Harrison, Birmingham.
18,549. Mattress to be Used as a Table, B. Franke, Manchester.
18,550. Cartons, C. N. Rickinson, London.
18,551. Exhaust Displacer, F. M. and E. J. Davis, Birmingham.
18,552. Automatic Pot for Coffee, &c., C. Martin, London.
18,553. Pipe Joints, F. W. Kent, London.
18,554. Box or Package for Butter, &c., E. Pontin, London.
18,555. Billiard Tables, H. H. Greaves and J. Salisbury, Manchester.
18,556. Slate Frames, D. Macdonald, London.
18,557. Parallel Rulers, J. Thomas, London.
18,558. Copying Presses, C. J. Davison, London.
18,559. Electric Conductors, &c., A. W. Gamage, London.
18,560. Chain-wheels, W. F. Taylor and G. J. Philpott, London.
18,561. Pudding Basin or Mould, J. W. Bray, jun , London.
18,562. Busk Steels and Whale-bones, J. Koehlhofer, London.
18,563. Metal Bedsteads, J. W. Hoyland and W. H. Sturge, Birmingham.
18,564. Gearing Chains, C. J. Chubb and R. H. Seaton. London.
18,565. Levers and Turning-bolts, H. Carmont, London.
18,566. Horse Collar, N. C. Lindsay and H. Stanbridge, London.
18,567. Boxes for Preserving Butter, J. P. Boyd, London.
18,568. Wirework Grating for Stoves, W. L. Clark, London.
18,569. Apparatus for Treating Ores, J. Harris, London.
18,570. Spark Destructors for Engines, F. V. Hawley, London.
18,571. Pasteboard Boxes, P. M. Justice.—(*H Inman, United States* )
18,572. Caps, M. Schneiders, London.
18,573. Printing Machines, C. Pollard and G. Brayshaw, London
18,574. Lubricating Device, A. J. Boult.—(*E. Raikem, Belgium* )
18,575. Gas-fired Boilers, G. H. Taylor and C. B. Waller, London.
18,576. Cycle Driving, H Osborne and J. W. Gaffney, London.
18,577. Making Continuous Hair Felt, J. Newton, London.
18,578. Production of Colouring Matters, H. E. Newton.—(*The Farbenfabriken vormals F. Bayer and Co., Germany* )
18,579. Driving Gear, W. Smith and H. Morriss, London.
18,580. Making-up Hair for General Purposes, S. Lichtenfeld, London.
18,581. Combined Thread Cutter and Thimble, M R. Gray, London.
18,582. Opera Glasses, &c , W. Edwards and G. A. Reid, London.
18,583. Driving Gear for Cycles, &c., S. Smith, London.
18,584. Saddles for Horses, &c , J. W. H. Bleck, London.
18,585. Ball Bearings, E. Fries and W. Höpflingèr, London.
18,586. Ploughs, W. H. Sleep, London.
18,587. Pedals for Cycles, C. Saugster and R. L. Philpot, Coventry.
18,588. New Condensation Products, C. D. Abel.—(*The Actien Gesellschaft für Anilin Fabrikation, Germany.*)
18,589. Colouring Matters, O. Imray.—(*The Society of Chemical Industry in Basle, Switzerland.*)
18,590. Driving Mechanism for Velocipedes, F. V. Mégret, London.
18,591. Cooling and Freezing Machines, T. Hewitt, London.
18,592. Extraction of Precious Metals, H. L. Sulman and F. L. Teed, London.
18,593. Steam Boilers, A. J. Boult.—(*C. W. Baker, United States.*)

*2nd October*, 1894.

18,594. Mouthpieces of Tobacco Pipes, C. H. Smith, London.
18,595. Baskets for Oil Lamps, W. J. Charles, Birmingham.
18,596. Power Transmitting Apparatus, G. J. Altham, Manchester.
18,597. Gulley Traps, R. Greenwood, Manchester.
18,598. Hair Curler, E. Hales and F. G. Hales, Birmingham.
18,599. Fixing Buckles, W. Plowman, London.
18,600. Gripping Material, A. Pulbrook, London.
18,601. Golf Carrier, W. Simpson, Edinburgh.
18,602. Grease Separating Apparatus, W. J. Baker, Scarborough.
18,603. Construction of Oil Lamps, E. J. Shaw, Walsall.
18,604. Show Stands, T. Pearson, Nottingham.
18,605. Match Striker, G. M. G. Partridge, Seacombe, Cheshire.
18,606. Inner Soles of Boots and Shoes, W. Freeman, Leicester.
18,607. Cleansing Foul Casks, O. Tilley, Leicester.
18,608. Mill Furnace, W. Thompson, Gateshead.
18,609. Vehicle Tires, R. Robinson and W. I. Smith, Sheffield.
18,610. Postal Wrapper and Card, W. G. Thompson, Sheffield.
18,611. Looms, G. O. Draper, London.
18,612. Lamps, J. W. White, Widnes.
18,613. Escutcheons, P. C. Jones, Guildford.
18,614. Gas Engine Construction, W. Clark, Newport, Mon.
18,615. Detachable Cycle Handle, H. Waterson, Birmingham.
18,616. Sanitary Drain Trap, G. Francis and S. Rumboll, Leeds.
18,617. Double Eyeglasses, R. A. Rossborough, Glasgow.
18,618. Machine for Washing Gravel, W. Cooper, Dublin.
18,619. Razor Sharpening Apparatus, R. Howarth, Wolverhampton.
18,620. Device for Opening Envelopes, P. Menzies, Glasgow.
18,621. Expansion Driving Clutches, H. Kitson and J. Evans, Bradford.
18,622. Cornice Pole and Curtain Rings, C. Hide, Worthing.
18,623. Bottling and Corking Machines, E. W. Jenkins, Swansea.
18,624. Wagons, J. Roberts and P. Shone and Son, Liverpool.
18,625. Stop Motion for Power Looms, T. Blackhurst, Darwen.
18,626. Cigarettes, S. Bright, London.
18,627. Opening Windows, P. Burt, Glasgow.
18,628. Cycle Brake, E. Cross, London.
18,629. Disinfecting Apparatus, H. Barling and S. Broomhead, London.
18,630. Apparatus for Preparing Fodder, A. F. Davis, London.
18,631. Amalgamator, W. Tarrant, Liverpool.
18,632. Laundry Machine Tapes, A. Conkling and T. S. Wiles, London.
18,633. Bottle Stoppers, J. C. Grout, Liverpool.
18,634. Knitting Machines, G. J. J. Hoffmann.—(*J. A. House, United States.*)
18,635. Flanging, &c , Machine, W. P. Thompson.—(*F. A. Kirby, United States* )
18,636. Fixing Long Handles to Broomheads, G. R. Compton and C. F. Cooper, London.
18,637. Cuff, T. G. Boulton, London.
18,638. Apparatus for use in Brewing, T. R. Todd, London.
18,639. Velocipedes, G. Turner and J. M. H. Venour, London.
18,640. Safety Linen Dryer, C. W. Spong, London.
18,641. Anchors, T. S. Forster, Sunderland.
18,642. Ammunition for Air, &c., Guns, B. R. Banks, Croydon.
18,643. Covers for Pneumatic Tires, H. Paulsen.—(*C. Maret, Germany.*)
18,644. Show Cards, &c., H. Goldenfarb, London.
18,645. Baiting Needles for Worms, B. Blanikmeister, London.
18,646. Game of Billiards, N. Redler, London.
18,647. Hydraulic Thrust Bearing, T. Smalley, Essex.
18,648. Engine Actuated by Explosion, E. M Foot, London.
18,649. Pneumatic Separator for Ores, S. S Allin, London.
18,650. Hydraulic Motors, W. Carter and the Hydraulic Engineering Company, London.
18,651. Binding Pattern-cards, V. Dard, London.
18,652. Grab or Bucket for Dredging Sand, J. Batty, London.
18,653. Manufacture of Oilcloths, C. Hopkinson, London.
18,654. Fastenings for Doors and Windows, A. W. Adams, London.
18,655. Bow Saw, G. Rushbrooke, London.
18,656. Drying and Heating Machines, A. G. Paul, London.
18,657. Heating Apparatus, A. G. Paul and W. P. Skiffington, London.
18,658. Ball Bearings, H. H. Lake —(*A. C. Farnsworth, A. D. Kelley, H. G. Lee, and L. M. Sendelbach, United States* )
18,659. Angle-measuring Instruments, G. A. Rung, London.
18,660. Rims for Wheels of Cycles, W. J. Goddard, London.
18,661. Electric Fuses, The Acme and Immisch Electric Works and E. F. Moy, London.
18,662. Electric Switches, The Acme and Immisch Electric Works and E. F. Moy, London.
18,663. Apparatus for Lighting Buildings, J. S. Roblin, London.
18,664. Heating Systems, A. G. Paul, London.
18,665. Writing Pens, W. Moseley and J. Lewis, London.
18,666. Hanger for Shafting, J. O. Donner, London.
18,667. Type-writers, J. C. Fell.—(*Messrs. Wyckoff, Seamans, and Benedict, United States.*)
18,668. Covering for Earthenware Vessels, W. Gibson, Manchester.
18,669. Potato Harvesters, J. N. Cocker, London.
18,670. Bath-room Soap-dish, H. F. Robinson, London.
18,671. Disinfecting Apparatus, V. B. Lennard, London.
18,672. Door Latches and Locks, J. McLachlan, London.
18,673. Electric Mechanism for Winding Clocks, H. F. Mouquin, London.
18,674. Hollow Rivets, H. Dowler, London.
18,675. Cycle Saddles, H. A. Lamplugh, London.
18,676. Rug Straps, H. A. Lamplugh, London.
18,677. Apparatus for Producing Letters on Bread, R. M. Shaffer, London.
18,678. Manufacture of Curtains, R. C. Wills, London.
18,679. Burning the Vapour of Mineral Oil, S. Pitt. —(*La Compagnie International pour l'Exploitation des procédés Adolphe Seigle, France* )
18,680. Wheels of Cycles, A. C. Lebaupin, London.
18,681. Excluding Dust from Drawers, C. A. Grant, London.
18,682. Fulminating Compounds, H. Maxim, London.
18,683. Process of Nitrating Cellulose, R. C. Schupphaus, London.
18,684. Mud-guard for Cycles, G. G. M. Hardingham, London.
18,685. Binding Cases, H. R. Jones, London.
18,686. Gear-chains for Cycles, J. B. and J. P. Dunlop, jun., London.

*3rd October*, 1894.

18,687. Protectors for Folders, L. B. Phillips, London.
18,688. Automatic Bell for Cycles, T. F. Gunter, London.
18,689. Reversible Hinge, W. M. Tudman and J. Pedley, Birmingham.
18,690. Automatic Grain Weighers, H. Richardson, Lichfield.
18,691. Machinery for Spinning, J. and R. S. Dawson, Bradford.
18,692. Pneumatic Tires, W. A. Rothwell, Manchester.
18,693. Chimney Pot, J. Fielden, Halifax.
18,694. Construction of Wheel, W. Ives, Halifax.
18,695. Advertising Arrangement, S. J. Henochsberg, Liverpool.
18,696. Instantaneous Switches, F. H. Starling, Nottingham.
18,697. Cycles, A. King, Nottingham.
18,698. Gear Cases for Cycles, S. A. Newman, Birmingham.
18,699. Sack-hoist for Thrashing-machines, F. J. Burrell and T. Hibberd, jun., Thetford.
18,700. Door Springs, W. A. Gill and P. E. Ayton, Birmingham.
18,701. Combination School Desks and Seats, A. Bruce, Dundee.
18,702. Pneumatic Razor Strap, C. A. Moon and J. McCullagh, Dublin.
18,703. Mantelboard, A. Travis, Burnley.
18,704. Steam Generators, E. P. Plenty, jun., and J. W. Davis, London.
18,705. Dredger Rake, J. Hansard, Llanelly.
18,706. Safety Valve for Boilers, J. and H. Parker, Bradford.
18,707. Securing Cycle Pedals, W. H. Toussaint and W. E. Ginder, Birmingham.
18,708. Making Iced Drinks, H. W., S. M., and P. Chinnery, Walthamstow.
18,709. Axes, W. Smith, Birmingham.
18,710. Non-slipping Boot Protector, W. C. Phillips, Bradford.
18,711. Creating Draughts for Fires, R. C. Sayer, Bristol.
18,712. Casks, A. J. Twyford, London.
18,713. Whist Marker, C. J. Dury and W. B. Marchington, London.
18,714. Treadles for Railway Signals, J. G. Dixon, London.
18,715. Fuel-saving Compound, A. W. Summers, Bristol.
18,716. Pipe Barrow, R. Malabar, Liverpool.
18,717. Taps, S. Plumbly, Leicester.

18,756. Detachable Outer Cover for Tires, W. Moss, Manchester.
18,757. Insulators, W. Parrott, A. Essinger, and T. Harden, London.
18,758. Water-tight Joints, H. H. Lake.—(*F Krupp, Grusonwerk, Germany.*)
18,759. Solitaire and Shear Sharpener, W. S. Freeman, London.
18,760. Cover for Boilers and Furnaces, A. E. Adams, London.
18,761. Fastening for Miners' Lamps, L. Lhoneux, London.
18,762. Toilet Mirrors, A. F. White, London.
18,763. Mudguard for Trousers, R. Raffety, London.
18,764. Cocks, H. L. Doulton, London.
18,765. Purifying Sewage, W. E. Adeney and W. K. Parry, London.
18,766. Attaching Fasteners to Clothes, E. G. Fuller, London.
18,767. Switches, D. Bates, T. Harden, and O. L. Peard, London.

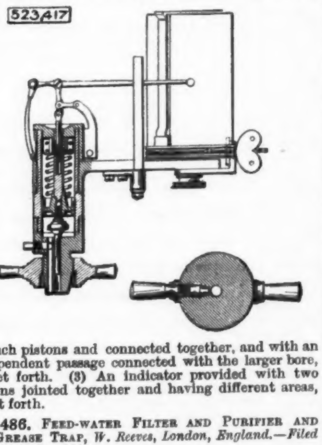
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**523,417.** Steam Engine Indicator, *H. A. Spiller, Boston, Mass.—Filed November 4th*, 1892.

*Claim.*—(1) An indicator provided with two pistons having different areas, as set forth. (2) An indicator provided with two pistons connected together and having different areas, with a cylinder having bores to fit such pistons and connected together, and with an independent passage connected with the larger bore, as set forth. (3) An indicator provided with two pistons jointed together and having different areas, as set forth.

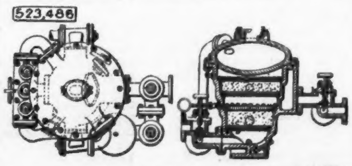
523,417



**523,486.** Feed-water Filter and Purifier and Grease Trap, *W. Reeves, London, England.—Filed March* 1st, 1894.

*Claim.*—(1) In a filter, the combination of a filter chamber a reservoir for receiving new charges of filtering material, a charging door for said reservoir, a communicating thoroughfare between said filter chamber and reservoir, and another thoroughfare independent of the filter chamber between the reservoir and the inlet pipe of the filter, substantially as described for the purpose specified. (2) In a filter, the combination of a filter chamber having its influx and efflux sides formed by strong grids covered on that side which faces the flow of the liquid with gauze or the like of fine mesh and filled with absorbent filtering material, a reservoir for receiving new charges of filtering material, a charging door for said reservoir, a communicating thoroughfare between said filter chamber and reservoir, another thoroughfare independent of the filter chamber between the reservoir and the inlet pipe of the filter, a chamber containing a layer of zinc balls situated below said filter chamber, a by-pass communicating with the inlet and outlet pipes of the filter, and a filter chamber in said by-pass, substantially as described and for the purpose specified.

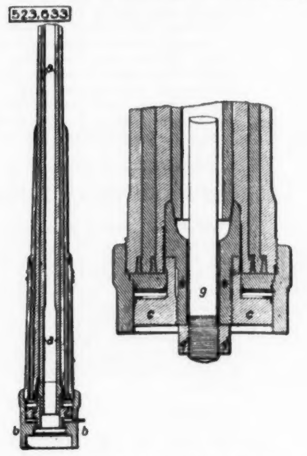
523,486



**523,633.** Device for Inserting or Removing Tubes in Ordnance, *M. Gledhill, Manchester, England.—Filed July 21st*, 1892.

*Claim.*—(1) The combination, with a built-up gun, of a hydraulic apparatus comprising a cylinder *b* screwed on the breech end of the outer tube or hoop of the gun, a piston *c* working in said cylinder, a socket *e* secured to the said piston and to the breech end of the liner, and a withdrawing rod *g* engaging the piston *c* at its rear end and the liner at its forward end, substantially as described. (2) The combination with a built-up gun, of a hydraulic apparatus comprising a two-chambered cylinder *b* screwed on the breech end of the outer tube or hoop of the gun, a piston *c* working in one of said chambers, a socket *e* for coupling said piston *c* with the rear end of the liner *a*, a piston $c^2$ working in the other of said chambers, and a rod *g* extending through the bore of the gun, said rod having a head *g'* at its forward end engaging the muzzle end of the liner and a liner $g^2$ at its rear end for connecting the rod with the piston $c^2$, substantially as described for the purpose specified.

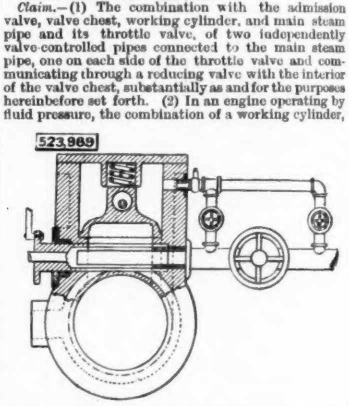
523,633



**523,969.** Balanced Valve, *J. A Bourgeat, New York, N.Y.—Filed October 29th*, 1890.

*Claim.*—(1) The combination with the admission valve, valve chest, working cylinder, and main steam pipe and its throttle valve, of two independently valve-controlled pipes connected to the main steam pipe, one on each side of the throttle valve and communicating through a reducing valve with the interior of the valve chest, substantially as and for the purposes hereinbefore set forth. (2) In an engine operating by fluid pressure, the combination of a working cylinder, an admission valve, a pressure chest surrounding and covering the admission valve, a throttle valve, two pipes, one on each side of the throttle valve and connected to the main pressure inlet pipe, in each of which pipes is located a hand valve, said pipes being joined together beyond said valves, and a reducing valve, through which the pipe joining the two pipes before mentioned passes into the pressure chest, substantially as described.

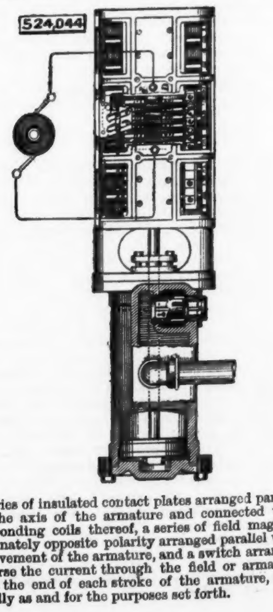
523,969



**524,044.** Electric Pump, *F. W. Merritt and A. R. Roe, Duluth, Minn.—Filed November 6th*, 1893.

*Claim.*—The combination of a pump cylinder provided with a reciprocating piston, a bar armature attached directly to the piston-rod and provided in the direction of its length with a number of coils, a commutator carried by said armature and consisting of a series of insulated contact plates arranged parallel with the axis of the armature and connected with corresponding coils thereof, a series of field magnets of alternately opposite polarity arranged parallel with the movement of the armature, and a switch arranged to reverse the current through the field or armature coils at the end of each stroke of the armature, substantially as and for the purposes set forth.

524,044



## THE ENLARGEMENT OF LIVERPOOL STREET STATION, GREAT EASTERN RAILWAY.

### No. V.

*Double and single stanchions.*—The arrangement of double columns carrying single vertical stanchions, shown in Fig. 23, is continued throughout the whole length of the Parcels Office until the end walls are reached, when a modification of the former design is adopted. Restricting our attention for the present to the far, or railway end wall of the office, where the fantail gallery and approach from the first part of the terminus joins on to the building, we find that at the junction the double cast iron columns are replaced by twin stanchions, and an upper single one of the same material ranged in both the first and second storeys flat against the wall, something after the manner of a pilaster, or considering the depth of the projection, more like an interior counterfort or buttress. An elevation of these double stanchions, and supports for the first and second floor, is shown in Fig. 23, together with cross sections of the longitudinal plate girders, which will be subsequently referred to. While the general disposition of the various parts is similar to that already described for the twin columns, and includes a table girder, it is to be noticed that the cast iron bed or base-plate is in three parts, and consists of an upper wedge-shaped polyribbed girder, 4ft. deep at the centre, 2ft. 6in. deep at the ends for a length of 3ft. over the bearing plates, and 3ft. in width, as shown in Figs. 23—25. In the last figure it is seen in cross section through D D in Fig. 23, and is practically of almost the same dimensions and form as the table girder, surmounting the twin columns with a trough lower flange 3½in. thick in the horizontal part, and 3in. in the vertical sides, tapering to 2½in. at the upper end. Both the middle rib and the upper flange are 3in. in thickness, diminished in the flange to 2½in. at the horizontal edges. This upper bed-plate is supported by two others, that is, it virtually rests upon a pair of hollow cast iron abutments which stand upon a solid foundation of concrete, as represented in Figs. 23, 24, and 26, and is thus in the position of a girder with a clear span of 11ft. 4in. Each of the under bed-plates consists of a hollow casting measuring over all 8ft. by 6ft. 8in. It has a depth of 1ft. 6in., with flanges 3in. thick, a vertical rib, and sloping faces 2½in. in thickness, and is secured to the concrete by six slotted wedges or bolts. Upon the upper bed-plate or girder, as it virtually is, are bolted the double stanchions shown in elevation in Fig. 23 and in section in Figs. 24 and 28, where they have the appearance of a very large channel iron 2ft. by 1ft. 10½in. by 1½in. thick, and provided with a central rib of one-half the depth of the sides. They are bolted down to the base girder by a pair of bolts 1⅜in. in diameter. To the capitals of the double stanchions is bolted the table girder, Figs. 23 and 26, which is a polyribbed double flanged horizontal cast iron girder, 7ft. long, 3ft. deep, 2ft. 6in. wide, 3in. thick at junction of flanges and web, 2½in. at edges and in the web, and is shown in section at C C in Fig. 26, which also contains an elevation of the single stanchion shown in section in Fig. 27. It is of the same form and of the same dimension in elevation as the pair which support it; but, instead of being 1ft. 10½in. in cross section, it is reduced to 1ft. 4in., and is ⅛in. less in the different thicknesses. It will be evident that where the double columns and single vertical stanchions are placed at right angles to the side walls of the building, some alteration must be made in the relative position of the different members of the supports. It is no longer possible to carry the load or adjust the centres of the box girders in a line with the vertical axis of the columns, so that the *ensemble* of the especial arrangement is represented in Fig. 29, and a section through the centre of the table girder in Fig. 30. The proportions, thicknesses of metal, and general sections are similar to those already described and illustrated.

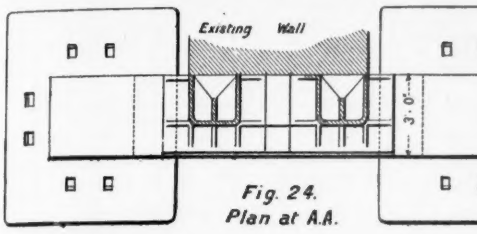


Fig. 24.
Plan at A.A.

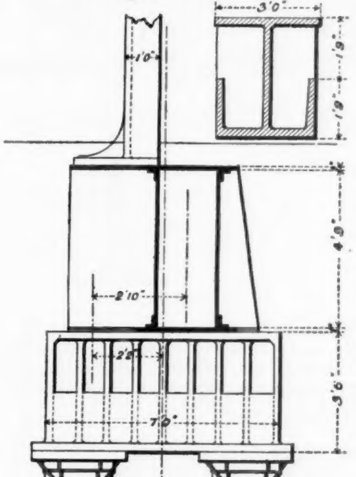

Fig. 29. Fig. 30.

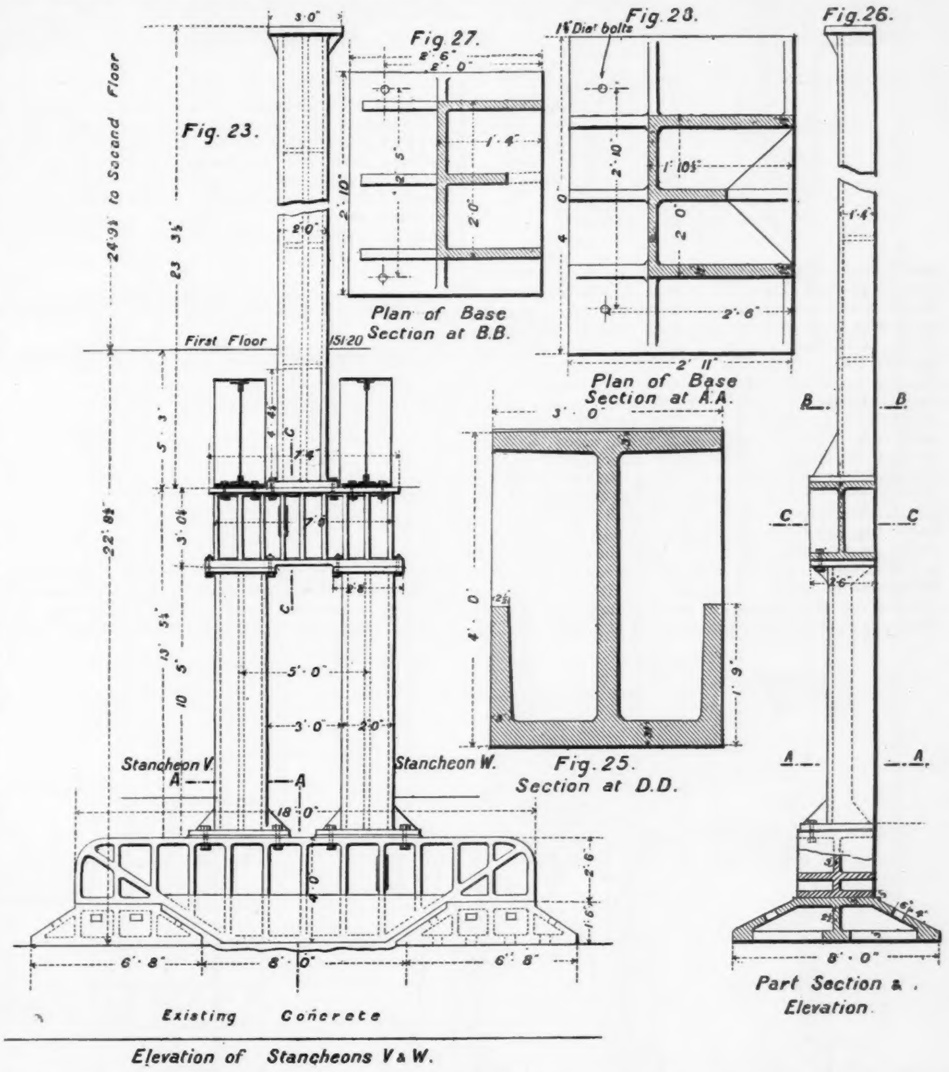
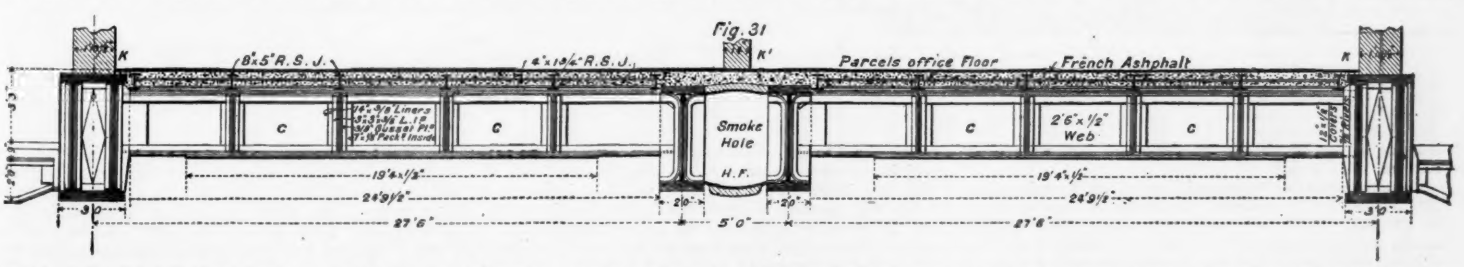
*Box girders.*—An enlarged cross section at floor level of the two central spans of the Parcels Office is given in Fig. 31. It is taken through the line of the tracks, and contains details of the construction which are not shown in the former figures. Each side wall K of the building is carried upon a box girder of great strength, of which the sections at the centre and ends respectively are seen in Figs. 32 and 33. At the centre the girder is 5ft. 7in. in depth over all, which dimensions includes a cover-plate ½in. thick in both the upper and lower booms. These cover-plates are each 14ft. in length, and designed so as to cover collectively the separate joints in the different plates, and thus avoid the multiplication of individual wrappers and cover plates of shorter proportions. There are nine plates, 3ft. in width, which quantity is constant throughout the entire length of the girder, which is 51ft. 11½in., and all ½in. in thickness at the centre, diminishing to two plates of the same thickness at the ends over the columns as in Fig. 33, which also shows a portion of the stanchion of the table girder over the twin columns. Of the ½in. flange plates the maximum length is 30ft., which gives rather more than a quarter of a ton for the weight of a single plate. What may be regarded as the common or constant part of the section of the box girder consists, therefore, of two plates 3ft. by ½in. each flange, of four angle irons 4in. by 4in. by ½in., of a maximum length of 34ft. 5in., and a pair of sides or webs placed 2ft. apart from out to out, and varying in thickness from ½in. at the centre to ⅞in. at the ends. In the flanges, the rivets passing through the plates and angle irons, are 1in. in diameter, but only ⅞in. elsewhere, unless otherwise specified. All bearing surfaces are flush riveted, and the rivets are pitched 4in. from centres. At distances of 10ft. 8in., where the transverse floor girders are placed, the webs of the main longitudinal box girders are stiffened by double angle irons 3½in., by 3½in. by ½in. Figs. 32 and 33.

*Plate girders.*—Dividing for a portion of the height the two spans of the Parcels Office, is a partition wall K, shown in Fig. 31, and 14in. in thickness. Here the longitudinal box girders carrying the side walls are represented by a pair of plate girders whose vertical axes are in a line with those of the twin columns, supporting the table girder upon which they rest. Each plate girder—Fig. 34—is 4ft. 6in. deep at centre, has flanges composed of six plates ½in. in thickness and 2ft. wide, diminishing to one at the ends. Angle irons 4in. by 4in. by ½in. rivet the horizontal flange plates to the web, which has a varying thickness from ½in. at centre to ⅝in. at the ends. An exception to this otherwise uniform width of flanges occurs on the inner side of the girders or those facing each other. The plates—Figs. 31 and 36—next the angle irons in both flanges are 2ft. 3in. in total width, the additional projecting 3in. serving to carry the cast iron flue plates of the smoke chamber, which will be subsequently alluded to. Passing on to the transverse floor girders C C—Fig. 31—they are also of the plate description, as shown in cross-section in Fig. 35, where they are riveted at their junction with the main longitudinal plate girders.



Elevation of Stancheons V & W.

Part Section & Elevation.



*Floor girders and joists.*—The general arrangement of the floor of the Parcels Office will be apparent from an inspection of the two Figs. 31 and 36. Upon the cross girders C are riveted at intervals of 5ft. apart the rolled steel joists F F, which have a depth from out to out of 8in., a width over both flanges of 5in., and a weight of 31·25 lb. per foot run. To the lower flanges of these are attached smaller rolled steel joists, spaced 1ft. 6in. apart, and having a section of 4in. by 1¾in., and a weight per running foot of 8·5 lb. Between and around this skeleton steel gridiron flooring framework is well rammed and thoroughly consolidated a mass of concrete composed of coke breeze and Portland cement in proportions of about 5 of the former to 1 of the latter. It will be seen in Fig. 36 that there is a depth of 2in. of this concrete over the larger sized rolled steel joists, and a depth of 3in. below them, forming a kind of ceiling to the under storey. While in process of ramming and consolidation the lower surface of the concrete was supported by temporary sheeting boards and props. Over the concrete is spread a layer of French asphalt 1in. in thickness, A different description of flooring is adopted for the side approaches to the Parcels Office, as will be seen on referring to the details in Figs. 37 and 38. The smaller rolled steel joists are dispensed with, and their place occupied by cast iron plates. These latter vary slightly in their dimensions, which are on an average 4ft. 8in. by 4ft. 3in. They have a dip of 2½in. and a uniform thickness of ⅝in. metal. The plates are in two lengths, Fig. 39, and are bolted together by three bolts ⅝in. in diameter. A section of the joint is given in Fig. 40. Over the cast iron plates is laid a bed of concrete, and upon it are bedded wood blocks 5in. in depth. A similar description of flooring obtains for the ramps or inclined approaches from Bishopsgate-street, but the rolled steel joists are a little heavier in section, being 9in. deep and 7in. wide over flanges.

Fig. 32

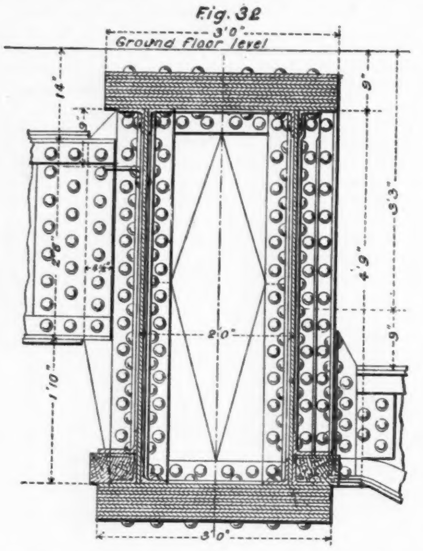


Fig. 33

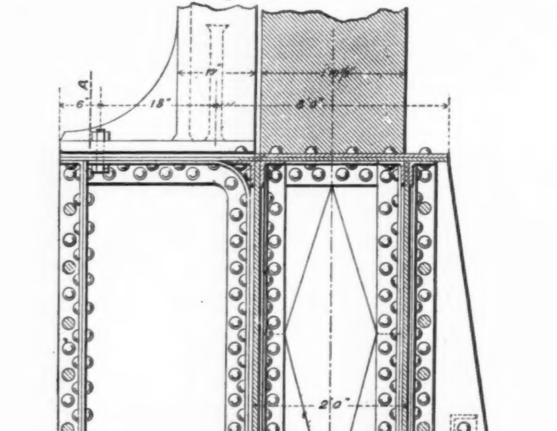

*Smoke flue.*—In the general plan of the Parcels Office the letters T T T indicate the lines of track—eight in number, which all pass underneath the building at the entrance to the station, and as at certain times the engines are passing, and also standing beneath the same spot, it becomes necessary to make some provision for carrying off the smoke, waste steam, and other gaseous vapours emitted by locomotives, which we shall now proceed to describe. It must be premised that a horizontal flue, H, F—in Fig. 31—is carried the whole length of the Parcels Office, between the double longitudinal plate girders, and is built of side walls of brick, with top and bottom curved cast iron plates. This flue or smoke-hole is connected with four smoke stacks S, which are continued right up through the building to a height of about 4ft. above the ridge of the roof. In case the draught should not be sufficient to keep the station and the area below the building clear of smoke, fans can be used; but hitherto there has been no necessity for their employment. Each stack has an opening in the clear of 2ft. 3in. by 2ft., and consist of a series of cast iron plates bolted together through external flanges. Between each pair of tracks, at or near the point where the locomotives would stand underneath the Parcels Office, is constructed a smoke chamber, shown in detail in Fig. 41. There are consequently four altogether, shown in section to a larger scale with the main longitudinal girders M, the cross girders C, and the rolled steel joists V and $V_1$, Fig. 41. Each smoke chamber is therefore built parallel to the main longitudinal plate girders of the Parcels Office, and occupies a space equal to the distance 10ft. 8in. between the pair of adjoining cross girders C C. Along the steel joists V, which are 14in. deep by 6in. in width, at intervals of 1ft. 2in. are rivetted tee irons 4in. by 3in. by ½in. Concrete temporarily supported as before mentioned, is rammed all round, so as to form the floor of the chamber and one wall of the smoke passages P P, in Fig. 41. The other side wall consists also of a bed of concrete 14in. deep, which connects the cross girders C C with the rolled steel joists V, having a section of 12in. by 6in. The passages P P are open to the air, and through them passes the smoke and steam of the locomotives into the chamber. From hence they find their way over the top of the main girders M into the smoke-hole, Figs. 36 and 41, from which they gain access to the horizontal flue, and finally reach the open by means of the respective smoke stacks.

Fig. 34

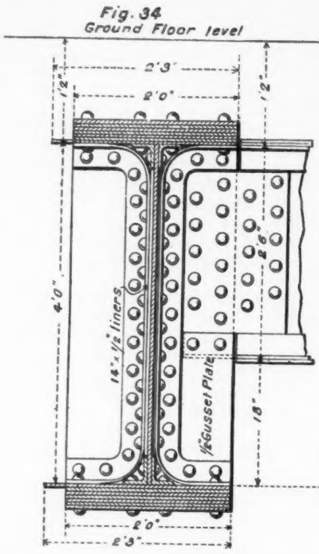

Fig. 35

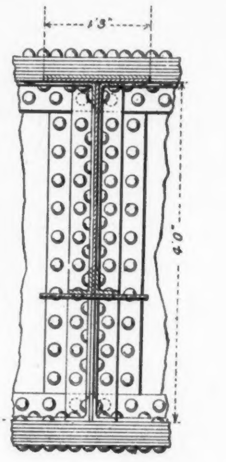

*Second storey.*—Although it is possible that the second storey of the Parcels Office may not be subjected to loads of quite the same weight as that immediately below it, yet it is constructed in a similarly strong and substantial manner, which will appear on inspecting the general cross section and Figs. 1A—6A. The first of the last three figures is a cross section to an enlarged scale of one-half, or one span, of the girders and ceiling of the first storey of the building. To the top of the central stanchion is bolted a box girder P, the details of the construction of which are very similar to those already described and illustrated, for the girders carrying the flooring of the office. The girder P, a portion of which is shown in elevation and plan in Fig. 4A, has a depth of 6ft., a width over flanges of 3ft., and two webs ½in. thickness each. All the flange plates, the longest of which is 30ft., which vary from two to seven in number, are ½in. thick, and are riveted to the webs by rivets 1in. in diameter through the horizontal angle irons, 4½in. by 4½in. by ⅝in. Rivets in other parts of the girder are ⅞in. in diameter, with a pitch of 4in. Plate girders W, supported like the box girder P by cast iron stanchions, carry the cross-girders $P_1$ at the side walls. They have the same depth of 6ft., but are only 1ft. 8in. in width, while the thickness of flange plates, angle irons, and web is ½in. throughout, but the sides of the angle irons are reduced to 4in. by 4in. The junction of the girders W and the cross girder $P_1$ is shown in Fig. 6A, and needs no further description. An elevation of the cross girders $P_1$ and a section of them are given in Figs. 1A, 2A, and 3A. They are spaced, as a rule, 21ft. 2in. apart, although this distance varies in

Fig 6A

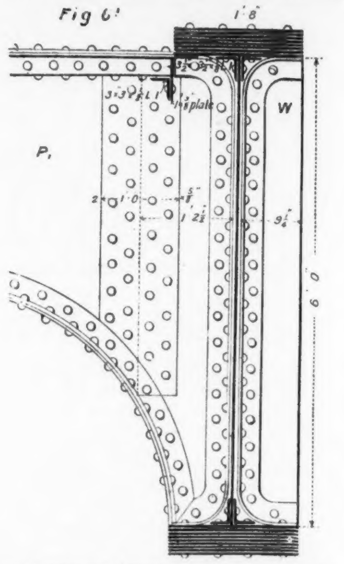

Fig. 36.

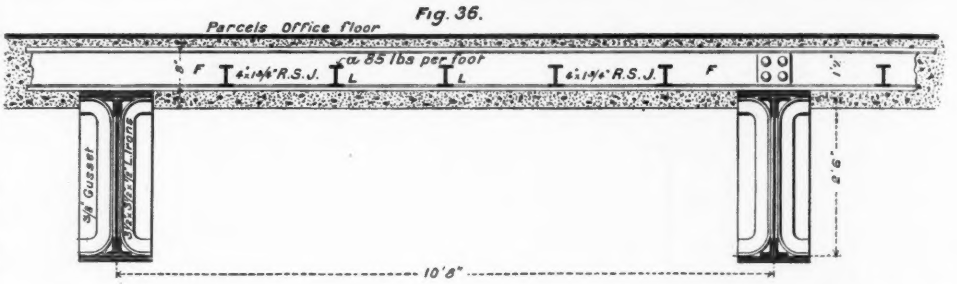

Fig 37

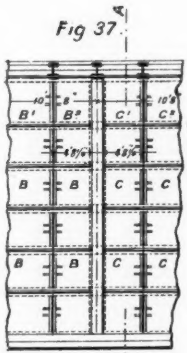

Fig. 40.

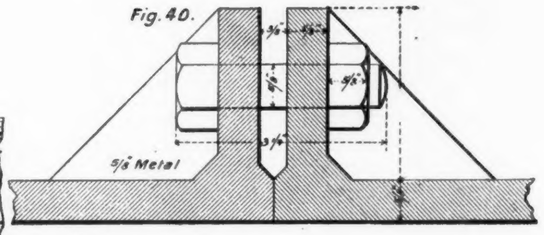

Fig. 38.

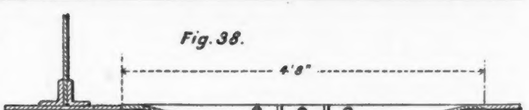

Fig. 39.

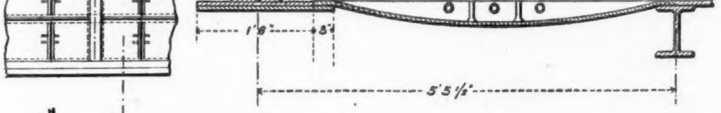

some of the bays, are 3ft. 6in. deep at centre and 2ft. in uniform width. These distances correspond with the spans of the smaller plate girders $P_2$, which carry the ceiling joists of timber 5½in. by 4in. To these are bolted the runners 3½in. by 2¼in., to which the sheathing and layer of expanded metal and plaster are attached, as shown by the strong dark line in Figs. 1A and 2A. Upon the upper storey are situated the offices appropriated to the use of the officials and employés of the company, the whole back and front ranges being divided by a corridor running the entire length of the handsome façade erected along the north side of Bishopsgate-street.

The whole of the heavy ironwork in connection with the new building was constructed and erected by the well-known firm, Messrs. Head, Wrightson, and Co., of the Teesdale Ironworks, Thornaby-on-Tees, and of 5, Victoria-street, Westminster. We are indebted to the courtesy of Mr. S. Young, of the firm, for some particulars respecting the work. In the columns, stanchions, and floor plates there were some 620 tons of cast iron used, and the box and plate girders and their accessories accounted for 1230 tons of wrought iron. The heaviest box girders weighed as much as 40 tons, and 100 tons were taken up by the footbridge. They were riveted up complete by machine riveting in the workshops, sent by special train to their destination, and hauled up bodily to their permanent site by a couple of powerful derricks. Some riveting was done necessarily on the premises, all by hand. About 130 tons of steel floor joists were fixed in position. The whole of the materials and workmanship was English, and the contract occupied about sixteen months, the work being carried out from beginning to end without a hitch or accident of any kind whatever. The six hydraulic lifts were provided from the Elswick Works.

## THE VICTORIA BRIDGE OVER THE BRISBANE RIVER.

By the two-page supplemental engraving which we publish this week, we commence the illustration of the new Victoria Bridge now being erected over the Brisbane River, from the designs of Mr. Alfred R. Brady, Assoc. M. Inst C.E. After the destruction of Victoria Bridge by the great flood of February, 1893, a sketch design for a bridge was prepared by Mr. Alfred B. Brady, who is Engineer for Bridges to the Department of Public Works, and received the approval of the Government, and also the warm commendation of Mr. John Whitton, M.I.C.E., for many years engineer-in-chief of the New South Wales Railways, who at the request of the Premier—the proposed bridge being an engineering work of much magnitude—went carefully over the design, and spent some time in examining the site and the old bridge. The preparation of the working plans was then proceeded with. Of a selection of these we now commence the publication. Invitations for tenders were issued, and a large number received by the 28th March last. The selected tender was accepted on the 10th of April last, the contract time being thirty months for completion.

The bridge will consist of six 170ft. spans, with three main longitudinal girders in each span, the whole carried upon five piers of three cylinders each. The girders will be of the hog-backed-lattice type, 22ft. deep at the centre and 10ft. at the ends, and constructed of mild steel. The cylinders will be of cast iron, and the bridge will have abutments of masonry, backed with concrete. For about half the length of each span the main girders will be braced overhead with light lattice girders and diagonal bars. One end of each main girder will be fixed on cast steel rocker bearings, but the other end will rest on expansion rollers of cast steel, and of an improved interlocking pattern. The bearings of the main girders on the abutments will rest on massive granite bed-blocks.

The length of the bridge between the faces of the abutments will be 1011ft. 8in., while the width between the parapets of the footways will be 73ft. The level of the roadway above high-water mark will equal 36½ft. at the north end and 25ft. at the south end of the structure, the gradient thus being 1ft. in 90ft. The level of the highest known flood in the Brisbane River, 27·17ft. above high water ordinary spring tides, was recorded on February 5th of this year. In the event, therefore, of a repetition of that disastrous inundation there would be only about 2ft. of slack water on the roadway at the southern approach to the bridge, whilst at the north end of the bridge, where the current was strongest, the roadway would be 9½ft. above the highest flood level. The surface of the roadway on the new structure will be 2ft. higher than the old throughout its length, affording a clear height or headroom above water level of 3ft. more than existed under the superstructure of the old bridge. The weight of the iron and steel work in the new bridge will be about 3265 tons, of which about 1860 tons will represent the weight of steel.

*Cylinder piers.*—Every cylinder, three of which form a pier, will be sunk to a hard rock foundation, each pier in the direction of the stream having a base of 63ft. Judging from borings made after the February floods, the depth to which it will be necessary to sink the cylinders will vary from 60ft. to 90ft. below high-water mark. The diameter of the cylinders from the foundation to some distance above the level of the river bed will be 10ft. At that level the diameter will be reduced to 8ft. by a tapering cylinder, and again at high-water mark a strong moulded base casting on the cylinder will reduce the diameter to 6ft. From the moulded base to the cap the cylinders will be 6ft. in diameter. The outer cylinders will be $1\frac{3}{8}$in. metal at the base, reduced to $1\frac{1}{8}$in. metal above high-water mark. The centre cylinders will be of $\frac{1}{8}$in. thicker metal throughout, in order to sustain the extra weight thrown upon the centre girders. The cylinders will be filled to the top with Portland cement concrete, and finished with ornamental cast iron caps and bases in keeping with the architectural treatment of the stone abutments and arches to same. Wrought iron riveted diaphragm bracing of great strength will connect the cylinders, each pier having four elliptical panels above high-water level, with girder ties at top and bottom. The web-plates will be pierced with ornamental design. The cylinders will be further braced with heavy cast iron spandrils firmly bolted to them below high-water level. In fact, the whole of the bracing, apart from the greatly increased dimensions of the piers, is calculated to give a strength that was entirely wanting in the light diagonal bar-bracing of the old bridge piers.

*Masonry abutments.*—The bridge will gain considerably in beauty and finish by having massive and architecturally treated masonry abutments and arches over the footways at each end. The abutments will be faced with O'Connelltown purple hard stone, rock-faced with margin drafts and V joints, and surmounted by heavy moulded and bracketed cornices of brown freestone. There will be solid piers and archways, the latter of a clear width of 9ft. to each footway, and lamp pillars, built in white and brown stonework, to cover the ends of the centre girder. For the wing walls a quadrant form has been adopted. The walls will run outwards from the archway piers, and terminate with square lamp pillars. The wing walls will be entirely of brown freestone, with heavy moulded copings. The lamp pillars and piers to archways will have alternating bands of brown and white stone upon O'Connelltown-stone plinths, with rusticated joints and moulded bases, copings, and seats for lamps, and moulded imposts under the arches. The arches and the piers at the arch level will be entirely of white freestone, with rusticated joints and moulded panels in the soffits and piers, the latter filled with slabs of polished ornamental granite. Surmounting these will be an entablature treated in the Doric style, enriched with details and triglyphs, and heavy splayed blocking on top. The abutment at the north end will be founded on rock, while the southern abutment will be carried upon a foundation of driven piles.

*Roadways and footways.*—There will be two road or carriage ways and two footways. The centre girder will divide the roadways, which are each to be of a clear width of 24ft. Cantilevers springing from the outer main girders will carry the footways, each 9ft. wide in the clear. The decking of the bridge will be constructed of steel trough plates 12in. deep, laid transversely between the main girders and riveted to the flanges of the same. This decking will be covered with tarred blue metal, finished on the surface with a layer of mineral asphalt $\frac{3}{8}$in. thick, on which a pavement of hardwood blocks 6in. deep, with $\frac{3}{8}$in. asphalt joints, will form the carriage-ways. It is intended that vehicles and animals approaching the north side of the river shall use one roadway, and those leaving the city the other, a similar arrangement being made with regard to foot passengers on the footways. The flooring of the footways will consist of corrugated steel plates laid longitudinally, riveted to the cantilevers, levelled with tarred blue metal screenings, and the surface covered with Val de Travers or Seyssel's asphalt 1in. thick. The parapets of the footways will be of wrought iron lattice work with a moulded hardwood handrail, and ornamental wrought iron brackets on the ends of the cantilevers, the brackets being finished at the top with ornamental cast iron finials.

*Approaches.*—The increased width of the bridge will require a corresponding increase in the width of the approaches. On the north side the lamp pillar at the corner of the Queen's-road and William-street will be moved back a distance of 18ft. That much of the retaining wall will be taken down and the necessary levelling done to give a better approach from William-street. At the South Brisbane approach the shops on the west side of Melbourne-street will not be affected save by the slightly-raised level of the approach roadway, but the building on the east side, known as the People's Cash Store, will have to be removed. The land on which the store is built, together with the right-of-way alongside, will be acquired by the Government and thrown into the approach, making a total width of 132ft. On the north side the tram lines will take an easterly sweep on to the bridge.

*Fender piles.*—For the purpose of protecting the bridge against contact with floating *débris* during flood time, fenders will be provided opposite each pier on the upstream side. Each fender will be of Λ shape, and will consist of five piles driven to a hard foundation, and being of the height reached by the 1893 flood, and sheathed with muntz metal up to high-water mark. The piles will be strongly braced together, and sheathed on the outside, above high-water mark, with 9in. by 3in. hardwood planking. The nosing of the fenders will be protected with $\frac{1}{2}$in. wrought iron plates, 2ft. 6in. in breadth. The width of the fenders across stream will be 10ft., and their length in the direction of the stream 20ft. In order to reduce the contraction of the waterway to a minimum, the fenders are to be placed in crescent form, the clear space between them and the bridge varying from 28ft. to 68ft.

*Lighting of the bridge.*—Gas fittings are to be provided for the lighting of the bridge, but if it should at any time be decided to employ the more modern illuminant, they will be suitable for carrying electric lights. The lamps to be used will vary from 20 to 50-candle power. The approaches will be lit by a four-light lamp on each pillar, carried upon ornamental cast iron standards, and on each side of the archways there will be two lanterns fixed to the walls with ornamental wrought iron brackets. At each intersection of the outer girders, over the piers, there will be three-light lamps on ornamental cast iron standards for the lighting of the roadways and footways. In addition, in the centre of each span in each roadway will be suspended a 50-candle power lamp, attached to the overhead lateral bracing by means of an ornamental bracket. Gas will be supplied to the lamps by service pipes from the companies' mains, half the supply being drawn from the city side and half from the south side of the river.

*Water pipes, tram lines, and telegraph and telephone cables.*—Provision is made to carry water across the bridge by means of two riveted steel 12in. pipes suspended beneath the decking on each side of the centre girder. The Brisbane Board of Waterworks will supply the pipes, which for the sake of convenience will be placed in position by the contractor for the bridge. In the same way the contractor will put down the tram lines, the Metropolitan Tramway Company providing rails and all other necessary material. The tram lines will be laid in each roadway alongside the centre girder. The cost incurred under these heads by the Bridge Board will be refunded by the board of waterworks and the tramway company. Close to the parapets and below the surface of the footways will be wooden troughs, in which the electric telegraph and telephone cables will be laid. The unsightly overhead system of telegraph wires will thus be done away with so far as the bridge is concerned.

*Building.*—The bridge is being built in two sections. Two of the three cylinders required for each pier will be sunk on the east or down-stream side of the existing bridge. This will carry one-half of the new structure, and by fixing two of the girders of each span in position and laying down the flooring, a roadway and a footway will be ready for traffic. The completed half may then be availed of by the public, the remaining old bridge and the temporary structure removed, and the remaining or up-stream half of the new structure erected. The centre line of the new bridge is only 32ft. down stream from the centre line of the old one. The parapet of the up-stream footway of the new bridge will be 18ft. removed in a down-stream direction from the up-stream parapet of the old bridge. Although the work is to be completed in two and a-half years, it is expected that the first section of the bridge will be ready for traffic in twenty-one months from the date of the contract.

## COFFEE AND CACAO DRYING MACHINERY.

The preparation for market of many items of tropical agricultural production differs materially in several important respects. Those the harvesting of which is in the leaf may usually be subjected without injury to rapid and intense heat, while such as are of the character of beans need to have their moisture expelled far more gradually. Partaking of the nature of these last are the fruits of the coffee and cacao trees, from the second of which the ordinary so-called cocoa of commerce is prepared. Not alone does the difference in the required treatment to which we have above referred exist, but the method of applying it varies in the different countries producing the same plants. Both coffee and cacao, for instance, grow freely in Ceylon, but it is exceptional in respect to that island to have to resort to artificial heat for their preparation. Sun heat in the eastern colony is only interrupted by rain at comparatively regular intervals, and the beans of both the plants named can be safely given the exposure to it necessary to efficiently dry them. Irregular rainfall, however, deprives other countries of this advantage. Notably is this deprivation felt in some of the provinces of South America, wherein the cultivation of coffee and cacao is widely carried on. None of these provinces, perhaps, suffer more seriously from this irregularity than does that of Ecuador, and it is a machine designed by a planter of that province that we were recently afforded an opportunity of seeing in action. Its object, as may be inferred from the foregoing remarks, is to cure the beans, both of coffee and cocoa, by artificial heat, so as to avoid the risk of damage during the drying process which would arise from unanticipated rainfall.

The machine illustrated is one of six that have been constructed in this country for shipment to Ecuador by Messrs. Bowes, Scott, and Western, of the Phœnix Wharf Works, Battersea, upon the design of Mr. Juan Gamarra. Its total length is 60ft., and its width 7ft. In its main feature it is a box of these dimensions, built of light iron plates fastened on a framework of either wood or iron. This box is without any internal divisions throughout. Over the drums A A, and given motion to by them, passes an endless band B B B B of woven copper wire of the full width of the containing box or casing. The band is supported at frequent intervals upon transverse rollers C C, while its edges pass along grooved slides extending for its whole length. These slides serve to keep the beans from falling off the band. Below this last a system of hot-water pipes D D is provided. The beans are fed on to the band while in motion through the transverse hopper E, which has its lower orifice so arranged as to ensure delivery of a uniform thickness of charge—usually some 2in. to $2\frac{1}{2}$in.—upon it. The band carrying this layer of beans moves forward in the direction shown by the arrows. During its passage the beans are kept stirred by the stirrers F F, there being six of these throughout the length of the machine. A slow circular motion is imparted to these by the worm gearings at G G G, driven by the shafting H H. The prongs upon the radial arms I I are so disposed throughout the system as to ensure that the whole mass of beans should be repeatedly turned over during its travel to the point of its discharge at K, and so permit the free permeation throughout it of the heat from the pipes, ensuring uniformity in the drying. One of the drums over which the band passes is driven at very slow speed by the screw and pinion gear at L upon the main driving shaft M, the power being transferred to the drum by similar gearing at N. On the intermediate shaft is provided a coupling, whereby it may be disengaged from the main driving shaft and the machine actuated by a handle worked by manual power. A circular fan is provided at O to withdraw the damp heated air arising from the beans during the process of drying.

As has been above remarked, the motion given to the carrying band is extremely slow. It is computed that four hours should be occupied by the beans to be dried from the time of their falling on the band from the hopper E to that of their delivery at the other end of the machine. This time is calculated as sufficient exposure to the heat of the hot-water pipes to thoroughly dry them. It is approximately estimated that each machine can so prepare two tons of beans per day, so that the output of the whole battery of six machines, equal to 12 tons daily, would suffice for the production of a very large estate indeed. The inventor prefers the use of hot-water pipes to that of heated air for a very sufficient reason; this being that having to trust largely to unskilled labour, less risk is run of excessive heating by this method than might result from the employment of that second-named. The power required to drive this seemingly heavy piece of machinery is singularly small. On trial we found this to certainly not exceed half a horse-power, and it was manifest that manual labour could be readily availed of if necessary. We believe it to be Mr. Gamarra's intention to work the whole battery of six machines in line, motion to be given to the driving shafts when coupled up by a mule whim.

From what we heard, these machines are, relatively to their size, very inexpensive, though we have not obtained data sufficient to enable us to estimate their cost with full accuracy. The design appears calculated to afford a large amount of efficiency, while its freedom from any complicated machinery will ensure almost entire immunity from breakdown. In the journey to Eucador, the machines will have to be transported for the last twenty miles of it on mule-back. It was this necessity, no doubt, that induced the adoption of wood for the frames of these particular machines instead of iron. The light roofing shown is designed to guard against the cooling effects of the heavy rains we have named to be so constantly and unexpectedly experienced in Ecuador.

PLAN.

GAMARRA'S COFFEE DRYING MACHINE

**The Development of Field Artillery Fire.**—Major Hughes. Royal Artillery Instructor in Field Artillery, read a paper on October 11th, in the theatre of the Royal Artillery Institution, at Woolwich, on "Oakhampton Experiences in 1894," followed by a discussion, in which Colonel Marshall, Chief Instructor of Field Artillery, Colonel Ollivant, R.H.A., and others took part. Without going into the question of fire discipline, which has of late years been developed to an extent which makes artillery fire under service conditions much more formidable than in former years, we may notice one or two features. Success in hitting has been naturally greatly increased, not only by competition and prizes, but by the adoption of various devices to enable the guns to be fired under known conditions as to range and length of force, such as the deliberate advance of officers and markers under favourable circumstances, to take up position for each gun, and ascertain all possible data before the guns come into action, as well as the use of range finders, and of systematic trial firing, not independently, but for the benefit of the battery. On the whole, it has been felt latterly that we have fallen into the mistake of giving too much weight to the effect of infantry fire at long ranges. Tables showing the results of experiments made as to modern infantry fire at dummy guns and men certainly bore out the conclusion that at ranges over a thousand yards it would be absurd for guns to sacrifice any advantage obtained by exposing themselves to infantry fire. As compared with continental Powers, it appears that both the French and Italian field artillery fire more quickly than our own, owing to the circumstance that they carry shells forged, but in the still more important matter of success in hitting under service conditions we appear to compare favourably with them.

## THE MANCHESTER THIRLMERE WATERWORKS

### No. I.

ON the 13th inst. the inhabitants of Manchester, and of the district supplied with water from the Corporation reservoirs, entered into possession of the heritage for which they have been working for the last seventeen years. On that day the water from Thirlmere was turned on through a fountain in Albert-square, opposite the Town Hall.

Dr. Tatham, the late Medical Officer of Health, told the Corporation that, "if they would give the city a plentiful supply of water he would be responsible for the health of its inhabitants." Seeing that Manchester is now in a position to command at will a supply of water three times as large as she has hitherto enjoyed, the position of Medical Officer of Health must either be a very pleasant or a still more onerous one for the present holder; at any rate, the Council and ratepayers have placed the responsibility on his shoulders. To accomplish this an immense amount of work has had to be done. As is well-known to our readers, the late Mr. J. F. Bateman, F.R.S., was for many years the chief engineering adviser to the Corporation of Manchester on the question of water supply. He it was who designed and carried out the extensions to the waterworks, and made the Longden Dale Valley the chief source of supply. The Act for this scheme was obtained in 1847, and the works commenced in the following year. The original works have been added to from time to time, and a service reservoir in connection with them was completed only ten years ago.

The valley lies about twenty miles east of Manchester, and the drainage area covers 19,300 acres on the western slopes of the Pennine Range, varying from 500ft. to 1900ft. above Ordnance Datum. From this source Manchester was enabled to draw some 25,000,000 gallons daily, in addition to providing the compensation water demanded.

From these sources the city of Manchester has drawn its supply up to the present, and, in addition, has supplied the inhabitants of Salford and many other suburban towns, as well as the North Cheshire Water Company. The whole area, extending to upwards of eighty square miles, is supplied by gravitation. The total population provided for amounted to about 1,000,000 persons. The authorities outside the city were charged 7d. per 1000 gallons.

Prior to 1847 the water supply of Manchester was obtained from the limited sources of the Manchester and Salford Water Company, who had works on the river Medlock, now one of the foulest streams in the kingdom. These works were obtained from Sir Oswald Mosley, formerly Lord of the Manor of Manchester, and were added to by the construction of works at Gorton, and augmented by a supply from the Stockport Canal. The cost of the above works, including land, reservoirs, pipes, &c., has been £533,561; Longden Dale Works, £2,610,126; total, £3,143,126.

In 1851 the water was first delivered to Manchester from Longden Dale. The supply from the old works was about 3,500,000 gallons a day; but need for a supply of purer water in ample quantities was soon manifested in a largely extended demand, so that in a few years three times as much water was required. So long ago as 1868, Mr. Bateman sounded a note of warning, stating that the time during which a sufficient supply could be obtained from Longden Dale was limited. No action seems to have been taken until 1874, when, in a report, Mr. Bateman estimated that the annual increase and demand would be at the rate of 1,000,000 gallons a day, and could not be procured in the Derbyshire district. The Waterworks Committee and the Town Council generally took the matter up vigorously in 1875. At that time it was found that in dry weather the consumption was nearly 10,000,000 gallons a day, whereas the supply could only be reckoned at from 24,000,000 to 25,000,000 a day. Allowing for but little annual increase, before long the demand would exceed the supply. This was a serious matter, and required dealing with without delay. Mr. Bateman was called upon to report. He found that the districts east of Manchester had been absorbed to provide for the requirements of the populations near them, and advised that there was no district which could supply a sufficient quantity nearer than the Lake district of North Lancashire, Westmoreland, and Cumberland. He in the first instance recommended Ullswater as the head of the supply, and it being known that the town of Liverpool was in want of additional water, it was proposed that a single aqueduct should be constructed from Ullswater to Chorley, branching from thence to Liverpool and Manchester.

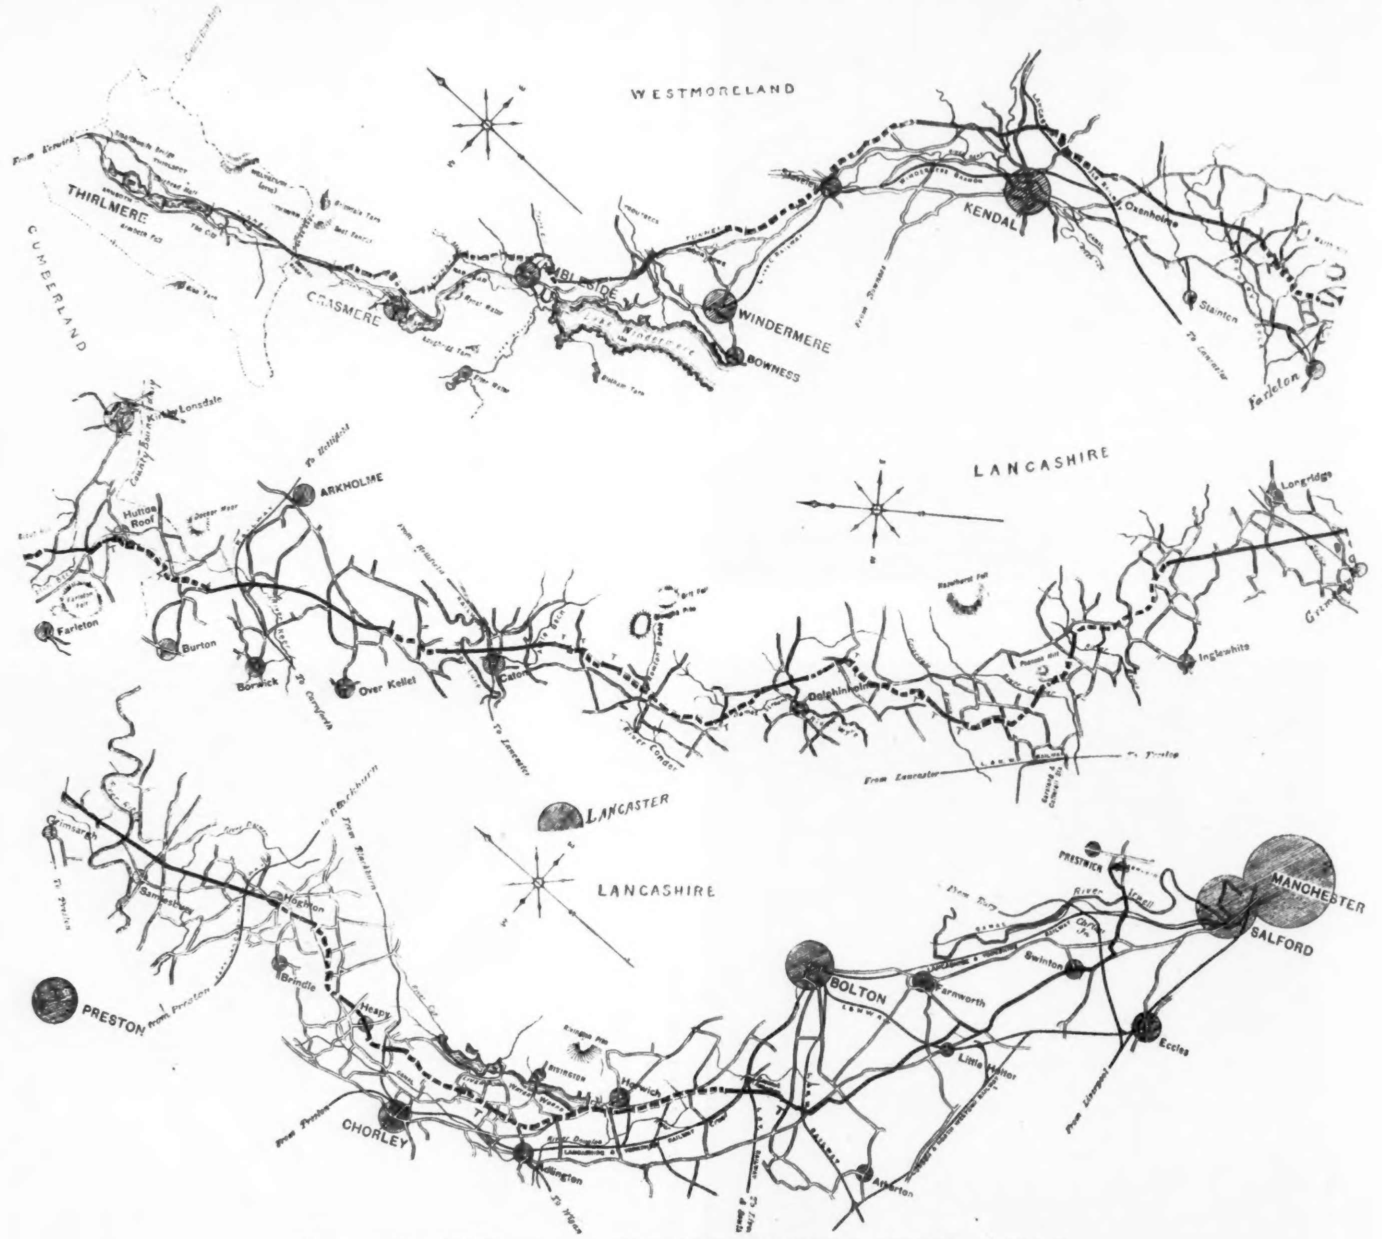
By adding the area of Hawes Water to that of Ullswater, it was estimated that a supply of 80,000,000 gallons a day could be obtained. To provide storage capacity it would only be necessary to vary the level of Ullswater 12ft., viz , 5ft. above, and 7ft. below the ordinary level of the lake. Hawes Water would have required raising 25ft. It would not, however, have been necessary to interfere with Hawes Water until the supply reached 55,000,000 gallons a day. The distance from Ullswater to Chorley is seventy-nine miles, the latter place being eighteen miles from the service reservoirs at Salford. No doubt it was the slight interference with the land on the margin of Ullswater that led Mr. Bateman to recommend this scheme instead of the Thirlmere one at the onset.

It was estimated that the works in the Lake district, and as far as Chorley, for the ultimate supply of 80,000,000 gallons a day, would cost £2,210,000. The half share to be incurred by Manchester would thus be £1,105,000, and the further works, to convey 40,000,000 gallons a day for ten miles, and the first instalment of 10,000,000 gallons a day was estimated at £346,000. Each additional 10,000,000 gallons would require 29½ miles of pipes, at an estimated cost of £352,000. The area of the Ullswater Lake is 2243 acres, and of its drainage area 36,000 acres.

It is understood that the authorities of Liverpool and Manchester had this proposal for the joint water supply under consideration, but no agreement was reached. On economical grounds this is very much to be regretted, for in the interval it has been necessary to construct large works for each city. The Vyrnwy Works of Liverpool are second only to the Thirlmere Works of Manchester, in the length of the conduit, and in both cases large costs have had to be incurred at once, in order that an increased supply may be obtainable in time to come when required. Had this capital expenditure been divided between the two cities, the present saving to the ratepayers would have been considerable. When it was found that the scheme was required for Manchester only, Thirlmere was selected as being a more suitable lake, and in every respect better fitted for the purpose. It is 56ft. higher than Ullswater, namely, 533ft. above O.D., is 335 acres in extent, and has a drainage area of 11,000 acres.

Mr. Bateman's report states that the ground is "exceedingly steep, yields beautiful water, and lies close to, if not in the heart of the heaviest rainfall. In the same year in which 65in. of rain fell at Hawes Water, 81½in. fell at Thirlmere"—an increase of 80 per cent. The estimated cost of Thirlmere to supply Manchester only was £170,000 less than if the supply was drawn from Ullswater.

On this page we give a map of the route of the Thirlmere Manchester Aqueduct. To enable us to give this map to a useful scale, it has been necessary to divide it



MAP, IN THREE LENGTHS, OF THE ROUTE OF THE MANCHESTER THIRLMERE AQUEDUCT into three lengths. The three parts are accompanied by cardinal point indicators, so that the direction of the parts forming the ninety-five miles of aqueduct made of tunnel, pipe, and cut and cover work, may be seen. To show the relative positions of the first, second, and third parts the name of the towns Farleton and Grimsargh are repeated.

The reservoirs in connection with Longden Dale are as follows:—

*Collecting and Storage Reservoirs at Longden Dale.*

WATER-TUBE BOILERS.—Mr. James Howden, of forced draught reputation, has challenged all makers of water-tube boilers to a thirty hours' trial, conducted by neutral experts, of the respective merits of cylindrical and water-tube boilers. The points to be determined are:—(1) Weight; (2) space occupied; (3) evaporative power; (4) economy, and 5th, waste of heat. The challenge is particularly directed at the Belleville boilers. The stakes are to be the expenses and cost of the boilers.

THE GREAT WESTERN RAILWAY AND THE SOUTH-WEST.—The Great Western Railway has arranged to run on and from Thursday, 1st November—Wednesday midnight—a new train from London to Plymouth for the accommodation of passengers, parcels, horses and carriages. The train will leave Paddington at 12.1[illegible] a.m. midnight daily, Sunday midnight excepted, and reach Exeter at [illegible]5 a.m. and Plymouth at 8.25 a.m, calling at Reading, Didcot, Swindon, Bath, Bristol, Taunton, and Newton Abbot, where it will connect with the 7.30 a.m. train, thence to Torquay and the [illegible]mouth Branch. The facilities thus afforded will enable business men to reach the West of England with the least possible expenditure of valuable time, the journey being performed during the night, and the new train will no doubt be largely appreciated, particularly as it has been decided to provide sleeping accommodation for first-class passengers. Passengers for Truro, Falmouth, and intermediate stations to Penzance, will proceed from Plymouth at 9.25 a.m., and the time allowed at that station will enable them to have breakfast before completing their journey. A through coach for Oxford will be provided on the new train from Paddington, and will be attached to a new train for Oxford, which will leave Didcot at 1.50 a.m. An additional train will leave Oxford at 1.10 a.m. for Didcot, where it will connect with the new midnight train from Paddington for the West. On and from the 1st November, the company will also run a new express merchandise train from Penzance to London, which will provide for the delivery of merchandise traffic from Cornwall in the metropolis on the day following dispatch. The new train will leave Penzance about 4.0 p.m. daily, Sundays excepted, and it will convey, either from the stations direct or from Truro and Plymouth—to which places feeder trains will be run—traffic from all intermediate stations and branches.

THE HULL AND DISTRICT INSTITUTE OF ENGINEERS AND NAVAL ARCHITECTS.—The first meeting of the present session, 1894-5, was held on Monday evening, the 15th inst., at the Parochial offices, Bond-street, the President, Mr. F. H. Pearson, being in the chair. After the usual preliminary business, which included the election of several new members, was completed, the President delivered a short inaugural address. During the course of his remarks, Mr. Pearson alluded to the extensive adoption of water-tube boilers for marine purposes, especially in vessels now being built for H.M. Navy. Though this type of boiler has only recently been introduced into British boats, it has been extensively used by the French for some years, nearly 100 of their war vessels being thus fitted, and at the present time twenty-four more vessels for that Navy, as well as nine for the Russian Navy and seven new Messageries Maritime steamers are being fitted with them. The British Government has given orders for upwards of thirty of the new vessels to be fitted with water-tube boilers, and several private firms are also trying them, so that it almost seems as if this type had come to stay, although the old tubular or Scotch type will die hard. The use of aluminium in shipbuilding was also commented upon, but the present cost of production is almost prohibitive. The prolonged and costly strikes that have taken place in different parts of the country during the year, the changes that have recently taken place in Hull shipping firms, and the present condition of the engineering and shipbuilding trades, were also dealt with. Following on his address, Mr. Pearson read a further paper on "The History of Hull Steam Shipping," the period being 1840 to 1850. The various descriptions of the vessels, launches, accidents, time of passages, rates of freight and passage money, wages, steamship companies, and the trade of the port in general during this period being most interesting and in many cases amusing, the whole showing that an immense amount of time must have been spent in research to secure such a complete record. The meeting closed with a vote of thanks to the President for his paper and address, moved by Mr. J. Spear and seconded by Mr. F. Somerscales.

## THE PARIS METROPOLITAN RAILWAY.

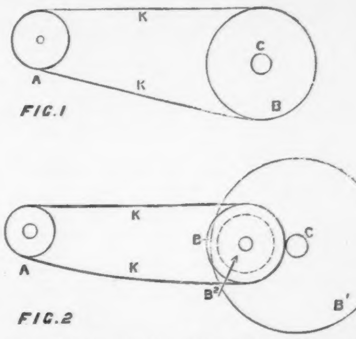
THERE seems to be little doubt now but that the underground railway in Paris will soon be put in hand. After being discussed for twenty years past, it has become absolutely necessary that something should be done to improve the facilities for passenger traffic in the city, since, unless the work is at once entered upon, it will be quite impossible to deal with the enormous traffic that is expected to take place during the period of the Exhibition of 1900. So far, the difficulties have arisen chiefly from the conflicting interests which seemed to place the project beyond the pale of settlement. The Government was in favour of the railways in Paris being constructed and worked by the great companies whose lines already serve the capital, while the municipal council insisted upon the metropolitan being taken over by a separate syndicate. It was only upon condition that the lines should be purely local that the council approved of the extension of the Sceaux Railway to the Place Medicis, which will be put in service in a few months, and the prolonging of the Moulineaux line to the Esplanade des Invalides, of which the works are now being carried out. The council likewise approved of the project for constructing the Berlier tubular tramway from the Bois de Boulogne to the Bois de Vincennes, and this project is now being considered by the Railway Commission of the Chamber of Deputies. If therefore the Government and the Municipal Council could come to an understanding there was every probability of the scheme being carried out, and it seems, indeed, as if the difficulties in this respect have been overcome. After having examined the systems at work in England, M. Barthou, the Minister of Public Works, has drawn up a plan which has just submitted to the Municipal Council with a view of securing from that body a free grant of land necessary for the building of the lines, and an exemption from octroi duty upon the material used in their construction. The project of M. Barthou seems to be the more serious, as it is less ambitious than the schemes previously under consideration. He does not propose to carry out the whole scheme at one operation, but is in favour of constructing two lines, one from north to south, and the other from east to west. When these are completed, it is expected that no difficulty will be experienced in a further extension of the system. The line traversing the city from north to south will leave the northern railway which communicates with the Ceinture, and passing the Nord and Est stations, will touch the Central Markets and will emerge from the tunnel at the Hotel de Ville; it will then take an easterly direction to cross the Seine, and, after passing the Halle-aux-Vins, will enter the tunnel under the Boulevard Saint Germain, and on reaching Cluny will turn to the right to join the Sceaux extension at the Place de Medicis, by which it will be again in communication with the Ceinture. The railway from east to west will utilise the high level line from Vincennes as far as the Gare de Lyon, and, passing by the Gare d'Orleans, will communicate with the north to south line at the Halle-aux-Vins. The section to Cluny will be used in common by both transversal railways, and from Cluny the east to west line will go by another tunnel to the Esplanade des Invalides, whence it will use the Moulineaux line as far as the Champ de Mars Station, at which point it will be connected with the Auteuil line near Muette. The total length of new lines to be constructed will be 15 kiloms, without counting the existing lines that will be used in the system. The cost of carrying out this work is estimated at four millions stetling. The railway companies are to have control of those connecting lines that already exist, but a separate syndicate is to be formed for working the railways to be constructed. As showing the utility of the proposed system, it may be mentioned that since the Compagnie du Nord connected its terminus with the Ceinture the number of passengers travelling between the Ceinture and the Gare du Nord during seven months has increased from 184,000 to 1,060,000.

LONDON ASSOCIATION OF FOREMEN ENGINEERS AND DRAUGHTSMEN.—The usual monthly meeting of this society was held in the K-room of the Cannon-street Hotel on Saturday, the 3rd inst., at 7 p.m., when, in the absence of the president, the vice-president, Mr. R. J. Cook, occupied the chair. After the usual financial and general business was over a paper was read by Mr. H. A. Parker, past-president, on "The City and South London Electric Railway."

BRISTOL CHANNEL INSTITUTE OF MARINE ENGINEERS.—A few years ago, mainly owing to the exertions of Prof. A. C. Powell, D.Sc., and the hospitality of the local University College, a branch of the Institute of Marine Engineers was established in Cardiff—the first branch, it is claimed, set up outside London of any of the professional societies which have the metropolis for their home. Under the title of the Bristol Channel centre, the new association gathered members from Newport, Swansea, and the neighbouring ports, held periodical meetings for the reading and discussion of papers of the same character as those presented to the parent Institute, and in course of time succeeded in making itself a place among the institutions of the district second only to that of the South Wales Institute of Engineers. On Saturday the winter session was opened with the annual dinner, at the Royal Hotel, and members and their guests reached the large and unexpected number of 350. Dr. Elliott, president of the Bristol Channel centre, was in the chair, and there were present the principal and several of the professors of the University College, a large number of engineers, marine and mechanical, and representatives of the shipping interest, together with Board of Trade and Lloyd's surveyors, and Mr. James Adamson, hon. sec. of the Marine Engineers' Institute in London. Dr. Elliott gave an interesting account of the growth and prosperity of the local centre, in responding to "The Institute of Marine Engineers," proposed by Dr. Maccormack, who claimed for this branch of engineering science that it had progressed fifty per cent. more than any other department, and that with the diffusion of knowledge by the papers and discussion of societies like these, it was no longer possible, as in 1867, for a man like Randolph, the maker of compound engines, to say to Mr. Denny, when asked for information, "Go and find out for yourself, and pay for it." A tribute to the services rendered to the Institute by the University College was paid by Mr. Adamson, the London honorary secretary, who mentioned that the local centre was increasing at such a rate that it was possible next year they would have a home and dining hall of their own. Principal Viriamur Jones, who replied for the College, claimed that technical education was being pressed forward in Glamorganshire and Monmouthshire, and particularly in Cardiff, in a manner which would compare favourably with any other part of the kingdom, while the engineering department of the College was being rapidly developed, and the practice of the profession taught to a large number of students. Next week the College would receive the great testing machine, which had cost £3000, and if only a fine building were given them, the authorities would soon challenge comparison with anything that had been done in any part of the world. An adequate building would require a quarter of a million sterling, and it was their intention to ask Government for a grant of £100,000.

## BICYCLE MECHANICAL ENGINEERING.

THE makers of the modern "cycle" have afforded mechanical engineers some useful hints in the construction of wheels and small bearings, and perhaps on other points in the construction of light machinery and the machine tools used for the purpose, but every now and then some of the bicycle makers do things and make things which detract very much from their reputation as mechanicians, and make us forget their services. Not long since some firms brought out an elliptical chain wheel for the crank spindle, and it was said that somebody or some shareholders paid a good deal for the patent for this beautiful device for obtaining a variable radius coincident with the variable push on the pedal. When we were explaining the fallacy of this thing to an ardent young cyclist but learner of mechanics at one of the cycle exhibitions, the exhibitor, who loudly claimed for the invention the advantages of greater speed and easier work, seemed to think we were anticipating the adverse proof which was later to be afforded by experience. He did not like the explanation. The last new cycling invention, for which very great things are claimed, is also to secure greater speed with less labour. The claims appear to have about as much to support them as the oval wheel had, and we would not mention this latest mechanical offence were it not that the names of one or two firms usually associated with well accepted machines are mentioned in connection with it, and a parent company is now to be formed for the development and working of the patents for this thing. It is known as the Boudard gear, and our readers will be almost sufficiently informed to satisfy themselves of the validity of the extraordinary claims made for it, when we tell them that the ordinary single chain wheel on the crank spindle of a bicycle is to be replaced by an internally geared wheel which drives a pinion on a second spindle, the other end of which carries the still necessary chain wheel, but reduced in size. The following diagrams will illustrate the difference. Fig. 1 represents the ordinary simple arrangement with a chain wheel B on a crank spindle C, and by the chain K driving a pinion A on the driving wheel hub. This is about as far as simplicity and directness can go. The Boudard gear neither wants nor has either of these qualifications usually regarded as so desirable in mechanics. In this remarkable device greater mechanical efficiency is obtained by adding to the mechanism by which a given end has hitherto been attained. Fig. 2 shows the arrangement. The chain wheel B of Fig. 1 is replaced by an internally toothed wheel $B^1$, which gears into the pinion $B^2$, shown by the dotted circle in the diagram, Fig. 2. It is on a spindle which carries the chain wheel B. Thus the friction of the internal toothed wheel B and the pinion $B_2$, and of the bearings of the spindle carrying the pinion $B^2$, and wheel B is all additional to that of the old common patentless arrangement shown in Fig. 1. To acquire this extra friction, there are introduced as extra parts, the internal cog-wheel, the pinion gearing into this wheel, the separate extra spindle, and one extra bearing or pair of bearings or ball races. Why these additions are to make the propulsion of a bicycle easier is not shown, although numerous statements are made, none of which are better than those which are usually used in the ordinary company prospectus. One ingenious supporter of the cause shows that internal gear should run with less friction than that of the ordinary forms of externally cogged gearing, but as that which is to be displaced by the new gear contains neither internal nor external gear, and as the internal gear of the new thing is altogether additional, the proposition as to more or less friction has not to be considered. It seems incredible that such things can be put forward, not only seriously, but in the expectation of attracting large sums of money from the public.

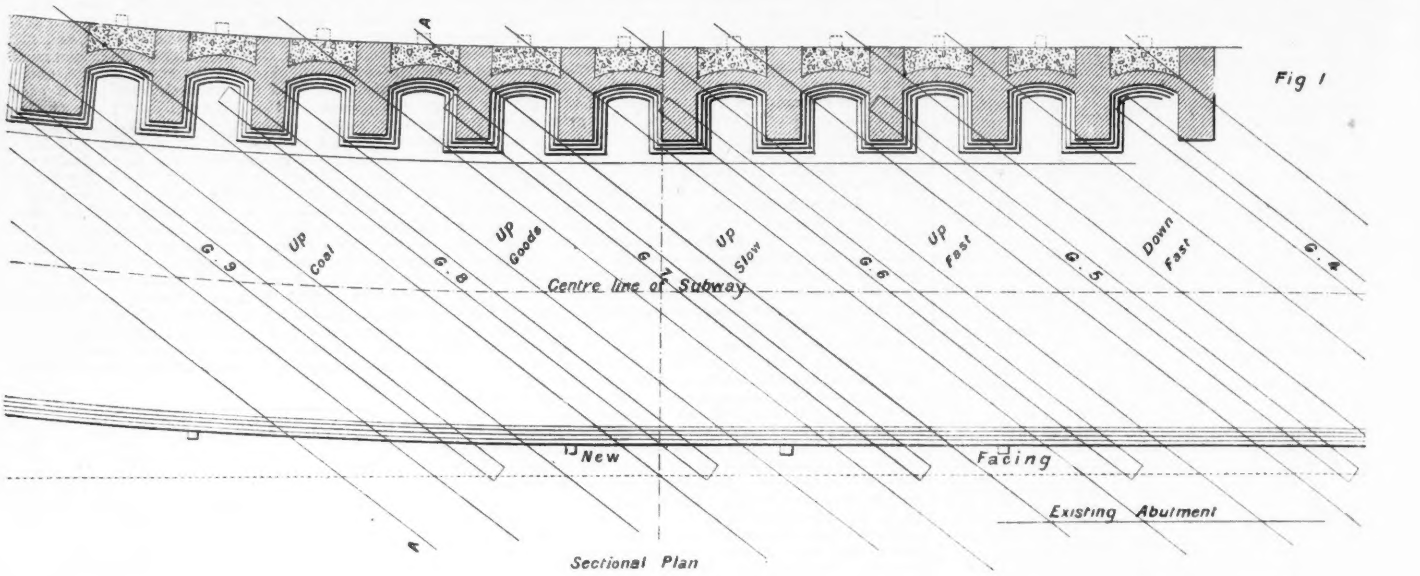


THE ORDINARY AND THE NEW CYCLE GEAR

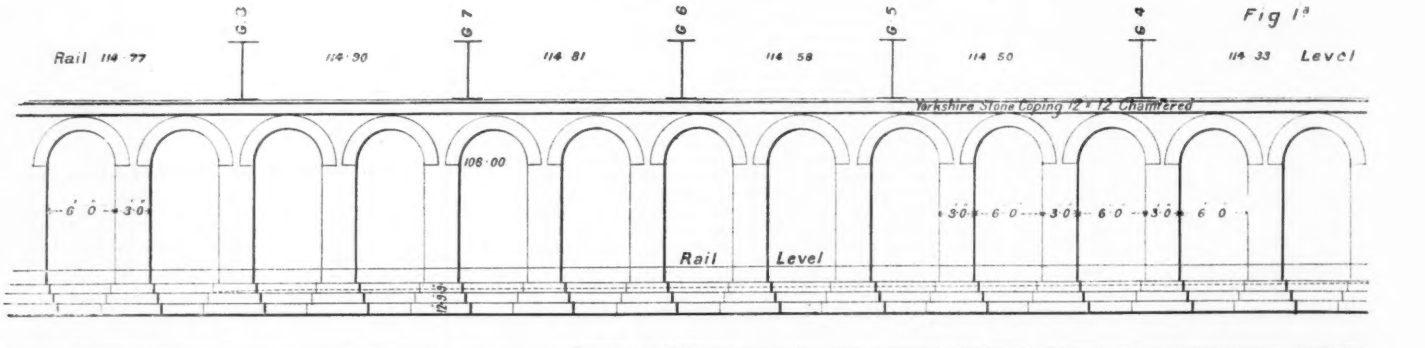
## GREAT NORTHERN RAILWAY.—WORKS IN CONNECTION WITH THE WIDENING OF THE LINE AT KING'S CROSS.

IN consequence of the extensive alterations the company have made to their terminus at King's Cross in the way of extra platforms and offices, it has been found necessary through the same occupying room used as sidings, to provide accommodation at Holloway for purposes of making up trains, storing and cleaning coaches, and other work incidental to the general passenger traffic formerly done at the terminal station. In order to carry out the new arrangement, trains of empty coaches have to be taken from the terminus and returned, after being cleaned, &c., at the new sidings. This, as a matter of course, increases the number of trains going to and from the points mentioned above. As the ordinary passenger service is already very heavy, any blocking of the line to enable a train to pass from the down to the up side on the same level would be a serious inconvenience to the working of the trains, and in misty weather, not unattended with some risk. To avoid any such inconvenience, the company have determined to cross from the one side to the other by means of a short subway, parallel with one already existing, and which is used for the service between the North London and Great Northern Railways. It was difficult to construct this subway, and still keep the traffic going without interruption, the most difficult being that part on the eastern side, and forming the approach to the goods and coal shunting sidings.

The means adopted to meet the different requirements were as follows: Before doing any part of the permanent structure a

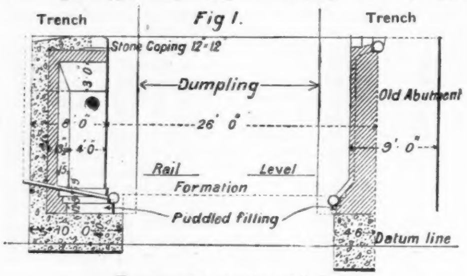


Sectional Plan

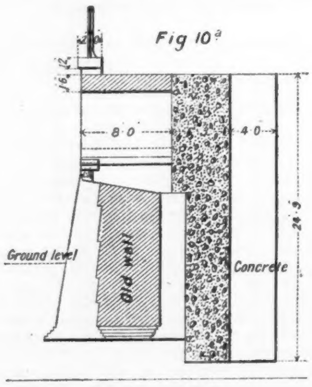


"The Engineer" Elevation of Abutment Swain Eng

platform of timbers, 8in. by 8in., with an average length of 14ft., was laid under the rails, forming the approach to the sidings directly over the line of the new abutment and also the pier, and some 15in. square longitudinal timbers under each of the main lines. In addition to the longitudinals, cast iron girders were put between the roads with cross timbers under the 15in. longitudes, placed 8ft. apart, as in consequence of the angle of skew, the bearing of the timbers would have been 21ft., although the width of the trench on the square only measured 12ft. In executing the work this proved a great convenience, as no propping of timbers under the lines of way was required, thus enabling the walls, Fig. 1, to be carried up to bedstone level without any stoppage. The trenches for the new abutment and strengthening the existing one were then proceeded with and the wall built to coping level. The new abutment is a combination of brick and concrete, the strengthening of the old one being all in brick. They are both faced throughout with Staffordshire blue brick, and all the work is set in Portland cement mortar. On the completion of the masonry, the timbers carrying the rails were packed on to the walls and all the cast iron girders removed and trenches cut to receive the permanent steelwork.



Transverse section at A. A

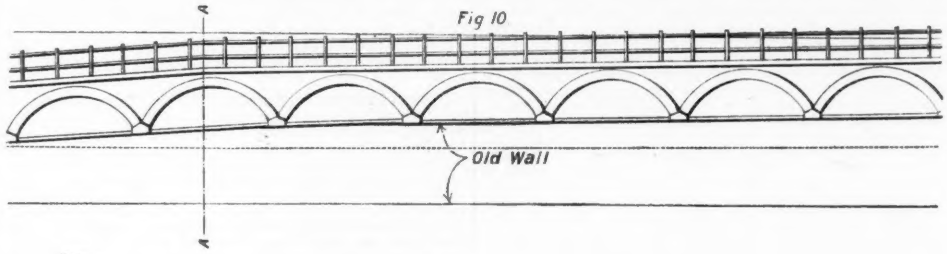


Section at A. A.

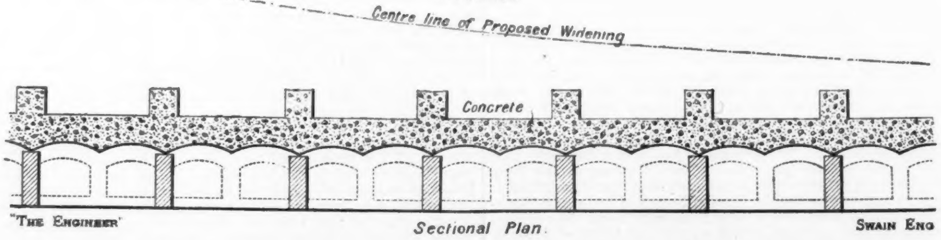
As the lines forming the approach to the shunting sidings could not be closed for many hours, and then only on Sunday, a gantry was constructed on the east side of the line—as shown on the plan between A and B. On this eight steel trollies, each carrying two hydraulic jacks, were placed, four on a side, and trussed bearers laid on the jack heads, to form a continuous bed for the steel flooring, as shown by the Figs. 2 and 3. The set of eight jacks were connected with a hydraulic pipe worked from one pump fixed on the end trolley—a view of one of these pumps is given in Fig. 5. The steelwork was then put together, and all riveted up, painted, and asphalted. This portion has an average length of 110ft. by 29ft. wide, and weighs about 200 tons. The time for running it into its final position was fixed for a Sunday, between 8 a.m. and 5 p.m. The heaviest part of the work was taking up the temporary timber flooring, which amounted to 1500 cubic feet, and excavating 300 cubic yards of earth, the materials to be removed representing 500 tons nearly, exclusive of permanent way. The new steelwork was drawn forward by three winches, the earth and timber being removed as the bridge came forward. When in position for lowering on to its bed the pressure was applied, the wedges on which it rested removed, and the whole thing lowered on to the bedstones. The ballast was then distributed, and the rails laid ready for the early Monday trains. The cost of this portion of the superstructure amounted to £18 16s. per ton of steel work fixed.

The remaining section carrying the eight main lines is constructed with ordinary plate girders, with flooring formed with steel troughing. Three methods of erection had to be resorted to in carrying out this part. The first line dealt with was a siding, which could be given up for some days without much inconvenience. The girders for this, together with the flooring, were erected *in situ*—no special feature in the operation presenting itself. The second line being a through goods could not be closed for many hours, therefore this section was put together by the side of the line at C, and when completed the lines were removed and the earth cleared away down to bedstone level, and the steelwork drawn into position and bolted to the part already fixed. This work was performed between 8 a.m. and 1 p.m. The third, fourth and fifth, being the down slow, down fast, and up fast passenger lines, had also to be done quickly. These sections were put together by the side of the line, as shown by Fig. 6, and drawn across to their respective lines, as shown by Figs. 7, 8, and 9, and then transferred to their bearings, the lines being taken up and the ground being excavated, while each portion of bridge was being transferred from the site of erection. The remaining three sections, consisting of the up slow passenger and the two up goods lines, were put together *in situ*, but as the lines could not be stopped for many hours, they could only be erected by degrees, the main girders being put on to their bearings on one Sunday, and the trough flooring in between fixed on succeeding ones. The cost per ton of steelwork fixed in the first portion was £18 4s.; for the second, £17; for the third, fourth, and fifth, £16 12s.; and the sixth, seventh, and eighth, £18; so that building the bridgework by the side of the line and hauling it into position proved to be the less costly, and interfered with the traffic the least.

The whole of the bridge-work is steel, the main girders being plate and I section. The flooring is made with corrugated troughing, 8½in. deep and ½in. thick. The troughs are filled in with asphalte concrete, with the upper surface covered with J. Cliffe's patent fibrous asphalte. All the bridge-work was made and erected by Messrs. A. Handyside and Co., of Derby.



Elevation



"The Engineer" Sectional Plan Swain Eng

After passing through the subway described above the lines take a sharp curve to the south, and join the main lines on the up side where it crosses the Hornsey-road. To enable this to be done an old retaining wall had to be strengthened and raised—an elevation and section of which is given in Fig. 10. The raised portion of wall is made with Portland cement concrete, in the proportion of one of cement to eight of Thames ballast, and Fletton brick faced with pressed blue Staffordshire bricks, all set in Portland cement mortar. The banks and filling behind the raised retaining wall and ballasting of permanent way is made of burnt clay ballast obtained from surplus earth from the excavations in trenches, &c.

The whole of the work has been carried out under Mr. R. Johnson, M. Inst. C.E., Mr. H. Lovatt being the contractor.

## RAILWAY MATTERS.

Fifteen miles of the German railway at Zanzibar have been completed, and the line will shortly be opened for traffic.

The Brooks Locomotive Works have received an order for thirty freight and thirty passenger locomotives for the Central Railroad of Brazil, fifteen of which will have Belpaire boilers. All will have copper fire-boxes, and all the wheels will have Krupp steel tires.

Two new strategic railways, which are to be shortly taken in hand, one leading from the Duchy of Baden into France, and the other from Rufach to Seheim, are calculated to faclitate the concentration of German forces opposite Belfort, which is regarded as a point threatening the whole of South Germany.

The Port Talbot Railway Act, obtained last session in Parliament, provides for making a line of railway sixteen miles long and serving three mineral valleys in Glamorganshire at present served only by the Great Western Railway. Miss Talbot, the owner of the docks at Port Talbot—which are to be considerably improved and enlarged—and of a large portion of the land for the railway, herself provides a large portion of the capital.

A short while ago the mail train on the Bengal and Nagpore Railway ran into a wild elephant which was straying along the line near Guilkhera Station. The engine having carried the animal about a hundred yards, then left the rails with the first five carriages. The elephant was thrown down a bank 60ft. high and was found dead at the bottom. No one in the train was injured, and no damage was done to the rolling stock or to the line. This was "bad for the coo."

A contract has been placed with Mr. Woolley, of Wrexham, for the construction of about eight miles of the Vale of Glamorgan Railway, which portion of the proposed line is at the Bridgend side of the route, and will provide employment for a year or two for a large staff of hands. Messrs. Pethick Brothers, the main contractors, are also approaching completion of the preliminary work at Barry, with a view of commencing the excavation of the large tunnel in Porthkerry Park.

Work on the proposed new line to compete with the Pennsylvania Railroad—the Loyalhanna and Youghiogheny—is to be vigorously pushed. The line, according to the *Railway News*, will run from Mehaffey, in the Clearfield coal region, to Sewickley, on the line of the Pittsburg, McKeesport, and Youghiogheny Railroad, and will connect with the Buffalo, Rochester, and Pittsburg line at Punxsutawney, and with the Shenango and Lake Erie road at Butler, and will make connection with Pittsburg over the Pittsburg and Erie, giving an outlet from the Connellsville region to the seaboard, the Lakes, and Canada.

A new carriage, of a class not in use before on the Great Northern (Ireland) Railway, or any other of the Irish lines, has been completed in the central workshops, Dundalk, and tried. It is constructed on the Pullman system, the outside framework of the carriage being of mahogany, 45ft. in length, and resting upon four couple of bogie wheels, with automatic brakes to all the wheels. The interior of the carriage is divided into five sections, the largest occupying about two-thirds of the space as a drawing-room car, and is fitted throughout in superb style. This carriage is for immediate use on the Dublin and Belfast limited mail.

The new railway from Uppingham to Seaton, 3½ miles long, on the Stamford, Peterborough, and Market Harborough branch of the London and North-Western Railway, at last connects the town of Uppingham, possessing an important public school, and having a weekly cattle market, with a railway system, all traffic having hitherto been by road to Seaton Station, on the London and North-Western Railway, or to Manton, on the Stamford and Oakham section of the Midland Railway. Owing to the altitude of the town, many cuttings and embankments were unavoidable, and in one case a long viaduct has been built. The total cost of construction was £30,000.

Another cable tramway has been recently completed in Australia, namely, the Ocean-street Cable Line at Sydney. A communication from that town, of August 25th, mentions it as about to be tested. The line was commenced in October, 1892, and has, it appears, cost altogether something like £160,000. The line has many curves upon its 2½ miles of length, and it is considered to be one which tests the system very severely. The cables altogether weigh 150 tons, and the working of the several lengths of cable, even without any car upon the lines, will require something like 250-horse power. The engines have been built by Messrs. Hudson Bros., of Granville, and are horizontal compound surface-condensing Spencer-Inglis Corliss engines. The cylinders are 24in. and 45in. diameter, with 5½ft. strokes. There are two of these engines, one being a stand-by. The main shaft carries a fly-wheel weighing 25 tons, and a rope drum, 7ft. in diameter, with thirty-six grooves for 2in. cotton ropes. The boilers are described as three multitubular under-fire boilers, each rated at 250-horse power, and working at 150 lb. per square inch pressure. Mr. Fischer, of the Department of the Engineer-in-chief for Railways, is the engineer of the undertaking.

Since the Dutch-Rhenish railways were transferred to the State on October 15th, 1890, the lines worked by the Maatschappij tot Exploitatie van Staatspoorwegen are the following:—Rotterdam-Dordrecht-Esschen, Amsterdam-Utrecht-'s Bosch-Breda-Esschen, Amsterdam-Gouda-Rotterdam, Den Haag-Voorburg (locaald.), Rotterdam-den Haag, Amsterdam-Breukelen-Utrecht, Amsterdam-Utrecht-Arnhem-Emmerik, Utrecht-Gouda-Rotterdam, Utrecht-Leiden, Rotterdam-Venlo, Moerdijk-L.-Zwaluwe-'s Bosch, Utrecht-'s Bosch-Boxtel, Vlissingen-Breda, Nijmegen-Tilburg, Nijmegen-Maastricht, Eindhoven-Luik, Nijmegen-Arnhem (voll. dienst), Arnhem-Zutphen-Deventer-Zwolle, Arnhem-Zutphen-Zwolle-Leeuwarden, Meppel-Groningen, Groningen-Delfzijl, Zutphen-Salzbergen voll. dienst, Zwolle-Gronau, Harlingen-Nieuweschans. This company was founded in 1863 for working the Dutch State Railways, and the head offices and works are at Utrecht. The office of Rijks Commissaris, or Government Commissioner, is at present vacant; but the Assistant-Commissioner is Mijnheer P. J. Breedveld. The general manager is M. J. L. Cluysenaer; the secretary, M. J. N. Nivel. Superintendent of the line, M. E. J. B. H. M. Engeringh; engineer-in-chief for permanent way and works, M. J. Kalff; and chief engineer for rolling stock, Mijnheer J. W. Stous Sloot.

It is stated that there is now every prospect of the scheme for the construction of an electric railway to the summit of Snowdon being carried out in a very short time. There are two companies formed, and, as owner of the land, Mr. Assheton-Smith, will take a leading part in the promotion of the project. The services of Mr. Duncan Fox, the engineer, have been secured, and his plans will probably be formed on the lines of those adopted for similiar railways on the Continent. Unless unforeseen circumstances arise, it is, says the *Liverpool Post*, confidently anticipated that with the advent of next season this railway will be an accomplished fact, thus adding considerably to the importance of Llanberis as one of the starting points for Snowdon. In conjunction with this interesting project the suggestion is pretty generally made that the North Wales Narrow Gauge Railway Company should extend their line from Rhyddu to Beddgelert, so that people making the ascent of Snowdon on the Llanberis side might descend on the Beddgelert side, and so have direct communication with all places on the London and North-Western Railway. A Bill for the extension of this line has already been passed, and it only requires a like enterprise on the part of the promoters to give to this picturesque district a boon which both the inhabitants and visitors have long looked forward to.

## NOTES AND MEMORANDA.

A method of connecting metal to earthenware is given in *The Scientific American* as follows:—The portion of the earthenware with which connection is to be made being unglazed, or the glaze having been removed, it is coated with plumbago, and placed in an electrolytic bath, whereby a firm metallic coating is obtained. The lead pipe is then soldered to this coating by a plumber's "wiped" joint. By this means are avoided the imperfect joints made with india-rubber sleeves, washers or putty.

In order to obtain incandescent lamp filaments which will stand a very high temperature, M. Baum proceeds as follows:—Organic fibres are treated with phosphate ammonia, hydrochlorate of ammonia, calcium chloride and magnesium chloride. At a known temperature, the salts of ammonia are volatilised, and the filament is formed of the precipitated porous phosphates of lime and magnesia. The filaments are afterwards strengthened with a solution of gelatine and dilute carbonate of lime.

Mr. Mondit, of Caen, has published a process for bronzing copper, which is briefly thus:—After the metal has been scoured, it is covered with the following mixture by means of a brush:—Castor oil, twenty parts; alcohol, eighty parts; soft soap, forty parts; water, forty parts. The mixture is left on till the required shade is obtained, then dried with hot sawdust, and coated with a very dilute varnish. The depth of tone can be regulated by the length of time the metal is exposed to the solution.

The new sextuple photographic telescope in the Yale Observatory, used in photographing meteoric displays, has six cameras together covering a field equal to 2400 full moons. Each camera carries a plate covering a space of 10 deg. square in the heavens, and the fields are so arranged as to touch each other at the edges, so that the total field will cover 600 square degrees. It will be used in connection with two single telescopes placed at a distance of two miles from the sextuple instrument, with electrical connections for simultaneous photography.

A recent Austrian patent for insulating material is as follows:—Ozokerite, asphalt, and amber are subjected to distillation in a closed still to a temperature of 400 deg. After the mass has been heated until gases, vapour, or oils cease to escape, it is allowed to cool. In that condition it is of pliable consistency, and may either be used alone or incorporated with other substances for insulating cables, such as resins, fats, or oils, the proportions of these being from 30 to 70 per cent. By this method those substances present in fossil resins which prejudice or deteriorate the insulating properties are removed.

In a paper which he recently read before the Scientific Congress at Paris, M. de Lapparent expressed the opinion that all mountains will vanish off the face of the earth in course of time. He declared that, if the actual natural forces at work upon our globe retain their present intensity, in 4,500,000 years all inequalities of surface will be levelled. He instanced as a striking example the reduction of the Ardennes, which were once a chain of the Alps, but which had already shrunk to their present dimensions at the outset of the Tertiary epoch. The Alps, he said, exemplified the youth, the Pyrenees the maturity, and the mountains of Provence the declining years of mountain ranges, while the central plateau of France was typical of their death and dissolution.

Two methods of covering aluminium with metallic films are given as follows in the *Journal* of the Chemical Society:—"Aluminium becomes covered with a hard film of copper on rubbing it with tin dipped in copper sulphate solution, the deposit increases in thickness if the coated metal is suspended in a dilute copper salt solution. Aluminium is covered with tin by rubbing it with brass moistened with solutions of certain tin salts, such as ammonium stannichloride, $SnCl_4 2NH_4Cl$; in this case, too, the deposit increases in thickness when the metal is suspended in a tin salt solution of suitable concentration. Aluminium which has been coated with copper as above described, when suspended in a solution of a tin salt, receives a coating of tin over the copper."

At the Angleur Company's Steel Works at Sclessin, on the left bank of the Meuse, the *American Manufacturer* says, coke for smelting is made on the ground from the small coal of the neighbouring collieries, partly washed and partly in the rough state, in a battery of 100 Coppee Menier ovens, about 30ft. long, 4½ft. high, and 17in. wide. The use of such very narrow ovens is rendered necessary by the deficient binding properties of the coal, owing to the low proportion of volatile matters present, so that a high heat quickly applied is required to produce a coherent coke. The surplus heat of the ovens is utilised in the firing of seven De Nayer boilers of 200-horse power each, which together with a similar series of Galloway boilers with outside combustion chambers fired by blast furnace gas, supply the whole of the steam for the blast furnace and Bessemer blowing engines.

A method of preparing hematite artificially is the introduction of Mr. H. Arctowski, who proceeds as follows:—"A current of ammonium chloride vapour when passed over oxide of iron, heated to dull redness, converts the oxide into crystalline hematite. Ferric oxide heated at 350 deg. absorbs ammonium chloride vapour, and melts to a black mass, from which ferric chloride soon distils. The residue absorbs water from the air, and is a mixture of ammonium chloride and ferric chloride. At 600 deg. the ferric oxide is partially converted into small crystals, and then mechanically absorbs ammonium chloride without melting. At 700 deg. the ferric oxide becomes crystalline. The crystals are of the same form as the hematite crystals from Elba. The gases of fumaroles contain ammonium chloride, and the fissures in the vicinity are generally covered with crystals of hematite."

In an address delivered before the American Association for the Advancement of Science, at its Brooklyn meeting, August 16th, the retiring president, Mr. William Harkness, said:—"Those who are not familiar with practical astronomy may wonder why the solar parallax can be got from Mars and Venus, and not from Mercury or the sun itself. The explanation depends on two facts—firstly, the nearest approach of these bodies to the earth is for Mars 33,874,000 miles, for Venus 23,654,000 miles, for Mercury 47,935,000 miles, and for the sun 91,239,000 miles. Consequently for us, Mars and Venus have very much larger parallaxes than Mercury or the sun, and of course the larger the parallax the easier it is to measure. Secondly, even the largest of these parallaxes must be determined within far less than one-tenth of a second of the truth; and while that degree of accuracy is possible in measuring short arcs, it is quite unattainable in long ones. Hence one of the most essential conditions for the successful measurement of parallaxes is that we shall be able to compare the place of the near body with that of a more distant one situated in the same region of the sky. In the case of Mars, that can always be done by making use of a neighbouring star, but when Venus is near the earth she is also so close to the sun that stars are not available, and consequently her parallax can be satisfactorily measured only when her position can be accurately referred to that of the sun; or, in other words, only during her transits across the sun's disc. But even when the two bodies to be compared are sufficiently near each other, we are still embarrassed by the fact that it is more difficult to measure the distance between the limb of a planet and a star or the limb of the sun, than it is to measure the distance between two stars; and since the discovery of so many asteroids, that circumstance has led to their use for determinations of the solar parallax. Some of these bodies approach within 75,230,000 miles of the earth's orbit, and as they look precisely like stars, the increased accuracy of pointing on them fully makes up for their greater distance, as compared with Mars or Venus."

## MISCELLANEA.

E question of the formation of a Chemical Department for India will be submitted to the Secretary of State during the current season.

The torpedo-boat destroyer Rocket, the first of three building for her Majesty's Government by Messrs. J. and G. Thomson, of Clydebank, attained on her preliminary trial, on Tuesday last at Skelmorlie, on the Clyde, a mean speed of 28¼ knots, equal to 32 53 statute miles.

The sixteenth annual Brewers' Exhibition and Market opens in the Islington Agricultural Hall on the 22nd inst. The number of exhibits will be exceptionally large, and will comprise the many kinds of machinery and various appliances for facilitating the carrying on of the trade.

Three Sheffield firms, Charles Cammell and Co., John Brown and Co., and Vickers, Sons, and Co., have received orders for the citadel and barbette armour of the first-class battleships Mars, Jupiter, Hannibal, Victorious, and Prince George. The total weight is 12,500 tons. The plates are to be Harveyed.

On Tuesday last Messrs. John I. Thornycroft and Co. launched the new torpedo-boat destroyer Ardent. She is 200ft. long, 19ft. beam, and will be fitted with engines and boilers of the same type as those supplied by them to her Majesty's ship Daring—which we recently illustrated—guaranteed to give her a speed of 27 knots.

In accordance with the wishes of the late Mr. Henry Faija, Mr. D. B. Butler will carry on the practice in his name for the benefit of the family. Mr. Butler was formerly associated with Mr. Faija for ten years as his chief assistant, but had subsequently held responsible positions in two cement works. At Mr. Faija's invitation and for the last three months of his life Mr. Butler had the entire charge and conduct of Mr. Faija's office and business.

Upon the completion of the defence works for the protection of the river Medway at Sheerness the Admiralty propose to also construct booms for the protection of Portsmouth and Devonport Harbours. The gunboats Mistletoe and Firm, which are being utilised in connection with the boom at Sheerness, have been completed for service, and arrangements are to be made for testing a section of the boom as early as possible, the boom being constructed of wire hawsers and baulks of timber.

The upper reservoir of the Swansea Waterworks was formally opened on the 12th inst. This undertaking was commenced in May, 1886, and completed by December, 1891, since which time the opening has been delayed by litigation. The water area of the reservoir is thirty-five acres, the contents being 305,464,770 gallons, and the greatest depth 68ft. This important work has been carried out under the superintendence of the borough engineer, Mr. Wyrill, at a cost of £101,185.

In connection with the new American liners St. Louis and St. Paul, now building by Cramp Brothers, it was originally intended that the boilers of these vessels should be fitted with Purves' furnaces. American sentiment, however, with regard to the ships being entirely built at home asserted itself, with the result that corrugated furnaces have been supplied by American makers at what must have been a losing price. On the other hand, the St. Paul is to have Serve tubes, which appears to us a little inconsistent.

An application has been recently made to the Local Government Board for borrowing powers for some additions to the Ossett Sewage Works. Their inspector, however, reported that the sewage was being merely treated with lime, the land filtration having been discontinued. Consequently, the sanction to the loan was withheld, and the Ossett Town Council were requested to submit comprehensive proposals for the improvement of the works. The sewage is one of the very worst in the kingdom, being largely woollen trade refuse of a most changeable and refractory kind. The Council have engaged the services of Mr. M. Paterson, of Bradford, the engineer who nearly twenty years ago carried out the sewage works, with the main drainage of the district.

A meeting of the Consultative Council of the Building Trades Exhibition, 1895, was held on the 12th inst., Mr. Banister Fletcher, F.R.I.B.A., in the chair. The honorary secretary, Mr. T. Freeman, F.G S, read the report on last year's exhibition, which was satisfactory, and the council agreed that the forthcoming exhibition should be continued on the same lines. It was stated during the course of the meeting that architects were perfectly satisfied with the display at last year's exhibition, and the exhibitors were unanimously of opinion that their exhibits had proved eminently advantageous from a business point of view. The council for the ensuing year had been considerably added to, and it was confidently anticipated that next year would prove one of the finest exhibitions of the kind that had ever been held.

A useful table, showing graphically the dimensions, equivalent conductors, resistances, and weights of pure copper wires and cables, and the fall of potential and approximate rise of temperature of any wire, has been published by Messrs. W. T. Glover and Company, as designed by Mr. A. H. Howard. Messrs. Glover and Company, *i.e*, Mr. Henry Edmunds, accompany the table, which is large enough for easy reading, with the necessary directions for reading the dimensions or quantities obtainable in figures from the graphic diagram. Every direction seems to be perfectly clear, with perhaps the exception of that for the curves which represent rise of temperature of insulated wires in wooden casings. The table is one which will save a great deal of calculation and time, and affords an excellent check on calculated values.

M. Hospitalier, a well-known French electrician and writer, has drawn attention to the errors of language in French public documents relating to scientific matters. Thus, says the *Globe*, in Acts relating to the sale of land, the superficies is given in metres instead of square metres; the Bureau des Longitudes expresses the value of acceleration due to gravity in a falling body in metres instead of "metres per second." The word force is used for "work," and work for "power." All nations exhibit the same confusion in the use of scientific terms, which are often imperfectly understood, even by so-called experts, and all nations adopt foreign expressions instead of inventing their own. It is nevertheless true that in scientific language there should be no synonyms; one word should be dedicated to one thing, and have a perfectly definite meaning. It is poverty rather than wealth of words that science demands. Where compound words are required, they should be formed according to a strict rule, and always used in their entirety.

After many breakdowns, H.M. cruiser Fox has at last made a successful trip under forced draught She indicated 9063-horse power, or 63 beyond the specification, which gave a mean log speed of 20 knots. During the run a trial was made of Messrs. Cutmore's system for effecting audible voice-pipe communication between the bridge and the engine-room. The orders, notwithstanding the noise of the machinery, were distinctly heard. In this invention the sound is magnified first by means of a cone fixed in the mouthpiece, and secondly by silver tongues placed in every angle and bend of the voice pipe. Various subsidiary inventions have been utilised, such as by means of a commutator, which works on the pistol-revolver principle, converging orders from twenty different points of the ship to the engine-room; but the primary advantage of the apparatus is that the sound of the human voice can be transmitted with certainty. It is probable that this system will now be generally adopted in H M. ships.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

J. W. H. (Brixton).—*(1) The engines are identical save in the cylinders. (2) Yes.*

J. D. AND CO. (Traction Engines).—*The author of the letter to which you refer gave his name and address—see page 275.*

T. E.—*You do not require any piping. If you turn down the end of your exhaust pipe over the water in the tank so that the exhaust steam blows down on it, you can heat the water 180 deg. to 200 deg.*

B. (Blomfield-street).—*Have you considered the cost? Have you considered what would happen to the plates of a boiler into which you pumped a strong saline solution as feed? The idea is wholly unpractical from first to last.*

ENTROPY.—*Many persons have wasted money in forcing air into boilers. There is no economical advantage to be obtained even in theory, and practice has in this case always proved the truth of theory. There are references to the subject in back numbers of* THE ENGINEER, *which are out of print.*

### CORROSION OF BOILERS.

(*To the Editor of The Engineer.*)

SIR,—Can any correspondent refer me to any case of boiler corrosion due to sulphate of soda in water taken from a river?

London, October 10th. HIGH-PRESSURE STEAM.

### FISH HOOK MAKING MACHINERY.

(*To the Editor of The Engineer.*)

SIR,—I shall be much obliged to any reader who will tell me where I can obtain the necessary machinery for making fish hooks. S. F. O.

October 17th.

### CHROME ORE.

(*To the Editor of The Engineer.*)

SIR,—Would any correspondent kindly answer the following questions?—(1) Who are the best firms who purchase chrome ore? (2) What is the present current price landed c.i.f for chrome ore showing from 65 per cent. to 78½ per cent. of chromite? (3) Is there a good demand? (4) What ores are the chief constituents in (*a*) yellow metal, (*b*) anti-friction metal? W. C. W.

Wellington, New Zealand, August 27th.

## SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

| | |
|---|---|
| *Half-yearly (including double number)* .. .. | £0 14s. 6d. |
| *Yearly (including two double numbers)*.. .. | £1 9s. 0d. |

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* THE ENGINEER *is registered for transmission abroad.*

*A complete set of* THE ENGINEER *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

| | |
|---|---|
| THIN PAPER COPIES— | |
| *Half-yearly* .. .. .. .. .. .. .. .. | £0 18s. 0d. |
| *Yearly* .. .. .. .. .. .. .. .. .. | £1 16s. 0d. |
| THICK PAPER COPIES— | |
| *Half-yearly* .. .. .. .. .. .. .. .. | £1 0s. 3d. |
| *Yearly* .. .. .. .. .. .. .. .. .. | £2 0s. 6d. |

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

## ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* THE ENGINEER.

### MEETINGS NEXT WEEK.

INSTITUTION OF MARINE ENGINEERS.—Wednesday, October 24th. Formal opening of the extension of premises by the President. Members will assemble at 7.30 p.m. in the Lower Room, where the inaugural address will be delivered.

INSTITUTION OF MECHANICAL ENGINEERS.—Wednesday and Thursday, October 24th and 25th, at 25, Great George-street, Westminster, at 7.30 p.m. Papers: "The Manufacture of Standard Screws for Machine-made Watches," by Mr. Charles J. Hewitt, of Prescot, on Wednesday; "Drilling Machines for Cylindrical Boiler Shells," by Mr. Samuel Dixon, of Manchester, on Thursday.

# THE ENGINEER.

*OCTOBER* 19, 1894.

### RAILWAYS AND THE BOARD OF TRADE.

RIGHTLY or wrongly, many persons traders and others, hold that the action of the Board of Trade in all that relates to railways, their construction and working, is prejudicial to commerce, oppressive and unsatisfactory. Such charges are made by persons of sufficient influence to give them importance. The railway companies and their officials hold their peace and refuse to express an opinion. It is worth while to consider some of the facts which are more or less beyond dispute, and so arrive at the reasonableness or emptiness of the charges in question. These charges imply that the Board of Trade or its inspectors insist on an unnecessary and costly method of working branch and narrow gauge lines; that hard-and-fast rules are applied without intelligence or discrimination; and that there is no sympathy between the Board on the one hand, and the railway companies and trading community on the other. There are besides questions concerning bye-laws, terminal charges, rates, and other money matters, with which it would be to some extent beyond our province to deal. We propose to confine ourselves to the consideration of the action of the Board of Trade in what may be termed matters mechanical, and we may say at the outset that while we are very far from echoing the complaints so freely made, not unfrequently by wholly irresponsible persons, we hold on the other hand, that it is advisable that the position as it stands should be examined and revised.

The action of the Board of Trade is mainly exerted by its inspectors. A line cannot be opened for traffic until it has been passed by one or other of these gentlemen; and it seems to us beyond doubt that they demand for a small branch line the same general excellence that is needed on a main road. Dozens of examples of this might be cited—as, for instance, a case in which there was only one engine and train used on a branch line. This had been worked for years, without accident and with perfect success, with three trains each way per day, until one day an inspector insisted that the little terminal station should be provided with an elaborate system of signals at a very considerable expense. When the signals were completed and had been passed, they were fixed at "danger," and no one ever troubled his head about them subsequently. Roads on which the speed is never intended to exceed thirty miles an hour have to be sleepered and ballasted and made with all the heavy expenditure needed on a main line over which express trains thunder at sixty miles an hour. The result is that the cost of a railway becomes prohibitive. In other countries—notably in the United States—cheap lines are made which serve an excellent purpose; but there is no Board of Trade there to interfere. It may be that the officers of the Board have no choice. On the other hand, it is possible that they exert their authority just as they please, without the smallest consideration for the wants of the country. They virtually tell farmers and traders, "You shall have a first-class line or no line at all." Whether a line is to cost £5000 a mile or £15,000 is all one to them. They care nothing for the outlay. All that they demand is the nearest approach to perfection. With nothing less will they be satisfied. In its way no doubt this is all very well, but it is carrying the demand for excellence so far that it may be ruinous. It is as though Government insisted that we should all use Turkey carpets or go without carpets altogether. After everything has been said that need be said about the rules and the Acts of Parliament under which the Board of Trade discharges its functions, the whole ground is far from having been covered. Beyond question a great deal of power rests in the hands of the inspectors. To all intents and purposes they are all-powerful. No railway company thinks of appealing against the decision of any one of these gentlemen—possibly because it is so difficult to know to whom the appeal can be made. Ultimately we suppose it could be addressed to Parliament, which is tantamount to saying that it cannot be made at all. Now it so happens that for some reason not very easily comprehended all the inspectors are Royal Engineers. They rank as majors, colonels, or generals. In a word, they are military men with a military training, and not possessed of any special knowledge of railways or railway working other than that which they pick up in the course of the discharge of their functions. It goes without saying that they are one and all highly honourable men. What they think, and the general nature of their methods of reasoning about railway matters and railway men, can easily be gathered from the published reports of inquiries into railway accidents. Reading them as they come out for a series of years teaches the reader a good deal about those who wrote them. We learn, for example, that whenever a railway accident occurs, some one must be in fault. The preconceived idea is that a species of crime has been committed, and the criminal must be sought and found. In some of the reports we find it admitted now and then in a very hesitating fashion, that it is possible a man may make a mistake without being guilty of aggravated manslaughter; but such a concession to public opinion is rare. Again, it will be found that one inspector always takes it for granted when a collision occurs that an engine driver has been in fault; another throws the blame on a signalman. We have, indeed, before reading a report only to look at the signature to be able to say what the drift of the inquiry will be, and what the verdict. When it is obviously impossible to say that either a driver or a signalman is in fault, then the railway company must be blamed, and the blame is not infrequently absurd. Not long since a collision occurred of no great importance. It arose from a number of small causes all contributing to the same end. The inspector was hard up to find anyone in particular to blame, so he laid the fault on a lofty distant signal, which had been in work for more than twenty years, and "advised" its instant removal to another place. The fact that the existing position had been sanctioned by the Board of Trade, and that no complaint had been made for twenty years, went for nothing. Recently some of the inspectors found in long hours an excuse for everything. This long hour idea is worked in a most unintelligent way. An express driver takes his engine 120 miles down the country in the morning. The run accomplished, he has little or no further work to do until the evening, when he takes an up train to town with the same engine. From the time when he came on duty until he signs off is, say, ten hours, his actual working time is not five hours. If an accident occurs towards the end of the day we are told directly, or by implication, that it was brought about by the fatigue of the overworked driver. As regards the question of continuous brakes nothing can be more unsatisfactory than the attitude assumed by the Board of Trade. The continuous brake is evidently still regarded, after twenty years of service, as something dangerous and untrustworthy, and an absurd regulation is in force that no driver shall ever use the continuous brake on entering a terminal station. At first sight it seems that the Board of Trade inspectors believe that a hand brake on a tender, and two or three others in guards' vans, can do that which the automatic brake applied throughout a train cannot do. This, however, is not really the belief of the inspectors. What they mean to say is that trains should not be allowed to enter terminal stations at high speed, but for some inscrutable reason they prefer to use the elliptical method of phrasing, and say that only the hand brake shall be used to stop a train in a terminal station.

The railway companies assert, and not without reason we think, that the action of the Board of Trade is often vexatious, and that it entails a great and useless outlay. We have no reason to doubt that the accusation is largely well founded. We do not see how it can be otherwise. Officers in the Royal Engineers however considerable their professional attainments and keen their sense of duty, can scarcely be in touch with either traders' or railway companies. They may, and no doubt do, insist on taking care of the public to an extent which is not wanted or warranted by the facts. They are apparently impressed with the notion that a railway company is a more or less dangerous and wicked institution, which, unless carefully watched, will destroy immense quantities of it own property by gross or even criminal carelessness. They hold that signalmen are as a class so vicious that unless watched with precaution they will rather wreck a train than lose their supper. Engine drivers are so depraved that they think nothing of running past signals, even though they thereby incur the imminent risk of a dreadful death. In a word, the theory of the railway department of the Board seems to be on all fours with that of the marine department, which holds that the shipowner can do no good thing. We in no way blame the Royal Engineer officers who now look after our railways. They represent a system, and the system is bad, but they are not in fault. They act conscientiously according to their knowledge and training. That their influence is repeatedly exerted for good is quite beyond question, but we hold that the time has arrived for inquiry into the relations of the railway companies and the Board of Trade. There is a clamour for greater facilities of transport, and it is asserted that the Board of Trade stops the way. The truth or falsehood of the statement ought to be made plain by inquiry and investigation. Select committees are the rule. Let us have one to inquire into the relations of the railways and the Board of Trade. For ourselves, we hold that a large infusion of the civilian element would prove of great advantage. In the natural course of events, most of the officers now acting as inspectors will have to retire within the next few years, full of years and of honour. They should be replaced by those possessing experience in railway working, and able to discriminate between what is necessary for the safety of the public and that grandmotherly carefulness which insists, as we have said, that it is better to have no railways whatever than incur such risks as no other nation on earth hesitates to face.

### THE INSPECTION OF RAILWAY BRIDGES IN INDIA.

LAST year the Government of India issued rules as to the strength and loading of iron and steel bridges, for the guidance of officers entrusted with the duty of inspecting new railways. These rules were adopted after prolonged consideration, and were submitted for criticism to all the principal railway engineers in India as well as to the Secretary of State's advisers at home. They deserve the attention of English engineers both because Indian bridgework will have to be built under these rules, and also because some move in the same direction will probably be made on the part of our Government sooner or later. The present Board of Trade rules are so antiquated as to be practically useless. The new Indian rules are as follows:—(1) For any member of a railway bridge of wrought iron or steel, the total working load is to be taken as the greatest moving load, multiplied by a coefficient and added to the actual fixed load. (2) The coefficient to be used for this purpose is 2·0 in all cases, except for the upper and lower booms of triangulated girders, for which a coefficient of 1·5 may be used. (3) The stress per square inch, either in tension or compression, due to the total working load thus calculated, is not to exceed the following:—Wrought iron, 7 tons; steel, 9 tons. (4) The working stress per square inch given above, whether for tension or compression, is to be taken on the net available area at the weakest part of the member of the structure to which it is applied, after deducting all holes for rivets, pins, bolts, &c. (5) For members in compression, the working stress given above is subject to such reduction as may be necessary according to column formula. (6) For the purposes of this rule, "fixed load" is to be taken to mean the weight of the structure itself, with roadway, flooring, ballast, permanent way, &c., complete. (See also "wind-pressure" below.) "Moving load" to be taken as follows:—(*a*) A train load for each line of rails calculated as specified under "train load" below. (*b*) If there be a road or footway in addition to, and distinct from, the railway, an additional moving load of four tons per 100 sq. ft. of such road or footway. For the purpose of calculating the train load to be allowed for on each line of rails, the "type train" is to consist of two engines with a train of loaded wagons taken at a uniform weight per foot run on the 5ft. 6in. gauge, 1·2 tons; on the metre gauge, 0·8 tons. The engines are to be taken as running either in the ordinary way or coupled head to head, and occupying any position in the train. To facilitate the determination of the stresses which may be produced by the "type train," a diagram of a "type engine" is given in an appendix. It is to be understood that this diagram does not represent any actual engine, but an imaginary engine so designed as to produce on a bridge the most severe effect practicable under the specification. The amount of wind pressure on a railway bridge is to be calculated on the assumption that the maximum normal pressure may be one and a-half tons per 100 square feet of surface exposed, the surface exposed to be reckoned as follows:—(*a*) A train surface calculated on a height of 13ft. 6in. on the 5ft. 6in. gauge, or 11ft. on the metre gauge, multiplied by the total length of the girder. (*b*) The actual surface—as seen in elevation—of that portion of one girder which may be below rail level, or at a height above rail level of more than 13ft. 6in. on the 5ft. 6in. gauge, or 11ft. on the metre gauge. Also (*c*) In the case of triangulated girders, the actual vertical surface—as seen in elevation—of that portion of the leeward girder which may be below rail level, or at a height above rail level of more than 13ft. 6in. on the 5ft. 6in. gauge, or 11ft. on the metre gauge. The total wind pressure thus calculated is to be provided for by a proper system of wind-bracing or floor-plating, and its effect taken into account as forming a part of the stress on the chords of the main girders. Proper arrangements must also be made at the girder ends to secure sufficient stiffness to resist racking action, where diagonal stiffeners are not used. Wind pressure is to be treated as "fixed load," and its effects on the different members of the structure is to be allowed for as provided in the rule for "Maximum Permissible Stress."

In the appendices following the rules, particulars are given of the engine loads allowed, and a "type" tank-engine is represented, which is to be used for the purpose of calculation. For the 5ft. 6in. gauge this engine has eight coupled wheels, with 15 tons on each axle; it measures 32ft. over buffers. For the metre gauge the engine has eight coupled wheels with eight tons on each axle, and measures 24ft. over buffers. It would facilitate calculation, without any sacrifice of accuracy, if a uniform load per foot extending over a given distance, corresponding to the length of two engines, had been prescribed instead of definite axle loads. Cross girders would then have required a specification of the load they should be designed for to vary with the spacing. No one can say what the distribution of loads on engine wheels will be twenty years hence, and it is a useless pretence to imagine an exact distribution of the load on axles at definite distances. Assuming, for the moment, that it was the right policy to issue rules laying down hard-and-fast maximum limits of stress under given assumed loads, and that these rules had to be compressed within the compass of so many lines, we are inclined to think that the rules above quoted are about as reasonable and clear as such conditions would allow. This, we take it, is the meaning of the approval expressed by a large majority of the engineers consulted on the subject. We may observe, in passing, however, that this approval should not be made too much of. A set of draft rules were drawn up by the Government, printed, and sent round for remarks. The criticisms and proposed amendments were not, so far as we know, submitted to the same body of engineers for consideration, but the approval of the rules as originally drafted was inferred from the fact that, taking the rules one by one, each rule was approved by a large majority. It does not follow, however, that some of the amendments would not have been carried if they had been submitted in the same way. The most important questions raised by these rules, to our mind are, firstly, whether it is wise to lay down definite limits of stress and load applicable to all railways independently of the nature of the traffic, the nature of the iron or steel employed, and other circumstances; and secondly, whether, if such rules are necessary, they do not need, for efficiency, to be much more elaborate and particular.

We do not intend here to enter on the very wide question of whether Government inspection of such structures is a desirable thing. For good or evil it exists, and is likely to continue. We should like to see it made more of a real safeguard to the public, and less of a harassing and expensive burden to railways of small traffic. These two objects are not, we believe, incompatible, but such rules as these now in force in India serve neither one purpose nor the other. A bridge might fully comply with these rules, and yet be dangerously weak in a dozen different ways. On the other hand, a bridge might be absolutely safe for the traffic it was built to carry, and yet require a large additional expenditure to bring it up to the standard of the rules. India is the last country in the world where extravagance in railway expenditure is justifiable, and a policy which compels every line to be built and equipped on a standard only really required by the most important roads involves extravagance of the most serious kind. We quite admit, however, that inspecting officers are not to be left to their own devices in such a matter as bridge stresses. The rational way, it seems to us, of securing the safety of the public would be to establish some such requirements as the following:—(1) Before a railway is opened for traffic, copies of the working drawings of each bridge, with complete calculations of stress, copies of tests of materials, and all other necessary data, shall be supplied to the Government, and certified as correct by the chief engineer of the railway, and shall be verified by the inspecting officer, who shall also make such tests as may be desirable. (2) Before the work on any bridge is commenced, the drawings may be submitted for approval, so that it will only remain, when the work is finished, to verify that it has been properly carried out in accordance with the approved design. (3) The permissible loads and speeds on any new railway will be determined before sanction is given to the line; and for the guidance of the engineer in preparing bridge designs the Government will, if requested, decide beforehand what stress, as a fraction of the breaking strength of the material, will be sanctioned for the various parts of the bridges on the line, under the loads agreed on at the maximum permitted speed.

For the purpose of carrying out these regulations the Government should have a competent officer specially deputed to the task of making a really effective and independent examination of the designs submitted. It would not be his business to criticise or amend in any way, unless where there was actual demonstrable weakness. His task would be immensely simplified by being able to call on the railway engineer to provide him with stress diagrams and calculations, since it is far easier to check the correctness of such calculations than to make them afresh. If, however, each of the many railway inspectors in India is to calculate the strength of each bridge on the line he inspects and certify to its strength, and if rules for stress and loads are to be given him, such rules, in our opinion, should go much more into detail than do these Indian rules. The author of them appears to make the common mistake of confounding brevity with simplicity. Suppose, for instance, some separate rules had been given for plate girders, would the rules then have been less simple? Not in the least. The plate-girder rules would simply be non-existent for the purpose of inspecting triangulated girders. If the inspector had to carry these rules in his head we could understand the sacrifice of efficiency to brevity, but we understand it on no other ground. These rules govern the design of all railway bridges in India—where bridgework forms a larger item in railway construction than it does in most countries—and one would have thought that the object of securing the most efficient bridges at the lowest cost was far more important than that of cutting down the rules to as few words as possible. To pick out one or two of the most conspicuous disadvantages of this process of compression, we observe, first, that nothing is said about the strength of fastenings. The inspector, we presume, will have to examine the bridge as regards the proper design of joints if he examines the design at all. Why is it more necessary to give him a rule for the stress on bars than to give him one for rivets? Then Rule 2 seems to us much too rough-and-ready. It draws an unjustifiable distinction between, say, the end diagonal of a triangulated girder and the adjoining length of boom. The cross-girders and the end diagonals of the main girders are assumed by it to be in the same condition as regards the dynamic effect of moving load, which is far from being the case. The materials of which the bridge is built are not alluded to at all except as "wrought iron" and "steel." To be effective, such rules ought to be a complete specification such as is issued by an American railway company in inviting designs and tenders for a bridge. Such detailed rules would assist and not hamper the inspector. The present rules may probably be regarded as a step in that direction.

◆

### COAL MINING MACHINES.

In the reports of the State Inspectors of Mines for Illinois there are some facts given that should be of interest to this country, and that carry further forward the figures we gave a year ago in The Engineer. They refer to the use of mining machines in the coal mines of the State named. Last year it appears that the number of the mining machines in use in the coal mines of Illinois had increased to 310, or an increase of 69 in the two last years. There are seven kinds of machines in use, the Harrison type being by far the most numerous, and next the Ingersoll-Sergeant seems to be numerically preferred. These machines are in use in forty-one mines, so that there are on the average more than thirteen machines in each of the mines. The yield of coal was just about one-fourth of the total produced in the State—over 4,595,000 tons in the year, so that there was an output that is now large enough to give at least some idea of the relative cost of machine mining. The first of the facts that are given is that the number of men employed at the machine-operated mines was last year 4314, and the percentage being taken, there is the further fact that whilst a little over 12 per cent. of the total men employed in the coal mines of Illinois were thus employed, yet the output, as we have just said, was 25 per cent. of the total—a very striking contrast. A table is given of the average production of each kind of machine, which shows that they vary in output from 6239 tons to 17,784 tons. But the number of the men employed in operating the machines varies—some kinds needing 6·4 men on the average, and others up to 20·1 men each, so that the actual yield is not to be taken from the mere average only. For the whole number of machines in Illinois, there is now need for an average of 14·2 men each, which is an increase on the number in the previous year, possibly due to the variation in the types of the machines. It is to be observed that the yield of the machines was on a working that on the average was a fraction over 250 each per year; and taking the mines where machines are exclusively employed, it is found that they vary in size, one producing only 21,000 tons in the year, whilst other collieries rise in output to as high as 304,000 tons, which is produced by 206 men in 255 working days, about eighteen Harrison machines being in use. Differences in the kind of seam, the nature and working of the coal, and other variations may influence the use of machine or hand labour, but the facts that are above summarised are of interest, and may have value to those who have the oversight of coal mining in this country.

### NEW WATER SCHEME FOR EDINBURGH.

For many years an improved water supply for Edinburgh and the district has been regarded as highly essential, and if the increase in population of the capital had been anything like as rapid as in the case of Glasgow, definite steps to this end must have been taken long ago. As far back as 1871 an attempt was made to appropriate the waters of St. Mary's Loch in Selkirkshire. A strong opposition to any utilitarian tampering with a lake of such historic and poetic interest immediately arose, and speedily attained such strength that the scheme had to be abandoned; and the whole matter of water extension was allowed practically to rest. Within the last few years, however, it has been made abundantly evident that a large extra supply of water must be obtained somewhere, and without much delay. The members of the Edinburgh and District Water Trust accordingly bestirred themselves, and have now, after due deliberation, fixed upon what is called the Tweed scheme. This practically means the utilisation of the water of a Dumfriesshire tributary of the Tweed, known as the Talla-waters. The only other source of supply seriously considered was the Manor water, a stream flowing through the Manor Valley in Peeblesshire and entering the Tweed about two miles above Peebles. This was reported upon and strongly recommended in 1891 by Messrs. Hill, Gale, and Mansergh, as being ten miles nearer Edinburgh than the Talla, and as affording a remarkably pure supply. However, borings with a view to the necessary embankments showed in some places a depth of 150ft. before rock was reached. The expense and risk which such a depth of soil entailed caused the engineers to withdraw their recommendation, and finally they advised the Trustees to adopt the Talla supply, boring in the valley having proved rock at an average depth of 28ft. The Talla water rises in three head streams in Dumfriesshire, and is also fed by the Gameshope Loch. After a course of seven miles in a northerly direction it runs into the Tweed at Tweedsmuir Church. The stream will afford an abundant supply of excellent water, and the full scheme proposed by the Trustees provides for the construction of tunnels and aqueducts to convey 24 million gallons per day to the capital, a distance of thirty-six miles. Application for parliamentary powers accordingly will be made. As a first instalment it is proposed to lay pipes capable of conveying 10 millions of gallons per day. This is estimated to cost about £646,000.

### MILD STEEL FOR STRUCTURAL ENGINEERING.

Whilst, as we last week showed, Bessemer steel is gaining ground as a material for use in manufacture outside steel rails, great progress can also be recorded of Siemens-Martin steel. This, indeed, has been gaining ground in the steel race during the last few years, and it has now passed its Bessemer rival, the output of open-hearth steel in the first six months of 1894 being not less than 1,026,469 tons, while the make of Bessemer steel was only 810,392 tons. We may observe, by the way, that the combined output of the two sorts is at the rate of 3,673,722 tons per annum, or higher than any annual total ever yet registered in the history of the British steel trade. Our chief concern lies, however, with the fact that open-hearth steel has for the first time gained the ascendancy. There has, in fact, lately been a greatly increased consumption of mild steel for all kinds of bridge and roofing, gasometer, and pier, and other departments of constructive engineering, also in the machinery trades, and among the steam boiler engineers, the tube firms of the kingdom, and other large consumers. One of the drawbacks to the use of steel in these trades is still asserted by some engineers to be its increased liability to corrosion, as compared with iron, particularly when exposed to the atmosphere or in damp or wet situations. The recent reports of some of the railway companies concerning the behaviour of steel bridges erected on British lines afford further evidence in support of those who have contended that this increased corrosion does occur, and some engineers are also seriously opposed to putting steel into piers for sea and ocean work. It is in steel designed for high tensile stresses that this corrosion is said to be most rapid. This fact is being increasingly recognised by engineers in some directions as regards both home and foreign contracts, and this tendency to prefer soft steel is likely to become more marked.

### THE MIRABEAU BRIDGE.

The work of constructing a steel bridge across the Seine at Paris, between Grenelle and the Pont du Jour, is making satisfactory progress. This bridge is interesting from the fact that it is of an entirely new type, and is intended to overcome the difficulty of facilitating traffic over the river without interfering with the passage of vessels underneath. It is to be built level with the embankment on either side, and the centre of the bridge is to be 7·50 metres above the water level. Its total length is to be 170 metres, with a central span of 100 metres. In building the two piers, a great deal of trouble has been met with owing to the shifting character of the river bed at this point. The caissons employed in sinking the piers were supplied by the Compagnie de Fives-Lille, whose system has been much improved since the accident which took place some years ago at Nantes, when a workman was blown thrown through the discharge pipe. Before reaching a solid foundation of chalk, at a depth of 16·20 metres, it was necessary to dig through layers of sand and marl, and this work was made difficult by the presence of heavy flint blocks. A great quantity of this material had to be raised before the foundation could be laid. At the present moment both piers are completed, and work has been in progress during the past three months upon the superstructure on the left bank of the river. The steel used in its construction is supplied by the Anzin Works, in the Nord, and the Imphi Works, in the Nievre, and about 2500 tons of this material will be employed. It is not expected that the bridge will be finished before the middle of 1896, owing to the difficulty of employing many hands at a time. The cost of the bridge is estimated at £140,000. Designed by M. Résal, chief engineer of the Ponts et Chausées, the new bridge is not only interesting from an engineering point of view, but is likely to prove one of the most picturesque erections across the Seine.

# RAILROADING IN AMERICA.

By An English Railway Engineer.

## CARS.

In my previous article comparison of English and American practice in locomotive building was avoided as being undesirable; but when dealing with the subject of cars or rolling stock, one cannot help remarking the great difference in the two prevailing systems, and at times comparing the comforts and conveniences of the relative styles. The American car in its own country is a vastly different article to the "corridor" imitations attempted on this side of the Atlantic. and must at once be acknowledged superior in many respects; one of the greatest helps to its successful adoption in the States being, no doubt, the practical employment of one "class" only. In America, as probably many of your readers are aware, the holder of an ordinary ticket has a free run of the entire train, notwithstanding the provision of the superior accommodation of the Pullman and Wagner Company. It is also pretty generally known that the ordinary fare is about one penny per mile, or equal to our third class for accommodation in many cases equal to that given at home as first class, the additional charge for "sleepers," drawing-room cars, or limited trains, being about one farthing per mile extra.

It is often urged in this country that American cars are heavier and more costly than carriages for a given carrying capacity; but there are several points to be considered in favour of the cars which only become apparent upon closer acquaintance. For instance, in English trains the heavier carriages are usually hauled with few passengers, the first and second classes being often practically empty. With carriages, too, some may be crowded whilst others in the same train and of similar class lack passengers. In the American train all are utilised, and each car takes its fair proportion of passengers. Here lavatories are provided for first and second-class and perhaps a few favoured third-class passengers, but although there may be possibly a dozen lavatories in the train, they are only available to the occupants of twice as many compartments—unless fitted in corridor carriages—out of perhaps a total of over sixty. The lavatories, moreover, are awkwardly placed, are liable to affect the sanitary conditions of the compartments, and are rarely used when passengers of both sexes are present. Here then is a typical example of maximum weight and cost with the minimum of convenience. In the American cars seating sixty, and in some cases eighty passengers, two lavatories are provided, available for all the passengers, and being located at the ends of the car, and not under the continual notice of the passengers, more general use is made of them. Another important advantage of a continuous passage is apparent on "through" trains when a dining car is attached at meal-times and run for those times only, being detached at the first convenient stopping place. In the carriage system, on the contrary, kitchen and saloons are run continuously, and form a useless augmentation to the weight of the train during a considerable portion of the journey, and in cases where the saloon is not connected by a gangway with the other carriages, the passengers in America have not the privilege accorded them universally of changing cars after dinner has been served. Before quitting this part of the subject, I should like to say a few words on a point often urged in this country as being an advantage possessed by the carriage system over that of the cars, viz., that greater facility exists for ingress and egress by a door being provided for every ten passengers, against only one for thirty in America. This may be substantially correct in theory, but it makes no allowance for the only too familiar old lady who sometimes keeps a whole train waiting whilst she runs from one end of the platform to the other to select a suitable compartment, or for a group of passengers waiting at the wrong portion of the platform for the particular class of carriage they require. One trip on the Chicago Elevated Railway is sufficient to cause one to modify this opinion considerably. On this line the average speed attained is fifteen miles per hour from terminal to terminal, including stoppages at the rate of three per mile; while on the underground railway in London the average speed is only twelve miles per hour, including only two stops per mile, similar service engine requirements being involved in each instance. On the cars the passengers are directed by the conductors to alight at one end while newcomers enter at the other, thus preventing delay on the platforms by passengers in search for vacant seats, distribution taking place largely *en route*. There is, moreover, no alighting from or entering the train while in motion, as the conductors control the gates on the car platforms in a manner similar to that employed on the South London Railway. There are, however, exceptions to the car system, even in America. On the Brooklyn Bridge, and at Chicago during the Exhibition period on the Illinois Central Railroad, the carriage style was adopted. But in both these cases crowds had to be carried between two points only, and consequently the side doors were used to great advantage.

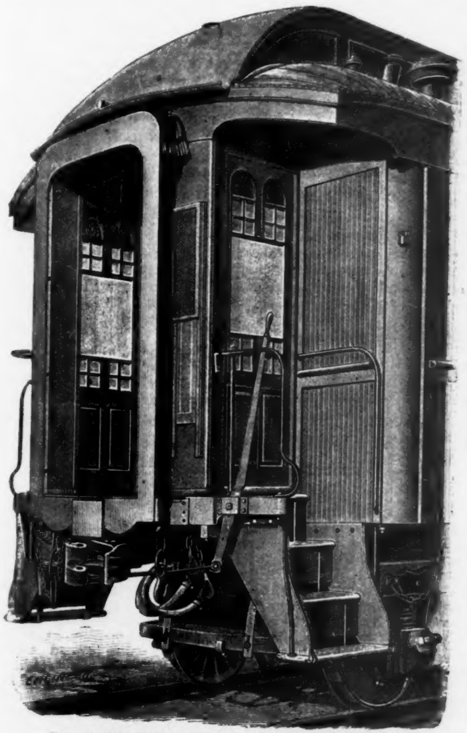

Fig. 3—GENERAL VIEW OF BARR VESTIBULE

As regards the construction of American cars, these differ from our carriages in having no separate body and underframe. The sides form the frame and approximate two girders, strongly braced and trussed, resting on trucks at either end. In modern cars the framing is of timber and iron or steel combined. The sides present a flat furface about 10ft. wide, and have no projecting handrails or steps. As there are no raised platforms at main line stations, a miniature staircase is provided at each end, leading on to the platform. The plan, Fig. 1, gives the arrangement of an ordinary day car. The seats have reversible backs, usually reversed by the conductor or train men, and locked, so that all passengers face the engine. They are comfortable, and when "reclining" chairs are used, are very easy. The seats are of braided wire, upholstered in brown or crimson plush. The windows are large, and are invariably clean, many ingenious little contrivances being employed for raising and lowering them. Each car is provided with iced water, and also glass-fronted cupboard containing a number of useful tools in case of mishap, such as an adze-saw, hammers, &c.

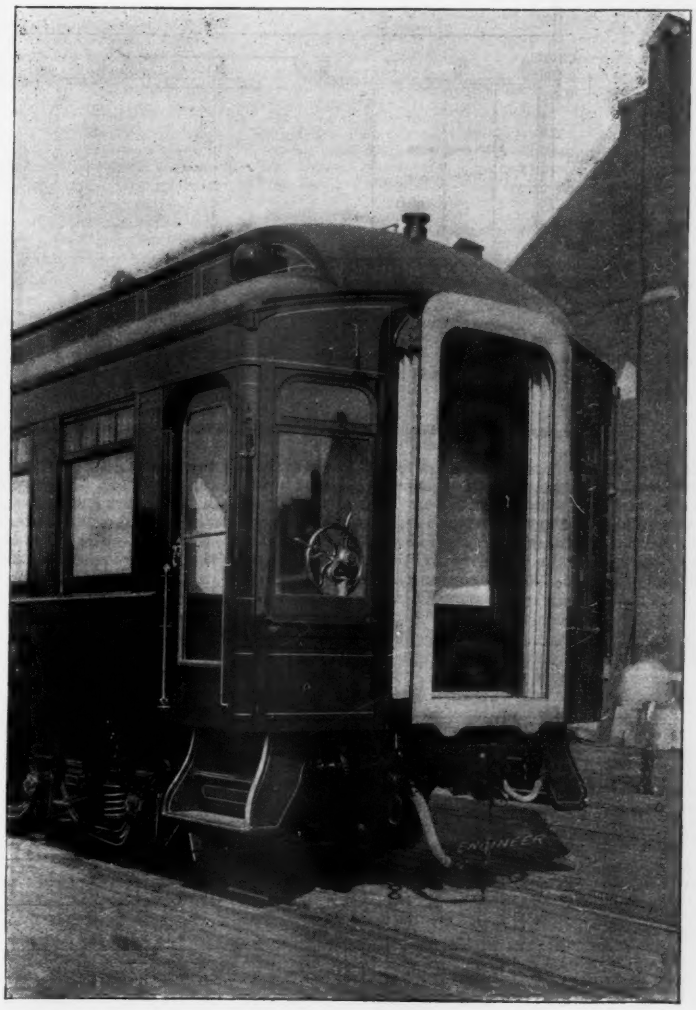

Fig. 5—VIEW OF PULLMAN CAR "MAUD"

Vestibules are rapidly becoming universal, and have received considerable attention. Apart from the convenience of affording a covered communication between the cars, doubtless a good vestibule as constructed in the States offers very considerable resistance to telescoping, and this has been recognised to such an extent that in some cases a cast steel frame is placed at the rear of the engine tender to receive the first vestibule, thereby ensuring a continuous connection throughout, and a few words describing them may prove acceptable. The "strings," bolts, and catches of the English gangway are unknown features of the American vestibule. Two vestibules can be simply "bumped" together as they couple up automatically, while one movement of a lever on the platform of the car is generally sufficient to uncouple them. The framework of the car end has provision for four buffing springs. The spindles passing through these are attached to a strong flat iron frame faced with rubber, the connection between this frame and the car body being made with a rubber bellows. The folding doors of the vestibule open on to a stairway on most cars, but as tramps have been found to make use of these for free transport, in later practice the vestibule is brought out to the full width of the car, and the steps are covered by a trap door opening upwards by means of a handle. A sketch of such an arrangement is shown in Fig. 2 herewith. In the Barr vestibule timber is used exclusively, the joints only being provided with a rubber cover. In Fig. 3 is depicted a general view of one of these vestibules, and Fig. 4 shows a plan thereof.

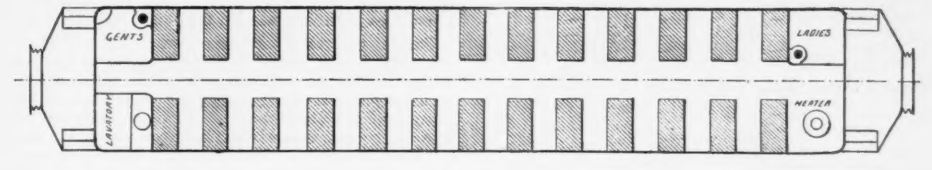

Fig. 1.

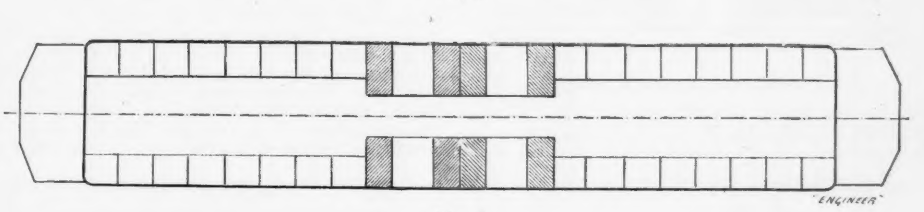

Fig 6.

A train shown by the South Pacific Railroad Company at Chicago had the Krebel vestibule. This is a connection the full width of the cars, so that the train is practically one width from end to end, with flexible joints. Pullman cars appear to be run on nearly all "through" trains; and as they are well patronised, the attendance, cuisine, and conveniences are excellent. Each car has five sections on each side, or seats for forty, and a state-room for four—some without the state-room accommodate forty-eight passengers, berths being provided for the same number. The lower berths are formed by drawing out the opposite seats—in the Pullmans all seats face each other—and the upper are pulled down from above; these when closed and occupying a slanting position have sufficient space to contain all the bedding for both upper and lower berths. A wooden panel fits in between the back of each seat and the car roof, and effectually divides the berths, whilst curtains are provided to secure privacy. Hooks are conveniently placed in each, and a net may be slung for loose apparel. At one end of the car a small smoking-room either adjoins the lavatory or forms one apartment, and at the other a ladies' dressing-room is provided. Fig. 5 shows a view of the Pullman car Maud.

Returning to the railway companies' cars, the New York Central have recently built for their famous Empire States Express some very large cars, 80ft. long and 10ft. wide, just over 9ft. inside, on six-wheeled trucks with wheels 36in. diameter. Seats are provided for eighty-four passengers, and the weight of each car is 95,400 lb.

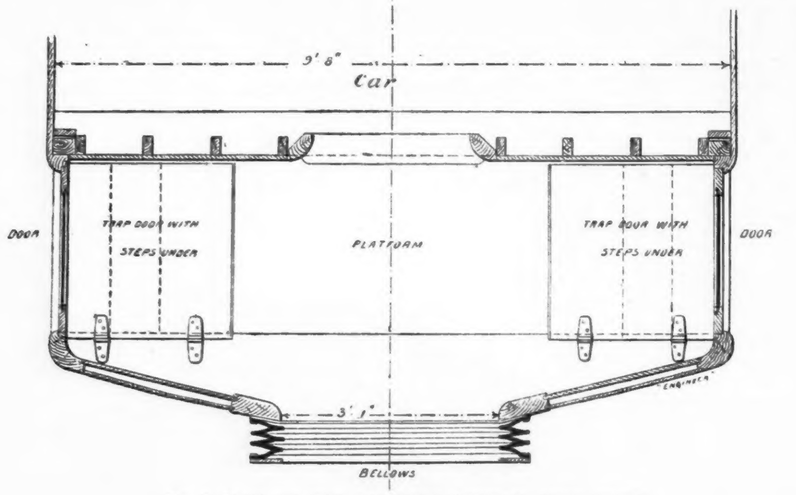

Fig. 2—PLAN OF CAR VESTIBULE SHOWING TRAP DOORS

Private cars are much used in the States, very magnificent vehicles being owned by some wealthy families, while on trains running into New York and other big cities from outlying suburbs, club cars are attached subscribed for by parties of city gentlemen resident in the district. The train exhibited by the Canadian Pacific Railway Company at Chicago was one of their standard patterns, used on the trans-continental services, and consisted of five vehicles as follows:—

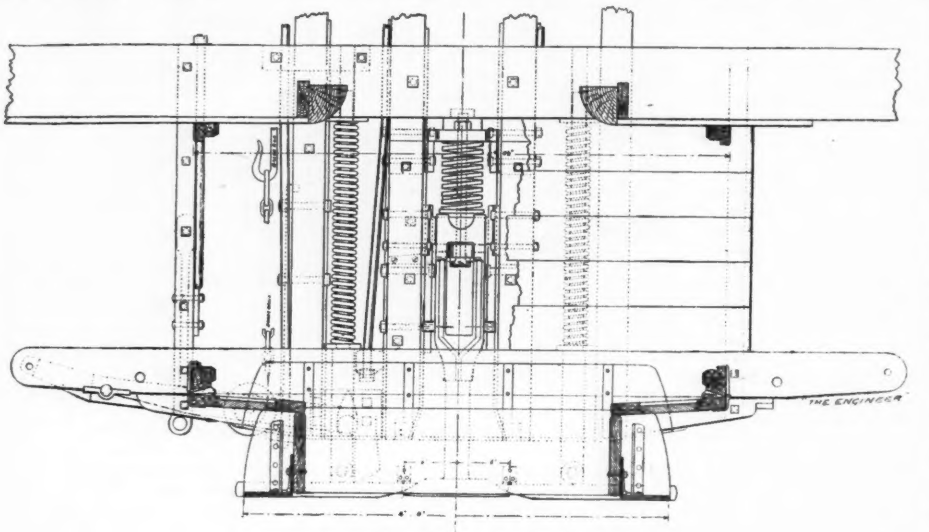

Fig. 4—PLAN OF BARR VESTIBULE

| | Length. ft. in. | Weight in pounds. | Seating capacity. Persons. |
|---|---|---|---|
| Baggage car ... ... | 63 8 | 59,600 | — |
| Second-class car ... | 64 4 | 65,500 | 64 |
| First-class car... ... | 64 4 | 65,300 | 56 |
| Dining car ... ... | 70 10 | 85,000 | 44 |
| Sleeping car ... ... | 77 2 | 94,000 | 44 |

Second-class vehicles are provided for emigrants on the Canadian and Pacific, Grand Trunk, and a few Western American railroads; but Pullmans are usually placed in the rear and dining cars at the extreme end of the trains in America. Fig. 6 represents a plan of one of the cars employed on the Chicago Elevated Railroad. It is 46ft. long, 8ft. 6in. wide, weighs 28,000 lb., has a double door at each end, and accommodates forty-eight passengers. These cars are lighted on the Pintsch system, and the trucks have wrought iron wheels. The cars employed by the Illinois Central Railroad for exhibition traffic were convertible into their standard freight cars, 35ft. long, and supported on two four-wheeled trucks. They had seats arranged transversely, with panels and windows at the sides but no doors, sliding bars only being provided across the doorways, and could be moved from either end by the conductor. Each vehicle had eight compartments or sixteen seats, and carried eighty passengers.

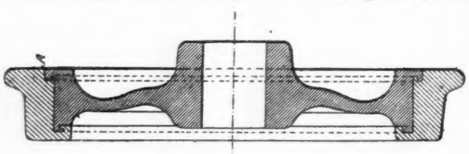

Fig. 7—SECTION OF BOIES WHEEL

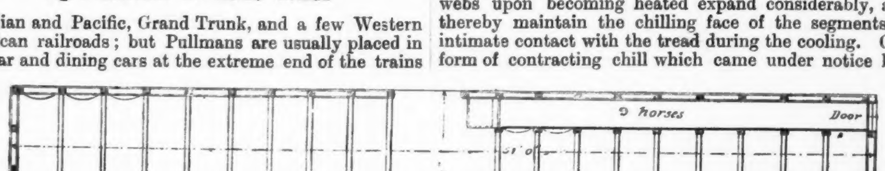

Fig 8—PLAN OF BURTON HORSE CAR FOR 18 HORSES

A type of vehicle which is coming into very general use in the States is the Harrison postal car. In this car the floor space can be utilised as required, as the tables can be raised, lowered, or detached at will. Part of the racks are simply portable, and each section, as a whole or in part, may be taken down or folded away in a very brief space of time. In the design of these vehicles special attention has been devoted to their lighting and ventilation, while the arrangement of the fittings is such that a larger number of persons can be employed in a given area than with the old-fashioned style of van.

Turning now to the running gear, it may be stated that pressed steel frames for the trucks appear to be gaining ground, while the wheels, springs, &c., employed, differ so largely that it would occupy too great a space to allow of only a brief description of all the varieties employed. The chilled cast iron wheels, however, which are largely in use, deserve a few words. These wheels are usually 33in. diameter, and are cast by some makers in contracting chills, wherein the chilling ring in contact with the tread of the wheel is made up of segmental blocks connected by thin radial webs to the outer ring or frame of the mould, which ring preserves the true cylindrical form. These thin webs upon becoming heated expand considerably, and thereby maintain the chilling face of the segments in intimate contact with the tread during the cooling. One form of contracting chill which came under notice had three surrounding rings, alternate segments of the chill surface being connected by webs to the first and second, and second and third rings alternately. Fig. 7 represents a transverse sectional elevation of the Boies wrought iron wheel, with steel tire. The retaining lip A is headed down into the groove shown after the pressed iron body is dropped into position in the tire, and to remove the tire the wheel is placed in a lathe and this ring turned out. Couplers offer an immense field for invention, and the varieties appear to be legion. They are all made to couple in the vertical plane, and have suitable arrangements for working with a link and pin if required. A defect, however, is apparent on many roads where the coupler head takes all buffing as well as draft stresses. Some companies provide their cars with cast iron buffer blocks, so that as soon as the jaws are attached these blocks come in contact.

In the description of the locomotives attention was called to the air communication means between the cars and engine in use on many of the chief trains. This comprises a small ¾in. air pipe, which runs the entire length of the train, and is charged with air under pressure from the locomotive. On the latter is placed a "signal valve," which is so constructed that a reduction of pressure in the train pipe, caused by opening cocks in any of the cars, opens a passage leading to a miniature whistle, through which air is allowed to escape, thereby giving an audible signal to the attendants.

In no country, probably, has the heating of railway cars received more attention than in the States. On some of the small roads old-fashioned stoves prevail, but on trunk roads some form of steam heater is generally used. In the Baker steam-heating system each car is rendered independent of its neighbours, a small stove being fed with coal from a hopper arrangement, and causes hot water to circulate through radiating pipes. In the Gold system, steam is conducted from the locomotive through storage heaters in the cars, charged with brine. These retain their heat for a considerable time after losing their steam supply.

In the external finish of the cars there is as great a variety as at home, the colours ranging from cream of the "ghost" train to dark blue of the Wagner cars. The Pullmans are uniformly painted a dark green and black, lined in gold, and each car is named for convenience of recognition. They are well kept, and present a fine appearance. The Pennsylvania Railroad favour a chocolate brown colour for their cars, but other roads use yellow and brown chiefly. The Canadian Pacific Railroad imitate English practice in adopting varnished wood.

Freight cars are of large size, usually running on two four-wheeled trucks, while 25,000 lb. to 30,000 lb. is a customary tare for a car of 60,000 lb. capacity. Box cars are more extensively used than in this country, but a "sheeted" truck is never seen. For mineral traffic open cars or "gondolas" are provided, whilst many roads having a large coal traffic provide hopper cars for this purpose. The Baltimore and Ohio Railroad have some unique cars, which require a few words of description. The body is made up of three intersecting cylinders, with hopper bottoms, on two four-wheeled trucks. All cars are furnished with brake blocks on each wheel. These are operated by means of a hand-wheel on the top of the car, or are brought up on a spindle 3ft. or 4ft. long in the case of platform and "gondola" cars. The brakesmen under the orders of the conductor manipulate these brakes when the train is not fitted with continuous air brakes. These men travel in the "caboose"—equivalent to the English guard's brake van—and which has a kind of conning tower or raised deck with doors opening on to the roof of the cars, suitable stairways being provided for reaching this. When approaching down grades or upon the receipt of the engineer's audible signal the "crew" of brakesmen emerge from these upper doors and run down the train on a platform arranged along the centre line of the roofs, each man braking a certain number of cars. The roofs of all freight cars are of gable pattern, not curved. For horses and cattle several car companies have special cars on hire which have suitable provision made for feeding, watering, and attending to the stock *en route*. The Burton Palace Horse Car Company provides very good equipment in this respect. The horses are placed across the car, as shown in Fig. 8, each horse being railed off from its neighbour, while a manger running along the side of the car is accessible to the men in charge by a passage between it and the car side. Special cars are also provided for fruit, meat, &c., the arrangements for refrigerating, &c., being excellent. For ballasting purposes plain platform cars are used, which can be unloaded with mechanical unloaders, resembling a snow plough drawn along the train of cars by the engine or by a winding appliance worked from it.

PUBLIC WORKS IN ALGERIA AND TUNIS.—Five miles of a line constructed by a French society for working the phosphate beds at Tebesah, a town situated on the frontiers of Algeria and Tunis, have been recently opened for traffic. At this distance from its starting point it joins up to the existing branch line, which connects Bône-Guelma with Ain-Kissah, the principal locus of the whole undertaking, although the greatest quantity of phosphate is procured at Ain-Dibah, to which place the present railway will be subsequently extended. At Mustaphah, fifteen thousand pounds are to be expended in the building of workshops and other premises attached to the Arsenal. Towards the end of last month the first line in Algeria, constructed by the company of Algerian railways, was inaugurated, and the first train run between El-Affroun and Marengo. Since then the traffic in both passengers and goods has been constantly and regularly maintained. It is stated that notwithstanding the advanced condition of the marine works, the new town at Bizerta is not provided with any water supply, nor with any buildings of the character absolutely indispensable to the welfare of the place. The sources of the water supply of Ain-Bourras sink away into the sand. Public edifices, such as schools, post-office, law courts, town hall and others, promised since last April, are still in the clouds. Great delay attends the sale of the lands belonging to the Harbour Company, and the period of stagnation presses severely upon all branches of local trade and commerce, without taking into consideration that the present state of uncertainty and indicision may exercise a very injurious effect upon the future prosperity of the port. It is satisfactory to be informed that the inauguration of the Bizerta-Djedeidah railway will probably take place at the end of the present month although that event in itself is a reason for hurrying up with the water supply.

# LETTERS TO THE EDITOR.

*(We do not hold ourselves responsible for the opinions of our correspondents.)*

## THE PORT OF MANCHESTER.

Sir,—In your issue of the 12th instant you quote from "Fair Play" a series of questions which, you say, Baltic men and others have been led to ask on consideration of circulars issued by the Ship Canal Company. The tone of these questions, and the evidently hostile spirit in which they are propounded, might lead one unacquainted with the subject to suppose that they were indeed very awkward posers for the supporters of the canal, and that it would be impossible to answer them save in the damaging sense which is suggested by the questions. Lest any of your readers should be thus deceived, allow me very briefly to deal with the "series" seriatim, with the object also of imparting to "Baltic men and others" the information of which they stand in need.

First, then, with regard to the saving to importers to Manchester direct, as compared with *viâ* Liverpool. It is evident that in his remarks the questioner has in mind the cargoes of cotton which arrived in the Manchester Docks in the early part of the year. I may remark that the canal was not open for traffic last year, so I am at a loss to understand what is meant by "the freight last year."

It is quite true that on the cotton cargoes imported in January and February last there was not a very great saving as compared with cotton brought from Liverpool, owing principally to the railway companies not having then fixed a shipping rate between the Manchester Docks and inland towns, charging inland rate on the imported cotton, and owing partly to the backward state of the arrangements for storing and handling the cotton. Now, however, these initial difficulties have been overcome, and a through rate has been fixed inclusive of all charges from the ship's hold to the mill, which shows a considerable saving on cotton brought to Manchester direct, as compared with cotton ex warehouse at Liverpool, in the case of over 90 per cent. of the Lancashire cotton mills. As a further proof that there are substantial advantages in importing cotton to Manchester direct, comes the fact that at the present moment steamers are loading cotton in America and the Levant for this port, and this in spite of the alleged failure of the experiment last season. As to goods other than cotton, one instance will suffice. The Wholesale Co-operative Society, which has invested a large sum in the undertaking, stated within a few months of its opening that even though it was never to see a penny of their investment back again they would be no losers, in view of the amount they had saved by importing direct to Manchester.

Secondly, as to warehousing. The impression that Manchester is unable to warehouse cotton and other cargoes is entirely erroneous. The Canal Company has ample warehouse accommodation within easy reach of the docks, to which cargoes are easily and cheaply conveyed by barge from the ship's side, in addition to the extensive storehouses owned by private warehousemen. These are equipped with every facility for handling goods in bulk.

Thirdly, "What cargoes which usually come in bulk has Manchester a market for? Timber, grain, and cotton perhaps." Yes, timber, grain, and cotton; and, to name only some of those which have already arrived in full cargoes in the few months during which the canal has been open: Iron pyrites, ore, pig iron, boiler-plates, stone, china clay, dyewoods, wood pulp, paper, oil, green fruit, dried fruit, and fish. An excellent wholesale market, second to none in the country, exists in the city for cattle, dead meat, provisions, &c.; and Manchester does expect, and the experience of the past months proves it a reasonable hope, that general cargoes will come freely to her docks for distribution amongst the enormous population of seven millions of which she is the natural centre and nearest seaport, and to serve which she is already provided with a system of railway and canal communication with all parts of the kingdom which will bear comparison with that of London itself.

Fourthly, as to outward business: Manchester can find coal cargoes for an unlimited number of vessels, being the nearest shipping port for the collieries of Lancashire, Yorkshire, and Derbyshire; and coal can be shipped either in the Manchester Docks or at the coaling basin at Partington more cheaply than either at Liverpool or Garston. There are already a number of colliers trading regularly between the canal and English, Scotch, and Irish ports, besides numerous vessels which bring timber and other cargoes, and take out coal. Salt cargoes can also be readily obtained in the canal, one vessel having taken out 4000 tons of this mineral to Calcutta from Saltport, whilst as an instance of bulk cargoes of another kind, one of the continental lines running from Manchester has at present a contract for some 10,000 tons of carbon refuse.

Manchester, one of the greatest engineering centres in the world, can find plenty of heavy cargo for the bottom of ships' holds, and can fill them up with press-packed bales of cotton goods, &c., the most sought after and profitable cargo which shipowners can obtain.

It has been characteristic of the two cities during the past decade, that whilst Liverpool has been bragging and scoffing, and showing to her own satisfaction the utter impossibility of making a ship canal from Manchester to the sea, her elder sister has quietly gone to work and proved to the world that it could be done, by doing it, *solvitur ambulando*. Now Liverpool, trying to forget all the foolish things said about engineering impossibilities, still talks in a complacent way about the inevitable failure of Manchester's efforts to create a traffic. The latter, however, is less concerned to notice such windy verbosities than to disprove them by results, and can already point, after nine months' work, to established regular lines of steamers to British, European, Asiatic, African, and American ports, whose sailings aggregate over 100 per month, increases being announced nearly every week, and this without taking into consideration the large number of specially chartered vessels which enter the canal weekly.

T. M. Y.

Manchester, October 16th.

## THE THEORY OF THE STEAM ENGINE.

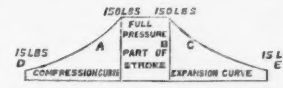
Sir,—It would be waste of time to discuss thermodynamics with a gentleman who holds that there is no difference between a permanent gas and steam, so I take leave of Mr. Cherry.

It is worth while to state more clearly than is usually done, the reasons why so much is lost in the making of the working fluid, steam. Dr. Lodge, I think, has even said that there is no loss at all. To settle questions of this kind by algebraical formulæ is only to mislead. A numerical example goes straight to the root of the matter. I shall take one pound of steam at 148 lb. absolute pressure, and consider the work which it would do with expansion between two limiting temperatures. Mrs. Glass told us long since that, before you can cook a hare you must catch it; in the same way, before you can expand steam you must make it. Let us see what the manufacture of one pound of this kind of steam involves. I will assume that we make it from feed-water at 100 deg.; then we must supply 1122 units, representing 866,184 foot-pounds. The steam is caused to work a piston loaded to 148 lb. on the square inch. The piston has 144 square inches of area, and 1 lb. of 148 lb. steam occupies precisely 3 cubic feet, consequently the piston 1 square foot in area must rise 3ft., and 150 × 144 × 3 = 64,800 foot-pounds. That is to say, we get less than $\frac{1}{13}$ of the whole heat expended in making the steam returned.

In my last letter I showed that when the steam made under these conditions was supposed to expand down to 15 lb. on the square inch, we got back about 21 per cent. of all the heat expended in producing the steam. This, of course, includes the $\frac{1}{13}$ mentioned above, and we shall then have left about ⅘ of a pound of steam, and ⅕ of a pound of hot water, the two together containing the rest of the heat, and this is to all intents and purposes thrown away in the condenser. It is the enormous quantity of heat expended in converting water into steam that is the main source of loss in the steam engine.

I do not know what the latent heat of air is. I do not suppose that any one does, but I imagine it must be pretty high, because the volume of a vapour or a gas depends largely on the latent heat. Thus the steam of ether is small in volume as compared with that of water, but the latent heat of ether vapour is less than half that of water. Whatever it is, it is supplied by Nature ready to our hands. The weight of the working fluid in a gas engine remains the same throughout a stroke; it diminishes as the stroke proceeds in a steam engine.

Two points occur to me here as claiming further elucidation. A correspondent of The Engineer whose name I forget, raised a question a year or more ago about the work done during the making of steam. He was not very clear, but I think I know what he meant. His idea was that as steam falls in pressure by expansion, giving out work, so it must rise in pressure as it is made in a reverse curve, and the work expended by the heat in compressing it ought to be all got out during expansion. Thus, then, we should have a diagram like this.



The area of A should be identical with that of C, and the full pressure part speaks for itself. Now, it seems to me that this result could only be got by starting with boiling water at D, and say 15 lb. pressure, and ending with E 15 lb. and boiling water. How this could be worked out in practice I do not quite see, nor does it matter. The only point I want to raise is this:—Would such a mode of working possess any advantage? And what is much more interesting, supposing that we generate steam under a pressure of 150 lb., what occurs to the feed-water before it changes into steam? Its temperature runs up. I suppose that as it runs up some force of repulsion is developed among the molecules. Could this force be graphically depicted by a curve?

The other question of interest is this:—Supposing it was possible to generate a pound of steam at 150 lb. pressure, without doing external work. Less heat would be required than is needed to generate it in the normal way. Is this taken account of in the normal steam tables? Do the figures in the normal steam tables give the quantity of heat which can be got back by condensing a pound of steam, or the quantity expended in producing it? Obviously, the two quantities cannot be identical.

October 15th. Maurice Cross.

Sir,—Writers on thermodynamics are much to blame for misrepresenting the teaching of Carnot. Either through ignorance or through carelessness, they lead their readers to understand that Carnot intended his "reversible cycle" as one to be aimed at and approximated to in actual heat engines. That he did not so intend is made quite clear by the following extracts from his work:—"The question has often been raised whether the motive power of heat is unbounded, whether the possible improvements in steam engines have an assignable limit—a limit which the nature of things will not allow to be passed by any means whatever; or whether, on the contrary, these improvements may be carried on indefinitely. . . The phenomenon of the production of motion by heat has not been considered from a sufficiently general point of view. We have considered it only in machines the nature and mode of action of which have not allowed us to take in the whole extent of application of which it is susceptible. In such machines the phenomenon is, in a way, incomplete. It becomes difficult to recognise its principles and study its laws.

"In order to consider in the most general way the principle of the production of motion by heat, it must be considered independently of any mechanism or any particular agent. It is necessary to establish principles applicable not only to steam engines, but to all imaginable heat engines, whatever the working substance, and whatever the method by which it is operated.

"Machines which do not receive their motion from heat, those which have for a motor the force of men or of animals, waterfall, an air current, &c., can be studied even to their smallest details by the mechanical theory. All cases are foreseen, all imaginable movements are referred to these general principles, firmly established, and applicable under all circumstances. This is the character of the complete theory. A similar theory is evidently needed for heat engines. We shall have it only when the laws of physics shall be extended enough, generalised enough, to make known beforehand all the effects of heat acting in a determined manner on any body."

This states quite plainly, that what Carnot proposed to do was to find out the theoretical principles of thermodynamics, not their practical application to actual heat engines. His cycle of operations he uses as a new mathematical mode of investigation. That he never could have intended it as a model for the actual working of heat engines will be made quite clear from the fact that the operations of no actual heat engine can possibly be subject to the following conditions assumed in Carnot's cycle:—(1) The working body must, at every instant, have the same temperature throughout all its parts. (2) The working body must, at every instant, have the same pressure throughout all its parts. (3) The transformations through which the working body passes must take place so slowly, that the densities of all its parts may, at any instant, be the same as they would be if the temperatures and pressures of the parts at that instant were constant. (4) The transformations must take place so slowly, the visible kinetic energy of the working body be so small as to be negligible.

These are quotations from page 26 of my treatise. It will therefore be evident that the efficiency $\frac{T - t}{T}$ of Carnot's ideal heat engine cannot be attained to, nor even closely approximated to, by any actual heat engine unless it be permitted to work so slowly as to waste time of much more value than the heat we are attempting to economise.

With regard to the superheating of steam by free expansion, Rankine—"Steam Engine," section 253—says that it has been proved experimentally by Mr. C. W. Siemens.

Glasgow, October 13th. Peter Alexander.

## GOVERNING ELECTRIC LIGHT ENGINES.

Sir,—I do not know whether there are any electric light engines fitted with the Proell or other single-valve automatic trip-expansion apparatus of like construction, but if there are, I fancy I can account for some of the difficulties of governing likely to be encountered in their use. There is a peculiar feature in the action of these apparatus that is never mentioned in the published descriptions of them, and that is, that for a certain period of the stroke, these apparatus exercise no control over the engine, and "hunting" of the governor is the only feature that makes regulation of any sort possible.

I am not aware whether this peculiarity has been pointed out previously or not, but it will be easily understood from the following:—Suppose the apparatus in its mid position, and that tripping takes places there. Then at the same instant the active trip edges clear each other, the idle trip edges will line with each other, and it is only a question of condition of the edges how far the apparatus will have passed its mid position before the falling valve will be arrested by the idle edges, and only allowed to close when these edges have travelled sufficiently far in that direction. If the edges are sharp and in good condition a movement past mid position of the apparatus equivalent to 3 or 4 per cent. of the stroke may be the position at which, when tripping takes place, the falling valve will be arrested by the idle edges, and prevented from closing until the period determined by the excentric motion. If, on the other hand, the edges are somewhat blunted, 6 to 8 per cent. may represent the movement past mid position at which the valve is arrested, but the period of closing will be as before. When tripping occurs later than the period of closing by the excentric motion, the engine is again under control.

The extent of this lapse in the control of the engine may be ascertained thus:—The angle of the crank from the commencement of the stroke until the trip apparatus is in mid position is equal to the negative advance angle, and the angle of the crank from the commencement of the stroke at which the valve, when arrested, closes by the excentric motion in that direction, is equal to twice the negative advance angle plus the lead angle. The apparatus are generally stated to have an automatic range of cut-off from 0 to ¾ of the stroke, which allowing 6 per cent. for clearance of trip edges, is equal to 38 deg. negative advance angle. The apparatus is therefore in its mid position when 10 per cent. of the stroke is completed, and allowing 6 per cent. for condition of edges, &c., any trip that takes place at 16 per cent. of the stroke will not be followed by a cut-off until (2 × 38 + 6) = 43 per cent. of the stroke is completed, that being the position at which the valve closes by the excentric motion. Nor will any trip between 16 per cent. and 43 per cent. of the stroke be followed by any other cut-off but 43 per cent. of the stroke, as between these positions the valve will be arrested at every trip. Instead, therefore, of the range of automatic cut-off being from 0 to ¾ of the stroke, it is only from 0 per cent. to 16 per cent. and from 43 per cent. to 75 per cent., and the "hunting" of the governor is relied on to cross the interval between 16 per cent. and 43 per cent., during which no control can be exercised.

If the range of cut-off were limited to 55 per cent., and with the allowance of 6 per cent. for condition of edges, the negative advance angle for this range would be such that there would be no break in the control throughout; but 35 per cent. of an automatic range may be obtained from a positive advance excentric, and it is questionable whether the extra 20 per cent. is worth an independent negative advance excentric, when the positive advance slide valve excentric is ready at hand for the lesser range.

240, Wallgate, Wigan. Jas. Dunlop.
October 13th.

Sir,—I have read with much interest what has appeared in The Engineer on this subject. The letter of Mr. Robinson may be taken as an example of the difference in method of treatment which exists between the engine builder and the electric light engineer. Mr. Robinson evidently does not grasp what it is we want. A heavy fly-wheel may help us in some respects, but in others it is just the thing we do not want; everything depends on the system of working employed.

I know by experience that the average engine builder goes on the "one man one vote" system, to have one engine drive one dynamo and work one circuit, and provision must be made for variations in the demand for current in that circuit. I devoutly wish that this was the case. Without going into minute details, I may give Mr. Robinson and others of your readers a comparatively elementary case, and ask how they would deal with it. There are two engines and two dynamos; each will indicate, say, 600-horse power. During the daytime one of these supplies current, and works up to 250 or 300-horse power; as the night comes on more and more load is put on, until the power reaches 600-horse power. Then the second engine is started, and its dynamo has to send current into the same main. Obviously it must run at such a speed that the voltage shall be the same in both. At the proper moment the switch is thrown over, and both engines are now doing the work that a moment before was done by one. But the total work wanted from the two is for the time only 600-horse power, not 1200. What does Mr. Robinson suppose a governor has to do then? How would the heavy fly-wheel help?

Messrs. Robey and Co. are nearer the solution of the difficulty than any other of your correspondents, but it is easy to see that they have not quite got it. The use of current to regulate a throttle valve has been tried over and over again, and it has never yet achieved permanent success. I think the best chance lies in combining an electro-magnet with a governor of the Pitcher type, using the magnet, in fact, to hurry up the governor, and also to establish a definite relation between the engine, the current, and the number of revolutions. The centrifugal governor takes no account of current, but only of revolutions. The current ought to have a voice in the matter.

I may say incidentally that all your correspondents talk of throttle valves. What about governing Corliss engines? There is something peculiar about their action which I do not quite understand. There seems to be a considerable range of speed at certain ratios of expansion when they do not govern at all. Thus a governor will do very well at ranges between no admission and 14 or 15 per cent. and within 50 and 63 per cent., and very badly indeed at other ranges. I should like to have this point cleared up. It has something to do with the trip faces, I fancy.

Bolton, October 16th. P. K.

## OIL-FIRED STEAMERS FOR HARBOUR USE.

Sir,—I have read with much interest your leader which appeared in your issue of 21st ultimo in relation to "Oil-fired Steamers for Harbour Use;" the only objection I take to it is that it stops short at the advantages and utility to "steamers for harbour use," and therefore I now propose to demonstrate that this is only a very restricted sphere for oil fuel, inasmuch as all that you have written is equally applicable to ocean-going steamers.

I proceed to analyse the possible objections which "vested interests" may see in this assertion. Firstly, it will be asked by those in opposition, Can the oil fuel be obtained in sufficient and easily procurable supplies at the respective ports of call? My answer is emphatically "yes;" for from the moment that a regular demand for oil fuel manifests itself contractors for delivering the same at any desired point or points can be found in the same manner as is done with coal now. Anybody who has studied the question of the possibilities of the oil production of the world can determine for himself that eventually the supply would be equal to any demand the markets might make on it, subject only to ordinary trade fluctuations in price. It is a well-known fact that large tracts of country in various parts of the world are known to be oil bearing, and only require the stimulus of a commercial demand to enable these new fields to come into actual working. Secondly, it has been widely asserted that, so far, no system of working has been discovered which would bear the daily wear and tear of a long ocean trip; ample proof to the contrary is available.

Now I come to the question — Will the underwriters of the hull or the cargo raise any difficulties, or in any manner penalise the oil system as against coal?

From all the inquiries I have made from responsible quarters, I can with safety answer this in the negative. All that will be required is that the oil system of firing be carried out under proper rules and regulations, which will be formulated by the recognised insurance authorities to meet the case; and, from what I have ascertained, such would in no way be drawn up so as to make the adoption prohibitive or in any way disadvantageous in competition with coal. Doubtless, on the other hand, at the first set-off, merchants' minds would have to be set at rest as to a possible prejudice to their cargoes from the new system of firing, and this factor, no doubt, weighs heavily with the shipowner, who otherwise has an open mind on the subject.

I am confident that the prejudice existing on this score would very soon vanish by practical experience, inasmuch as it has already on various occasions been demonstrated that it has no existence in fact. For example, it is well known to all concerned in the oil trade that oil tank steamers have carried cargo—such as sago and other fine freight—in their empty tanks without any damage or injury which would be ascribed to their mode of carriage.

The comfort of all on board, be they passengers or crew, would under all conditions be greatly enhanced. As a professional man, I can only hope that some far-seeing commercial mind will grasp and vitalise what appears to me so patent as this superseding of coal by oil fuel in ocean steamers and in other important trading and industrial enterprises. That it must come about, notwithstanding all opposition, I feel sure.

EDWIN N. HENWOOD, N.A.

22, Great St. Helen's, London,
October 13th.

### LABOUR AND LUXURIES.

SIR,—I was much amused by the letter of your correspondent, "X. Y.," published in your issue of the 12th inst. In it he defines the science of political economy, a science intimately connected with human affairs, as "knowing nothing of morals."

Such a science may be interesting as a curiosity, but it can be of no practical value. It is as if an engineer were to propound a theory of boiler furnaces which took no account of the draught. Further, I would ask "X. Y." to consider whether it is employment that men desire, or whether it is food, clothing, and the means of developing their minds and bodies to the full. I think he will agree with me that man cannot live by work alone. In fact, all the tendency of recent improvements in machinery is to reduce the amount of human labour required by the world. If, then, food, clothing, and the development of mind and body is what men want, any labour spent otherwise, which might have been employed in obtaining these, is a dead loss to the community.

Again, as to low wages. Let us, for example, take a collier and a distributor of coal, each of whom receives one-half of the price of the coal paid by the consumer. Now, suppose that the collier's wages are reduced by 50 per cent., the cost of the coal to the consumer, and therefore, arguing on the lines of "X. Y.," the cost of all commodities to the collier will only be reduced by 25 per cent. Thus he is very distinctly a loser.

Finally, shall I be considered rude if I recommend to "X. Y." a careful study of the writings of Carlyle, Ruskin, and Solomon before he writes again on "Labour and Luxuries." HIRN.

Owens College, October 15th.

SIR,—It is difficult to reconcile "X. L.'s" views with the writings of the authorities he names. Perhaps none of them use the actual noun *benefactor;* but in treating of a similar question, Adam Smith uses the word *generous*. Ricardo speaks of sympathy with, and desire to benefit the working man, and Mill speaks of doing good to the labouring classes. Indeed, the Woolwich labourer might gather powerful arguments from Mill.

"For practical purposes, political economy is inseparably intertwined with many other branches of social philosophy. Except on matters of mere detail, there are perhaps no practical questions—even among those which approach nearest to the character of purely economical questions—which admit of being decided on economical premises alone. And it is because Adam Smith never loses sight of this truth—." But I need not extract the rest of Mill's praise of his predecessor from his eloquent preface, for no more is needed to show that both regarded political economy as the study of man's well-being. So far nothing has been advanced to show that the labourer's economics were hazy, however shaky he may have been as to matters of fact. W. A. S. B.

October 16th.

### ALUMINIUM TORPEDO BOATS.

SIR,—Referring to the letter which appeared in your last issue regarding the aluminium torpedo boat, lately constructed by us for the French Government, in which a comparison is made with a similar type of boat also built by us—described in your issue of December 11th, 1891—we have the pleasure to explain what seems to be a discrepancy in the results. The speed obtained in the earlier-constructed boat was 20·03 knots, being the mean of six runs on the measured mile; and the trial was conducted in light trim, while in the case of the French boat a load of three tons was carried, and the trial for speed was the mean obtained during a continuous run of two hours, consequently the earlier boat was tested under much more favourable conditions—partly due to the shorter duration of the trial, and partly to the lesser weight carried. If the aluminium boat had been tested in the same manner as the earlier boat, as regards the load carried and duration of trial, there would have been no difficulty in obtaining 22 knots. The gain of 3½ knots—referred to in your recent description—has reference to a comparison between the latest boats of the same class built by us for the British Government, which were furnished with locomotive boilers. These boats obtained 17 knots, under the same conditions of load and duration of trial as the aluminium boat; therefore, in comparing the two, the statement is quite correct that the aluminium boat is the faster to the extent of 3½ knots. This gain is due partly to the adoption of aluminium, partly to the superiority of the water-tube over the locomotive boiler, and partly to the correct balancing of the machinery. We trust this explanation will make the facts clear to your readers.

Poplar, October 13th. YARROW AND CO.

### MODERN LOCOMOTIVES IN THE RECENT COLLISION.

SIR,—The statistics given as to weight of train in the recent collision seem to show, either that the six-wheeled rolling stock still used by the East Coast lines run with more friction than the bogie carriages as running all over the Great Western and Midland railways, or that the ponderous compound locomotives recently built by the North-Eastern Railway cannot haul a train of only fourteen coaches over easy gradients without a pilot engine. The approximate weight of train was as follows:—

| | Tons. | |
|---|---|---|
| 1st engine .. .. .. .. .. .. | 40 | 162 t., engines and tenders. |
| Tender .. .. .. .. .. .. .. | 35 | |
| 2nd engine .. .. .. .. .. .. | 52 | |
| Tender .. .. .. .. .. .. .. | 42 | |
| 13 6-wheelers .. .. .. .. .. | 169 | 194 t. train. |
| 1 Pullman .. .. .. .. .. .. | 25 | |
| Total weight .. .. .. .. | 356 | |

There is no doubt whatever that one of Mr. Macdonnel's engines, weighing 39 tons, and tender with pick-up, weighing 15 tons, altogether weighing 54 tons—equal to only 28 per cent. of carriage weight instead of 84 per cent. as above—would easily have hauled the train in question.

I venture to think that some information from railway men as to the above question would be of interest, not only to shareholders, who are annually met with the tale that increased working expenses have more than swallowed up all profits from increased traffic, but also to that constantly increasing class of travellers who, like your humble correspondent, follow eagerly all that appears in the press as to railway developments, &c. F. BOWLES.

34, Queen-street, London, E.C., October 15th.

### FRENCH CRUISERS.

SIR,—The French cruisers you illustrate excel British cruisers of the same displacement in armament and armour. Surely there is something *per contra*; is it such as a naval officer would prefer to the heavier guns? Also, I note, comparing your notices of the Antwerp Exhibition with that of the late sea fight, that the Japanese had at least three very heavy guns. I presume that they made worse practice than the Royal Sovereign did the other day. W. H. E. B.

October 16th.

## THE IPSWICH SEWERS AND ELECTROLYTIC SANITATION.

AT the meeting of the Ipswich Town Council, held on the 10th inst., the Sewerage Committee, in the course of a lengthy report, remarked that to lessen the danger of the escape of deleterious gases from the sewers, they had been obliged to pursue a policy of closing the old sewer gratings, and erecting at considerable expense ventilating shafts and columns. A report presented on the 1st of March last by the Borough Surveyor showed that the sum provided for flushing and ventilating the sewers, by a loan raised in October, 1889, was exhausted, and that in all £963 had been spent. The surveyor considered that it would still require some 200 or 300 shafts and columns to deal with those yet unenclosed, at an expenditure of about £1000. Having these facts before them, the Committee deemed it desirable to make a trial of the Hermite process. The drain selected for the trial was the old sewer discharging itself by the Great Eastern Railway Company's bridge over the river approaching the main station, and running from the Cattle Market. This sewer has connected with it twenty-nine water-closets, and it also receives the drainage of a number of houses, the drainage and washing of the Cattle Market, a slaughter-house, and a malting and brewer's store, besides the condensing water of the Grey Friars'-road Foundry and the Mineral Water Co.'s Works. At various times samples were taken, and on each occasion a distinct improvement in the condition of the sewer was traceable. On the 6th of September it was deemed unnecessary to continue the experiment further, the whole of the drain having been purged of offensive odour and disinfected. As a result of the experiments, the Committee were able to state:—(1) That the fluid known as electrolysed sea water has proved itself to be a most valuable agency for the disinfection and deodorisation of sewage; and (2) that it could be produced at a smaller cost than any other disinfectant or deodoriser.

It was computed that the average daily dry weather flow of sewage for the borough amounted to about one million and a-half gallons, and it was estimated that it would be necessary, in order to deodorise this quantity of sewage, to electrolyse about 23,000 gallons of sea water to the strength of 2·25 grammes of chlorine = 35 grains of chlorine per gallon. This quantity would, in fact, suffice to deal with a population and its manufactories of 57,000 inhabitants at the rate of 1 gramme of chlorine = 15·5 grains per head of the population per twenty-four hours; but the population of the borough using the sewer was only estimated to be some 45,000, showing a large excess of electrolysed sea water to the actual head of population. The committee were of opinion that the electrolysed sea water should be allowed to fall into the main sewers, at all events for a few months, at different points along the line by means of pipes which can be laid within the sewer itself. It was fully to be expected that after a short period had elapsed, say six months, the power of the present accumulations in the sewers would have become so paralysed, if not sterilised in regard to their germ, and consequently gas-producing power, that the chlorine of the solution would travel greater distances, and in time it might be unnecessary to have more than one or two points of discharge into the sewer. It was believed that in the adoption of this process and its proper application, considerable sums would be saved which were at present expended on disinfection in other forms, and that the necessity for any further expenditure on the erection of ventilating columns or shafts would be entirely removed, and that the cost of water for flushing by lessened consumption would be very largely diminished.

The committee anticipate that the final question of dealing with the solid matter at the outfall would be very considerably assisted by the adoption of this process. It was believed that not only will disagreeable odours not be traceable at the outfall tanks and works, but that, on the contrary, chlorine would be found to be present there, and that all discharges into the river at the outfall will be absolutely inodorous within a reasonable period. The question of dealing with the solid matter had not escaped the committee's attention, and suitable screens are now in course of erection to intercept it at the outfall. From experiments which had been made it had been proved that the animal life in salt water could not be affected by the discharge into it of electrolysed sea water.

The committee reported that the total cost of the plant for Hermite disinfection would be £2000, the annual expenditure would be £443, with an annual saving under other headings of £147, making the net annual expenditure £296. Mr. Napier presented a lengthy report, giving as his conclusions:—(1) That sewage is instantly deodorised when mixed with a sufficient quantity of Hermite electrolysed solution. (2) That the decomposition of the sewage is retarded by the said mixture for a length of time, depending upon the strength and quantity of solution added, and that during this time no offensive smell is given off. (3) That if this solution, giving 40 grammes of active chlorine per minute, is discharged into the main and various arterial sewers, the offensive smells at present escaping from the manholes will be prevented, and the sewage made sterile—as far as consumption goes—for several days, sufficient for it to get well out to sea before becoming offensive. (4) That if the proposed installation produces more active chlorine than is required to oxidise the sewage, a portion of the excess chlorine will be in the form of gas, and, escaping into the air, will form an aërial disinfectant, and where sewers and drains are not properly trapped, instead of offensive sewer gas going into houses, there will be this chlorous gas acting as a disinfectant. (5) That of the processes for treating sewage that I know of, all do so at the outfalls, the object being to utilise the precipitates from the sewage, or to keep, say, a river free from pollution. A process may be adopted at an outfall for precipitating objectionable matter, or for preventing pollution, but no benefit from that will be derived by the town; but with this Hermite process the solution is distributed in the arterial sewers, the disinfection takes place there, and the sewage rendered inoffensive on its passage through the town, and is kept so for a number of days, sufficient for it to get through the whole system of sewers into the Orwell. I am of opinion that if this process is adopted, and a sufficient quantity of solution manufactured, Ipswich will benefit greatly, because by having the drains and sewers disinfected, and a flow of deodorised—perhaps sterilised—sewage through the town, the health of the inhabitants will be considerably improved.

Alderman E. R. Turner moved the adoption of the report, which he said he did with very great pleasure and satisfaction. They had had a full report, he said, from the surveyor as to other systems, but none of them were thought so applicable to the town as the Hermite process.

Mr. Goddard was surprised that a matter which had previously provoked so much difference of opinion should have provoked so little discussion that morning. He supposed that the Council had come to the conclusion that the Sewerage Committee had thoroughly investigated the matter, and placed confidence in their report. As to the cost, the previous information before the Council was that a capital expenditure would be required of from £8000 to £9000, and an annual expenditure of £1200, and the cost of the Hermite process was very considerably less. This process was said to be a speculation, and it was to a certain degree a speculation, but one which had been as highly tried as any system could be tried. First of all, it had been tried experimentally by many experts, and there were sheafs of information by those experts. As a means of dealing with sewage, he believed this process compared most advantageously with anything else that had ever been suggested. He should be very sorry to lead anyone to expect that if they adopted this process there would never be any unpleasant smell from the river, for he believed that in a river so full of weeds as theirs was this was impossible. He thought this process had this great advantage over all other processes he had looked into, namely, that of being a liquid process. Only a small labour would be involved in removing what was caught on the screens at the outfall. Besides dealing with the main sewer, the process would give the advantage of providing the borough with a powerful disinfectant which they could, at a small cost and very little trouble, convey to any part of the town. The resolution was adopted.—*East Anglian Daily Times.*

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

A NEW application of steel in this district is just now being made by Messrs. Lysaght Limited, of Wolverhampton. The step they have taken is considered hereabouts one of great importance, as signifying the successful attempts which are being made to adapt steel to purposes which have hitherto been carried out by the utilisation of iron. For some time past it has been an open secret that a firm who are one of the largest galvanised sheet producers in the Midlands have been experimenting with the newer metal, with the result that in the future they will most probably entirely abandon the use of iron for galvanised sheet manufacture. To provide for the new departure, one of the finest steel rolling plants to be found in the country has been laid down. It is found that greater economy is secured by the lower cost of the steel as compared with iron, and the lessened quantity of spelter absorbed on account of the closer grain and extra smoothness of surface. Whether or not other galvanised iron concerns will generally follow the example which has been set them by Messrs. Lysaght remains to be seen. Certain it is, however, that ironmasters recognise the increased prominence with which steel is now coming to the front, and to keep abreast of the times it is not unlikely that they will consider it desirable to early alter their present mode of production.

Business is unaltered on the week at last week's prices. The only new fact to communicate is, that preparations are being made to restart some of the blast furnaces at the Corngreaves Ironworks almost immediately.

An electrical engineering undertaking that has cost between £45,000 and £50,000 has been opened at Worcester. This is the new electric lighting works which have been erected by the Worcester Corporation. Water power is derived from a fall on the Teme at Powick, and is developed by four inward flow turbines of the Victor pattern, two 54in., one 48in., and one 30in., the total turbine power being 500-horse power. There is also sufficient steam plant to generate the whole of the electricity, should the water supply fail. There are three vertical compound engines of the marine type, the cylinders being 15in. and 25in., and the stroke 16in., each of 290 indicated horse-power. The turbines and engines are connected by cotton driving ropes with the four Mordey Victoria alternators, each having a capacity of 125,000 watts, and absorbing about 200-horse power. The engine-room has a travelling crane, lifting 12 tons. In the boiler-house are four Babcock and Wilcox water-tube boilers, equal to about 900-horse power, fed with the river water by two duplex feed pumps. The current is taken to Worcester by two pairs of copper mains, at a pressure of 2000 volts. The Brush Electrical Engineering Company is the contractor for the machinery and electrical plant, and Messrs. Rowbottom for the building of the generating station; Mr. Leonard Wigan, A.M.I.C.E., being clerk of the works. Mr. Preece is the expert who has advised the Council. Worcester is the only municipal body supplying electricity by water power, and the new station is the largest water-generating station in the kingdom.

Railway engineering schemes continue to increase in number. The latest is a movement to induce the Midland Railway to extend its system in the immediate neighbourhood of Birmingham. The railway authorities at Derby have before them a proposal. It is suggested that, using the present rails to Water Orton, the Midland Company should from that place construct a line to skirt the town of Coleshill, and then proceed through Maystoke to Meriden and Allesley, and enter Coventry on its western side. From Water Orton to Coventry is 21 miles, as against 18½ from Coventry to New-street. It is proposed that the line should go thence to Rugby and on to Northampton, where there are Midland branches, and that to Bedford could be used as the line to London. The Midland journey from Birmingham to London would thus be shortened by 30 miles. The matter is, however, so far a suggestion only.

It is rumoured that a large consignment of guns and ammunition, all of the latest improved type, has been purchased and sent away from the Midlands by a roundabout route to Japan, being first consigned to another country in order to evade the Foreign Enlistments Act. The same firm is said to have been approached by emissaries of China for a similar purpose almost at the very time that Japan was negotiating.

Messrs. G. Kynoch and Co., Witton, Birmingham, are understood to have obtained a contract from the Government for the supply of 600 tons of cordite, the delivery to extend over three years. The firm have mills in Yorkshire, but will probably also erect new ones in another part of the kingdom. Hitherto cordite has been manufactured exclusively at the Government works at Waltham Abbey, and this obtaining of a portion of their supplies from the trade is a new departure.

Local engineers express satisfaction at the announcement that the Government has decided to spend 520 lakhs of rupees this year and 500 in each of the following two years on railway construction and irrigation works.

Birmingham manufacturers of copper wire have good reason for their complaints this week of the rapid development of French competition in this country. Several leading French companies, acting as a syndicate, recently effected extensive contracts with American firms for copper at £3 per ton below existing rates. Fortified by this advantage, the agents of the syndicate's firms are now offering copper wire for telegraph and other purposes wherever needed in England at less money than Birmingham manufacturers can produce it, and contracts are being accepted for the whole of 1895.

## NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

*Manchester.*—A continued absence of any improvement in the position throughout the engineering and iron trades of this district is again the general report, and any hopeful prospect would seem now to have disappeared altogether, so far as the present year is concerned. For the immediate future a slow dragging trade is all that is looked forward to; but, there are apparently some sanguine expectations that the spring of next year may bring forward a revival of activity. In the meantime, makers and manufacturers of iron are finding it difficult to secure business to keep them even partially going at anything like remunerative rates, and the present position is about as unsatisfactory as it could well be. The coal trade also continues in a depressed condition, so far as all descriptions of fuel for general manufacturing purposes are concerned, and the tendency as regards these would seem to be rather in the direction of even still lower prices, owing, not only to the excessive local supplies, but to the keen competition from other districts.

Only a very slow business continues to be reported on the Manchester Iron Exchange, and although there was a full average attendance at the market on Tuesday, a dull, depressed tone prevailed generally. For pig iron business continues to be restricted to the smallest possible quantities, consumers and merchants being in most cases more than sufficiently bought for present requirements, and the tendency of prices—where there is business offered to really test them—is in a downward direction. Lancashire makers still quote nominally on the basis of about 39s. 6d. and 40s. for forge to 42s. for foundry, less 2½ at the works; but the business they are doing at these figures is restricted to only occasional small parcels, sold to regular customers. District makers are generally in the position that their books are practically full for the next month or two; but in some instances iron is being thrown upon their hands, owing to customers not taking their full deliveries, and consequently they have to seek for orders in the market. Makers who prefer to go on simply with contracts are, of course, holding firmly to full recent quotations, but where they do come upon the market they have to give way to secure orders, and 39s. now represents the full average selling figure for forge Lincolnshire, with foundry quoted about 40s. 6d. to 41s., and Derbyshire foundry about 45s. up to 46s. net cash delivered Manchester. Outside brands offering here are decidedly easier; good foundry Middlesbrough can now be bought readily at 44s. 4d., with good-named brands quoted at 44s. 10d. net cash delivered Manchester, whilst as regards Scotch iron, it is difficult to get more than 48s. net prompt cash for Eglinton, delivered at the Lancashire ports.

The position in the finished iron trade still shows no improvement, very few forges having work sufficient to keep them running more than about four days per week, and although makers still quote late rates, these are difficult to maintain where new business is concerned. The very small orders just now coming upon the market offer, however, no inducement to give way, but if anything like good specifications were put forward there is little doubt some concessions would be forthcoming to secure them. Delivered in the Manchester or Liverpool district, quotations for Lancashire and North Staffordshire bars remain at £5 7s. 6d. to £5 10s.; Lancashire and Staffordshire sheets, £7 to £7 5s.; and for Lancashire hoops, £5 17s. 6d. for random, and £6 2s. 6d. for special cut lengths. With regard to hoops, I may mention that a fairly large South American order, which it was generally anticipated would be placed in this district, has been secured by German manufacturers, and this has given rise to the question whether the Association list rates should be made binding only as regards home trade, leaving makers free to compete for foreign business. Nut and bolt makers report only very few orders giving out, and these are competed for at very low figures, the effect of foreign competition being also complained of in this branch of industry.

In the steel trade only a very quiet business continues to be reported with low prices ruling. Ordinary foundry hematites do not now average more than 52s. 6d. to 53s., less 2½; ordinary basic billets, £4 net cash; steel bars, £6 to £6 2s. 6d.; and boiler plates, about £6 5s. per ton, delivered in the Manchester district.

In the metal market list rates for manufactured goods remain unchanged, but buyers continue to purchase only in the smallest possible hand-to-mouth quantities.

The position as regards the engineering industries still shows no indication of improvement; in the locomotive building trade especially the outlook is most discouraging, and I hear that one of the largest firms in Lancashire may possibly have to close altogether before very long, owing to the entire absence of new orders coming forward.

The reports of the engineering trades union organisations show no appreciable change in the position, except that the returns of unemployed members are rather more favourable than they were last month. The returns issued by the Amalgamated Society of Engineers show a slight decrease in the number of members in receipt of donation benefit, but there are still very nearly 9 per cent. of the total membership in receipt of out-of-work support. In the Manchester district there has been a steady but small decrease in the number of unemployed members during the past fortnight; the position is, however, still anything but satisfactory, as very nearly 10 per cent. of the local membership continue in receipt of out-of-work support.

The Steam Engine Makers' Society also reports a slight decrease in the number of unemployed members, although not sufficient to have any appreciable effect, as there are still over 5½ per cent. of the total membership in receipt of donation benefit. With regard to the general condition of trade, the reports from the various districts continue very unsatisfactory so far as any immediate prospects of improvement are concerned; in some important districts the tendency is even towards a further decline, and it is only here and there that any increasing activity is reported. The general conviction amongst the leading officials of the trades union organisations is that no improvement in the engineering industries can be looked forward to, at any rate during the present year, but the executive of the Amalgamated Society of Engineers are, I understand, in possession of information which is regarded as of a very trustworthy character, that with the ensuing spring there is every probability of decidedly improved conditions.

The winter discussion session of the Manchester Association of Engineers should prove an attractive one for the members, as the syllabus contains a number of specially interesting papers. Mr. J. Holliday, of Dublin, is to contribute a paper on "The Cost of Steam Raising," and this will be followed by a contribution by Mr. James Atkinson, M.I. Mech. E., on the "Modern Development of the Gas Engine." Mr. Joseph Nasmith will deal with the recent considerable developments of "Prepayment Meters," which are now so largely adopted by gas-users in small dwellings. A specially interesting paper will be one by Messrs. D. Selby-Bigge and G. H. Firth on "Electricity as the Future Motive Power in the Textile Industries." Mr. J. West, M.I.C.E., of Manchester, who is an authority on all questions connected with the application of gas, is to read a paper on "Gas-lighting for Workshops," and Mr. R. H. Tweddell, M.I.C.E., will contribute a paper on "Hydraulic Machine Tools," with regard to which he is also a well-known authority, whilst one evening is set apart for an open discussion, to be opened by a communication from Mr. A. Saxon, on "Steel Castings."

The coal trade still shows no appreciable improvement, except so far as the season of the year brings forward the usual increased demand for housefire consumption. This is enabling many of the collieries to get into more regular work, and tending to stiffen up prices for the better qualities of round coal, but there is no really upward move, except that list rates are being more firmly adhered to, best Wigan Arley now fetching 11s. up to 11s. 6d., with Pemberton four-foot and seconds Arley quoted at 10s. to 10s. 6d., and common house-fire coals about 8s. to 8s. 6d. at the pit mouth. Other descriptions of fuel for iron-making, steam, and general manufacturing purposes still meet with only a very slow sale, with supplies plentiful, engine fuel being if anything even more of a drug upon the market, owing to the increased production of slack, resulting from the larger inquiry for house-fire coals. Steam and forge coals at the pit mouth do not average more than 7s. to 7s. 6d. per ton, and the outlook with regard to this class of fuel is anything but encouraging, as there would seem to be a probability when the shipping season to the Baltic ports is closed that a considerable quantity of common round coal from the Yorkshire district may be forced upon this market, and already there are indications that some of the Yorkshire coalowners are seeking for inland business at prices under their current quoted rates. There are also large supplies of engine fuel coming in from other districts at extremely low figures, Derbyshire slack being offered at as low as 1s. 6d. to 1s. 9d. at the pit mouth, and prices generally show a weakening tendency. At the pit mouth, Lancashire slack averages 3s. 6d. to 4s. for common sorts, 4s. 6d. to 5s. for medium, up to 5s. 6d. for the best qualities, and to effect clearance sales specially low rates are frequently quoted.

In the shipping trade a moderate business is still reported, with ordinary Lancashire steam coal ranging from about 8s. 6d. to 9s. per ton, delivered at the Garston Docks or the High Level, Liverpool.

*Barrow.*—During the past week smelters of iron in North Lancashire have not done a very big business; in fact, rather the reverse is the case. Although there has been a certain amount of firmness in the market towards the end of the week, there has been no appreciable difference in the demand. Consumers on every hand have few requirements, and are only placing small orders. Steel makers are using fair supplies, and are likely to want more; in the meantime, however, the trade doing is small, and the same inertness that has been so noticeable for so long is very prominent. Prices are much about the same, being easy. Makers are asking 44s. 6d. to 45s. 6d. per ton for parcels of mixed numbers of Bessemer iron, and in the warrant market holders are asking 43s. 4d., with buyers offering 43s. 3d. per ton, net cash. Thirty-three furnaces are blowing, and their output is quite sufficient to cover the wants of consumers, for the stores of iron had been added to during the week to the extent of 20 tons, making the total held 158,510 tons.

The steel trade is still quiet. The demand for steel shipbuilding material continues to be small. Some fair orders are held for Barrow and Belfast builders, and the mills at Barrow are likely to be fairly employed for a while yet. In the meantime there are some orders in the market. Ship-plates are at £5 7s. 6d., angles at £5 10s., and boiler-plates at £6 per ton. The inquiry for rails is without change, and little is doing. Heavy sections are at £3 15s., light rails at £5 5s., and colliery sections at £5 10s. per ton. There is a fair demand for tin-plate bars, and it is expected that this inquiry will be considerably strengthened in the immediate future. The current quotation is £3 17s. Other sections are very poorly inquired after, and next to nothing is doing.

There is a fair amount of activity noticeable in the shipbuilding and engineering trades. Shipowners are, however, not very much disposed to place orders just at present.

The demand for iron ore is quiet, especially on general account. Average sorts are at 8s. 6d. to 9s. per ton net at mines.

East-Coast coke is in fair demand at 17s. per ton delivered.

The shipments of iron and steel from West-Coast ports for the past week reprecent 9100 tons, as compared with 13,325 tons in the same week of last year, a decrease of 4225 tons. The shipments to date stand at 591,086 tons, as compared with 596,167 tons last year, a decrease of 5080 tons.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE variable weather we have had during the last ten days has unfavourably affected the house coal trade, but there are now evidences of its becoming firmer. The advance of 6d. to 1s. per ton has been generally obtained, and at the date of writing the cold has set in, accompanied with damp, which is certain to cause householders to complete stocking for the winter. Although the demand in the Barnsley district has fluctuated considerably, business has now become somewhat steadier, and a considerable number of collieries are working the full time. New sinkings are being proceeded with at Hickleton Colliery, which, with the commencement of the work at Grimethorpe, will materially increase the output of the district. The Mitchell Main Colliery Company, to which the new workings at Grimethorpe belong, has taken over the Darfield Main pits, and when the new collieries at Grimethorpe are completed, the company's operations will extend to an area of underground work of three miles. With a yearly output of marketable coal increased to one million tons, the Mitchell Main Company will take its place in the front rank of English collieries. Other owners are at present employing colliery engineers to test the coal boundary of their land with a view to extension. These investigations are mainly confined to the Silkstone bed. The metropolitan demand is reported to have been merely moderate. Silkstones fetch from 8s. 6d. to 11s.; Barnsley House from 8s. 9d. to 9s. 6d. per ton; second qualities, from 7s. per ton upward—all prices at the pit. In steam coal values continue steady, Barnsley hards making 7s. 9d. to 8s. 9d. per ton; inferior slacks from 7s. 6d. per ton. Heavy deliveries are being made to railway companies on account of contracts. Gas coal is quoted at from 7s. to 8s. 6d. Manufacturing fuel is somewhat depressed, owing to the small demand in the textile districts. Good slacks are from 4s. 6d. to 5s. 6d. per ton; pit slack, from 3s. 6d. per ton.

The position taken up by the colliery enginemen, boilermen, and firemen is not quite so acute as it was last week. Although their Union, which is not associated with the Miners' Union, had decided to adhere firmly to their demands, and to stand by the notices they sent out a fortnight ago, a more conciliatory attitude prevailed at the last conference with the coalowners held at Sheffield on Monday. It was then arranged that the notices which would have expired this week should be withdrawn and work continue, pending another meeting of the coalowners to be held a fortnight hence at Sheffield. Had this arrangement not been made, and the men still adhered to the position taken up at Barnsley, a serious rupture was inevitable at the Yorkshire coalfield, for the pits could not possibly go on working without the colliery enginemen and their colleagues. It is not expected that the difficulty will lead to any stoppage in the coalfield.

A better demand for crucible steel is reported from the Continent, but the fresh business is not evenly distributed, several firms being well employed, while others complain of want of work. Taken all round, however, the crucible steel trade is reported to be more active than in the corresponding period of 1892. Last year, of course, very little was doing owing to the stoppage of the collieries.

Bessemer billets are quoted at £5 10s.; bar iron, £5 10s. to £5 15s.; wire rods, £5 5s.; and rope rods and high carbon rods, £8 8s. per ton. The iron market is very much as last reported, hematites being at 50s. to 52s. 6d. per ton, according to brand; while common forge iron is quoted at 38s. 6d. per ton in Sheffield, with supplies considerably in excess of the demand.

An important order for armour-plates was received in Sheffield this week from the British Admiralty. If these orders for armour-plates were followed by a revival in the shipbuilding yards and some signs of activity in the construction of foreign railways, Sheffield would soon be extremely busy. As it is, the war material branches are about the only departments in which full employment is given. No doubt the low freights for cargoes militate against shipowners adding to their fleets, and the unsatisfactory traffic returns are responsible for the holding back of orders for railway material. A good deal of wagon work has been locally placed, but the facilities for production are so great that even large orders are soon completed. Engineering firms report that business is not as good as it ought to be. Boilermakers, on the other hand, are well off for work, and there is, perhaps, no branch of our heavy trades in which more progress has been made of late years.

In the lighter industries both the silver and cutlery trades are feeling the season demand for goods adapted for Christmas and New Year. With the setting-in of the winter demand many novelties in electro-plate, silver and Britannia metal have been placed upon the market. Some of the leading firms are working extra time, and will continue to do so up to the end of the season. A distinct feature of the silver trade is the demand for sterling silver goods. The low price of silver narrows the difference between these goods and the best quality of electro-plated nickel. Customers therefore prefer to pay the extra cost to have their table appointments of silver. There is more doing in cutlery, and the next returns of the United States Consulate will maintain, if not exceed, the satisfactory increase reported on the 30th of September last. It is said that the American market is taking an unusual quantity of second-rate cutlery from Sheffield. This is rather against the usual way of the Americans, and may probably be but a temporary feature of the trade. Orders are undoubtedly coming in very freely, and prospects are decidedly more encouraging. The Tariff favours the commoner grades of cutlery more than the expensive brands, and this probably accounts for purchases running so much in the cheaper qualities. There is more doing in our own home markets, season orders having come to hand earlier than in previous years.

In addition to the Antwerp awards already announced, Messrs. William Lockwood and Co., Ocean Works, St. Mary's-road, Sheffield, have been awarded two silver medals for their patent flangeless piston rings. This is the highest and only award for piston rings.

The Liverpool ivory sales have been held this week. There were only about seventeen tons on offer. The American buyers were present in force, and purchased freely. Prices went up from £10 to £12 per cwt.

Mr. Emerson Bainbridge, J.P., of the Nunnery, Blackwell, and other collieries, and who is also chairman of the East to West Coast Railway, has contributed a thoughtful and effective article to the *Contemporary Review* this month, bearing on the eight hours question. Mr. Bainbridge, since its publication, has received a number of letters on the subject. One is from Mr. Henry Simon, of Mount-street, Manchester, who informs Mr. Bainbridge that amongst the instances which he gives of foreign, especially Belgian work, introduced into this country, there is omitted what he—Mr. Simon—considers to be the most glaring instance of this foreign competition, viz., the fact that the comparatively new railway station at Middlesbrough is, as a local ironmaster told him some time ago when there, "every pound of it Belgian iron." "What are we to say," asks Mr. Simon, "if the capital of that iron district which produces the cheapest gets its station ironwork from Belgium?" Mr. Simon adds that while his personal inclinations, wishes, and moral feeling are distinctively in favour of allowing the labouring classes, and everybody else, the largest possible share of the comforts of this life, he cannot but entirely admit, with Mr. Bainbridge, that the way in which this eight hours movement is now progressing is simply hastening the inevitable moment at which England's pre-eminence in trade will begin to rapidly decrease. "All large strikes," he holds, "are so many invaluable helps to foreign industries. Considered from a continental and humanitarian standpoint, the advantage may probably be seen in this policy; but do the working classes really intend thus unselfishly to help their foreign competitors?" Most people will think with him that they do not; the explanation being their utter incapacity to see the folly which they are perpetrating. They have some capable, intelligent men amongst their leaders, and surely the time cannot be far distant when the more thoughtful of these people will declare the doctrine of sound business plainly to their constituents, whether it offend them or whether it please them.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

MORE cheerful reports are this week given by iron and steel manufacturers relative to the state of trade, and certainly there is not that amount of pressure to sell that has been shown hitherto this month and for a part of September. The speculative fraternity, who have been operating in iron, appears to have recovered confidence, and are not disposed to further depress prices by putting so much iron upon the market. It is pretty well recognised that there has been no change in the condition of trade to justify the relapse in prices that has recently taken place, and that if speculators had not rushed their iron upon the market, prices might have been kept up. Trade is undoubtedly better than it was last year, as may be seen from the railway traffic returns, and the production and shipments of pig iron; indeed, it may be said that this year's production and exports of pig iron exceed those of any previous year, while the increase of stock has been only small, and is very much less than it was in almost every year of the past ten; in fact, in one year at the end of September North of England pig iron makers and the warrant stores held four times as much iron as they do at present—nearly 730,000 tons. The average quoted price of No. 3 Cleveland pig has also this year exceeded that of last year by fully 1s. per ton, being this year no less than 35s. 10d., which is considerably above the figure that has ruled in at least half of the last ten years. The finished iron and steel trades have not been anything like so good this year as they might have been if business had not been hampered by the strikes of the engineers, moulders, and patternmakers, which has seriously affected the output of the shipyards, and consequently of the plate and angle mills, which in this district depend upon them for the bulk of their work. Work has been thrown back so much that there are now vessels that have been waiting for their engines four months or more.

Sales of Cleveland pig iron have been more numerous this week than they have been for some time past, the chief demand being for No. 3, which is scarce, and which is needed for export. In this month the shipping demand is always extra brisk, as it is the last of the northern navigation season, and consumers abroad who get their supplies through Baltic ports have to get in what they will need in the winter. But the exports are not nearly so good as they were last year; thus this month to Wednesday night the pig iron exports from the Tees reached 46,310 tons, as compared with 37,915 tons last month, and 58,142 tons in the corresponding month last year to 17th. Makers have generally this week been quoting 36s. per ton for prompt f.o.b. deliveries of No. 3 Cleveland pig, and some of the leading firms whose stock is almost *nil* have asked and secured even 3d. more. But merchants and some producers have been selling at 35s. 9d., and they were ready to accept 36s. for forward delivery. Cleveland warrants have not been largely offered, and the extent of the fluctuations in price this week has only been 1½d. per ton.

The stock of Cleveland pig iron held by Messrs. Connal and Co. on Wednesday night was 89,067 tons, or 678 tons decrease this month.

No. 4 Cleveland foundry pig has shown considerable improvement in demand, and as the supply is hardly equal to the requirements the price has advanced 3d. per ton, thus restoring the ordinary difference between the prices of No. 3 and No. 4 foundry, which is 6d. per ton, but which difference has not existed for a very considerable period, the commoner quality being relatively cheaper than No. 3, as it has been more plentiful. Forge qualities have not advanced because the supply is in excess of the requirements, and these qualities have again become "a drug upon the market." Grey forge can be bought at 34s., and is thus 1s. 3d. cheaper than No. 4 foundry pig, though the usual difference is no more than 6d. The supply of East Coast hematite pig iron is greater than the consumption, and the price of mixed numbers has dropped to 42s. 9d. per ton, though ore prices are tending upwards, and it does not appear likely that any reduction in the cost of production will be effected.

At the quarterly meeting of the Middlesbrough Chamber of Commerce a communication was read from Mr. Jeremiah Head, of Middlesbrough, which showed that in a certain district in the United States pig iron was being produced at less cost than in Cleveland, and was sold at a lower price than has ever been touched for Cleveland iron, 29s. being the lowest ever reported for No. 3. Mr. Head has been in the United States for some time on professional business, and has visited the region in question. It is in Alabama, and Mr. Head says of it that it is the "Cleveland" or cheap common iron centre of America. Pig iron containing half the phosphorus that there is in Cleveland pig iron is being made there at a cost price at works, including all except debenture interest, of 24s. 2d. per ton, and is being sold at from 26s. to 29s. per ton on trucks at works; 28 lb. per ton extra over 2240 lb. is allowed for sand. This pig iron is finding its way into every part of the United States, even into Pittsburg. As yet it has not been used for steel. Large cast iron pipes up to 60in. diameter are being made and sold at £3 15s. 6d. per ton at works, and are forwarded to all parts of America. They are not quite so well finished as Ormesby pipes, but are good enough. Under circumstances like these there does not appear much chance for England exporting pig iron or pipes to the United States, notwithstanding the more favourable Tariff Act that has been passed.

A rather better demand is reported by some of the finished iron and steel manufacturers. It is satisfactory that Messrs. Dorman, Long, and Co. have this week recommenced operations at their West Marsh and Britannia Iron and Steel Works, Middlesbrough, after a stoppage of about two months, during which they have added considerably to their plant. On the other hand, the Dar lington Steel and Ironworks have been entirely closed, and the directors, at their meeting on Monday, stated that the condition of trade did not encourage them to look forward to an early resumption of operations. It is, therefore, thought advisable to realise the floating assets of the company, without, however, disposing of any of the loose plant or tools, which would be needed to re-start the works. Out of the money thus obtained the liabilities will be met, and the meeting was adjourned for a month to permit this to be completed. Ship-plate makers are fairly well employed, notwithstanding the dulness in the shipbuilding industries. At the shipyards on the Tees and at Hartlepool at least 40 per cent. of the men usually employed at the shipyards are idle, and a hard winter is looked for; as Lloyd's returns show there is much less work booked now than there was in the early part of the year. Thus on the Wear there are only 32 vessels of 85,653 tons, against 43 vessels of 112,025 tons a year ago; on the Tyne 53 vessels of 131,773 tons, against 51 of 121,956 tons; on the Tees, 21 vessels of 45,252 tons, against 25 of 65,170 tons; and at Hartlepool and Whitby, 13 vessels of 37,259 tons, against 18 vessels of 47,630 tons. Still at present the steel-plate and angle makers are fairly well employed, and maintain their prices. The same figure is quoted for iron as for steel plates —£4 17s. 6d., less 2½ per cent. f.o.t.—as it costs more now to produce iron plates than to roll steel plates. Iron ship angles are £4 12s. 6d., and steel ship angles £4 15s., both less 2½ per cent. and f.o.t. Heavy steel rails are at £3 12s. 6d. net at works, and a rather better inquiry is reported. Many of the moulders who have been on strike are still unemployed, the masters being unable to find work for them, as orders have been driven to other districts. A considerable proportion of the engineers are likewise unable to work.

Some of the ironmasters are again, as is usual in the autumn season, being put to inconvenience owing to lack of trucks, and the question has been under the consideration of the Middlesbrough Chamber of Commerce, who have asked the firms to keep a record of the short supplies, together with details of delay, loss, and expense incurred, so that definite evidence may be forthcoming in case an appeal has to be made to the Railway Commissioners. The North-Eastern Railway managers have asked some of the firms to give them an idea as to what they will require in the way of goods wagons over the next five years, and other questions as to the probable lives of their collieries, &c.

At the meeting of the North-East Coast Institution of Engineers and Shipbuilders, held at Newcastle on Tuesday, the Council reported that the number of members was 954. The President—Mr. Thomas Richardson—delivered his inaugural address, in which he dealt with the question of economical production and the competition of foreign countries. He deprecated the doctrine which is so often made use of, as to our superior capacity as handicraftsmen, and stated that the extended and universal adoption of machinery had enabled the foreigner to compete with us—and especially was this so in the engineering industry. The President also touched upon the application of electric driving of machinery at home and abroad, and showed that there was a large saving in steam power by the use of the electric system of working, as well as a considerable reduction of labour.

The coal trade continues active, notwithstanding that there is less required for Scotland, but the export demand is strong, and merchants are anxious to get as much coal away as possible this month. Wages in the Northumberland coal trade are not to be changed this quarter, as the Conciliation Board has found that though trade was so brisk last quarter, prices were not materially raised. The Northumberland collieries generally are working eleven days per fortnight, which is full time, and in Durham there are very few pits which are not in full operation.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE is a rather better feeling in the iron market, with still much room for improvement. Scotch warrants have been fairly steady, with only a moderate business. Buyers are acting with caution, for although the miners' strike is now practically over in the West of Scotland, it is not yet quite clear whether business is likely to come away with anything like activity. Transactions have taken place at 42s. 6½d. and 42s. 6d. cash. There is very little inquiry for Cleveland warrants, which are worth nominally 35s. 5½d. cash. Cumberland hematite has been weaker, declining from 43s. 5½d. to 43s. 3½d. cash.

The blast furnaces are now being steadily relighted, about twenty having been added to the active list within the last ten days; the number blowing is, however, still much smaller than at this time last year. Several weeks must elapse before the furnaces now going in will be in a position to make their full complement of pig iron. Several brands continue very scarce, and the prices of these are fairly steady, but the general tendency of values is downwards, some brands having fallen from 6d. to 2s. 6d. per ton in the course of a week.

The following are the current prices of makers' pig iron:—G.M.B. f.o.b. at Glasgow, No. 1, 44s. per ton; No. 3, 42s. 6d.; Monkland, No. 1, 47s. 6d.; No. 3, 42s. 6d.; Carnbroe, No. 1, 47s. 6d.; No. 3, 46s.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, No. 1, 52s. 6d.; No. 3, 48s. 6d.; Calder, No. 1, 53s. 6d.; No. 3, 49s. 6d.; Summerlee, No. 1, 55s.; No. 3, 50s.; Coltness, No. 1, 56s.; No. 3, 51s.; Glengarnock at Ardrossan, No. 1, 54s. 6d.; No. 3, 49s. 6d.; Eglinton, No. 1, 48s.; No. 3, 46s.; Shotts at Leith, No. 1, 57s. 6d.; No. 3, 51s. 6d.

The market for hematite pig iron is a little more active as far as regards business done direct with the producers; while there seems no inducement to speculation, it is evident that the requirements of consumers are bound steadily to increase. The import trade in Spanish ore has been resumed, and freights are very moderate, enabling smelters to obtain supplies at comparatively easy rates.

The pig iron shipments are extremely small, amounting in the past week to only 1859 tons, compared with 3455 in the corresponding week. Of the total there was sent to Australia 155 tons, Germany 128, United States 100, Canada 80, Italy 100, Holland 50, Belgium 10, Spain 20, other countries 30, and coastwise 1186, against 1022 same week of 1893.

The finished iron and steel branches are getting into a rather more encouraging attitude, the works are being put in operation more fully, and makers are preparing for any demand that may arise; meantime business is on a restricted scale, and prices are nominal.

The export trade in manufactured goods is quiet. The past week's shipments from Glasgow embraced sewing machines worth £256; other machinery, £5321; steel goods, £3943; and miscellaneous iron goods, £13,952.

Reports with reference to the locomotive engineering branch are favourable, the principal firms have good orders in hand both for home and foreign railways. General engineers are but moderately employed. In the tool making branches business is irregular, some houses doing next to nothing, while others are fairly busy.

The strike of miners in the West of Scotland may now be said to be over, for although companies of men here and there still hold out in expectation of obtaining support from the English Federation, the great majority of the men have given up the struggle as hopeless, and made a rush for employment. This many of them are unable to find, owing to the roads and workings of the collieries being out of repair. While the quantity of coals raised is still limited, it proves more than equal to the demand, so that a further reduction has taken place in prices. The fall in the retail price of household coals in Glasgow in the course of the last three weeks has been about 40 per cent. Of course, by-and-bye, the public works will absorb much larger quantities, and the shipping trade is likewise expanding gradually. A fair demand is springing up for the Mediterranean from Glasgow, the clearances there in the past week amounted to about 22,000 tons. The loss in exports, owing to the strike, amounts to upwards of 2,000,000 tons, and this, it need hardly be said, will never be made up.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

A SIGNIFICANT fact of the week is that steamers in the course of a day or two will be loading no less than 5000 tons of tin-plates at Swansea, principally for the United States. This is not only encouraging for the great tin-plate centres, notably, Swansea, Llanelly, Briton Ferry, and the Newport district, but also for the iron and steel works. Ironmasters are quite satisfied that until new countries are opened out rails must play a very secondary part; and it is to tin-plates and to the increasing uses of steel in the country that they look for business. I lately saw in Radnorshire terne plates adroitly used as garden fences, and reported to be cheaper than brick or stone masonry. The artisan placed them himself, and saved the labour of mason.

Last week the Swansea shipment of tin-plates was 60,469 boxes, make received from works 69,201 boxes, showing a good deal of activity, and proving that a more settled condition of things exists amongst the workmen. So far prices have not moved, but a few consignments such as will be recorded next week will leave stocks much below an ordinary level, and lead to improved quotations.

In the Newport district a better tone prevails amongst tin-platers, and I note that in the Briton Ferry district a good average make is recorded. This week the Earlswood Tin-plate Works, Briton Ferry, which have been idle for a year or so, were re-started. These give employment to 140 hands.

Dowlais steel works this week were as busy as I have seen them for some time, both the upper and lower works, and at Cardiff not only is a good make of pig maintained, but steady progress made in completing the works. Probably in two or three months this will have been accomplished.

There has not been much doing in rails, with the exception of some despatches to Highbridge. The make of steel bar has been moderately good. Blaenavon, Cyfarthfa, and Ebbw Vale maintain fair activity in mills and furnaces. Tredegar and Rhymney are putting forth their best efforts in coal development, and in the manufacture of coke; and as I note this week but few arrivals of pig iron—only one small one coming in from Ardrossan—there is a prospect that the heavy stocks I saw lately at various works will have a chance of being lessened. Swansea imported this week 200 tons steel scrap, and 2600 tons of iron ore. Of the latter Ebbw Vale and Dowlais also received large cargoes.

Swansea quotations this week are only slightly altered from those of last week. Glasgow pig is a little improved, 42s. 5½d. to 42s. 6½d.; Middlesbrough, 35s. 5½d.; Middlesbrough hematite, 42s. 4½d. Welsh bars remain at £5 2s. 6d.; steel rails, heavy, £3 15s. to £3 17s. 6d.; light, £4 10s. to £4 15s. Cardiff quotation for rails, heavy, is £3 12s. 6d.

Other Swansea quotations are:—Sheet iron, £6 to £6 10s.; steel sheets, £6 5s. to £6 7s. 6d., with usual extras for higher gauges; Bessemer steel bars, £4 to £4 2s. 6d.; Siemens tin-plate bars, £4 to £4 2s. 6d.; tin-plates, makers' quotations, Bessemer, 10s. 3d. to 10s. 6d.; Siemens, 10s. 6d. to 10s. 9d.; ternes, per double box, 28in. by 20in., 20s. to 24s.; best charcoal, 12s. to 12s. 6d.; wasters, 6d. to 1s. less in each class. Block tin £69 7s. 6d. to £69 10s. Anthracite coal, 8s. 9d. to 12s. 6d., according to quality.

The coal trade continues vigorous, and shipments have been considerable at all ports. Good healthy vitality is very noticeable in the Newport district. Some labour troubles have affected the output of certain collieries, and perhaps kept prices up more firmly. On Saturday best steam was quoted at 12s.; the latest quotation now is 11s. 6d. to 11s. 9d., Cardiff. Other prices are:—Seconds, 11s. to 11s. 3d.; best Monmouthshire, 10s. 3d. to 10s. 9d.; dry sorts, 10s. to 10. 3d.; small, 4s. 9d. to 5s. 3d. House coal has kept up remarkably well, and now a good season is evidently before this class of coal. Even now, before the autumn has disappeared, there is a pressure of business, and prices may be expected to advance. Best household commands 11s. to 11s. 3d.; No. 3, Rhondda, 10s. 3d. to 10s. 6d.; brush, 8s. 6d.; small, 6s. 6d. No. 2 Rhondda, 8s. 6d. to 8s. 9d.; through, 6s. 9d. to 7s.; small, 4s. 6d. to 4s. 9d.

Cardiff quotations for pitwood are 15s. to 15s. 3d., demand good, but market glutted. Patent fuel active, 11s. to 11s. 6d. Coke tolerably brisk; furnace, 15s. to 16s.; foundry, 17s. to 17s. 6d.; special, 21s. Swansea exports of patent fuel only moderate; principal cargoes last week were, 2470 tons to France, 1300 to Italy, 1290 to Algiers. Iron ores quieter, prices remain—Cardiff, 10s. to 11s. 3d., according to quality. Swansea to 12s.

A new labour difficulty has cropped up amongst the tin-plate men, not this time against employers, but against their doctors, who are agitating for increased fees. Present rates are, men, 8d. per month; boys, 4d. The doctors now demand 1s. adults, and 6d. boys, and the ballot box is to be brought into requisition to settle the dispute.

The prominent subject at Cardiff of late has been the probability of the Bute Docks being acquired by the Corporation and then of the formation of a Harbour Trust. A leading official of the Docks is reported to have said that the "one man rule" is coming to an end. With all respect for the official I do not believe it. The Taff Vale Railway objection to join has to be considered, and leading authorities at Cardiff urge that the amount required by the Bute Docks Company is such that in borrowing money to meet it no limited liability company could float. A few weeks will see whether anything will come of it. The Barry Docks' directorate have written to inquire the particulars of the Harbour Trust, as suggested by the Corporation.

The Birmingham water scheme continues to make good progress amongst the Radnorshire hills. Over 600 men are now comfortably hutted for the winter, and in the spring this number is to be increased considerably. The district is well wooded, and one of the initiatory steps is being taken in levelling the trees, many of which are very fine. Nantgwilt, where the principal engineer resides, was surrounded with a belt of wood, which is nearly cleared. Shelley the poet made this a place of exile, and we see that a local contemporary has suggested that Birmingham—in keeping with her traditions—should utilise some of the timber in making mementoes of the poet.

The dispute of the National Colliery Company, Wattstown, has been brought to trial. A fortnight ago the company summoned twelve of its men for absenting themselves without notice. The men's contention was, that the company had introduced new method of screening, and the result was one thousand men left work. The summons of twelve of these was an initiatory step. On Monday the trial took place before the stipendiary magistrate, Mr. Ignatius Williams, at the Tonypandy Police Court. Employers and men were ably represented, and at the close the magistrate ruled that the employers had violated a clause of the sliding scale agreement —No. 20 A—and that the men were entitled to refuse to work under the new system. Verdict for men, with solicitors' fees and costs.

Four hundred men at Rudry are at stop, but it is hoped that the slight difficulty will soon be removed. The Llanbradach men, No. 2 seam, continue to refuse filling trams until there is a revised price list.

The Llancriach Collieries Company has been registered with a capital of £15,000 in £10 shares.

The Institute of Marine Engineers, Bristol Channel Centre, had their annual gathering in Cardiff on Saturday. There was a large attendance, Professor A. C. Elliott in the chair. Capt. Pomeroy, responding to the toast of the port of Cardiff, said that imports and exports were advancing. The former now totalled two million tons per annum.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

A MODERATE business continues to be done on the continental iron market, and prices are fluctuating, with a downward inclination here and there. The position of the iron and steel trade in Silesia has not in any degree improved upon the week. Offers are being made at extremely low quotations, but still buyers show little inclination to come forward with their orders. The bar trade forms an exception to the rule, being in comparatively good activity, and there is also a tolerably fair business done in tubes.

Since previous letters very slight changes only can be noticed on the Austro-Hungarian iron market. In pig iron prices have stiffened a little, owing to the scarcity of that article. The rolling-mills are, as a rule, in fair employment, merchant bars meeting with a satisfactory demand. The girder trade is tolerably lively, while makers of steel plates and rails complain of a poor employment. Quotations for the different sorts of iron and steel are the same as last given.

The returns as to the condition of the French iron trade generally continue quite satisfactory. There is an undeniably increasing demand coming in for most sorts of iron, though several large contracts which had been counted upon as quite certain have not been given out at all; but there is, nevertheless, a sufficient amount of new work offering to keep the works in fairly regular activity. The tendency of prices is firm, but makers have, as yet, not ventured upon an advance, because they fear to be met with a strong resistance on the part of consumers. In the Department Nord the situation of the iron business is less hopeful, and some firms even fear that they will have to reduce quotations, at least for some articles. Hardware is generally neglected. In the Department Meurthe et Moselle pig iron is well maintained in spite of the exceedingly firm quotations for coke. Forge pig meets with a particularly good inquiry, while foundry pig is but weakly called for.

Business on the Belgian iron market has slightly increased in firmness, pig iron, as well as most sorts of malleable iron, meeting with a tolerably fair request. Prices of pig iron are rather easy on account of the large quantities of Luxemburg forge pig that is still thrown on the Belgian iron market, but for most sorts of finished iron quotations are well maintained, and a pretty confident tone generally prevails.

On the Belgian coal market prices have not altered for several weeks, only in the Liége district an upward inclination was to be perceived. With regard to the Belgian coal trade during the first eight months of last and of present year, import in coal is reported to have been 869,079 t. this year, against 865,810 t. for the same period the year before. Of these 397,082 t. were imported from Germany, against 366,462 t. in 1893. French and English import, on the other hand, has decreased. In coke, 214,862 t. were imported, against 162,959 t. for the same period the year before, which shows an increase of 52,000 t. This may chiefly be accounted for by the increasing import of coke from Germany, which was 158,460 t. in 1893, against 208,376 t. this year. Export in coal amounted to 2,748,820 t., against 2,735,237 t. in 1893, of which 141,187 t. were sent to Germany, against 149,877 t. in the year before; 2,166,830 t. were exported to France, against 2,161,075 t. for the same period in previous year. In coke, 577,161 t. were exported, which, compared to 605,062 t. in last year, shows a decrease of about 28,000 t.

There is no change, generally speaking, in the Rhenish-Westphalian iron business. The demand remains quiet, and quotations are still far from satisfactory, but makers show a fair confidence in the future, and are, for the present, content if they can secure sufficient work to keep their concerns going. The position of the iron ore trade is not favourable, most sorts being in very moderate request. Prices are the same as formerly quoted; for spathose ore M. 7·40 to 7·70 p.t. is given, while roasted ditto is paid with M. 10 to 11·20 p.t. at mines; inferior sorts cost M. 9·80 to 10 p.t. net at mines, and for Nassau red iron ore the old price of M. 9·20 p.t. is given. In Luxemburg and Lorraine, minette, 40 p.c. grade, is still to be had at M. 3·20 p.t., while for minor qualities M. 2·40 to 2·60 p.t. is quoted. On the pig iron market prices are, without exception, very firm. In the Siegerland the demand for present quarter is pretty regular; from abroad there has also been quite a fair inquiry experienced lately, and a large contract for forge pig has already been secured for the first two quarters of 1895. Spiegeleisen, 10 to 12 p.c. grade, still stands at M. 52 p.t., forge pig No. 1 is paid with M. 46 to 47 p.t., while for No. 3, M. 40 p.t. is given. Siegerland, good forge quality, quotes M. 44 p.t.; hematite, M. 63; foundry pig, No. 1, M. 63 p.t.; No. 3, M. 54 p.t. Basic is still paid with M. 45 p.t., while German Bessemer fetches M. 49 to 50 p.t. at works. Luxemburg forge pig costs M. 48 p.t. free Luxemburg. So far as prices are concerned, the situation of the malleable iron trade is less favourable than that of the pig iron business. Prices continue extremely depressed, and if an actual reduction does not take place, it is simply because prices have reached the very lowest point, covering not even the cost of production. Some works will have to suspend operations altogether unless an improvement in quotations sets in. The bar trade is in poor employment generally. If it was not for orders previously booked, the mills could hardly be kept going. Girders are in tolerably good demand, and so are hoops, for which a rising tendency in prices can be noted. Plates are still without improvement, and sheets have in some instances even decreased in demand. From abroad next to no orders are coming to hand. The state of the wire business continues extremely unfavourable. Only a small number of the iron foundries and machine factories are in good employment, the majority of the mills complaining of an almost total absence of fresh orders.

The following are the latest list prices per ton at works:—Good merchant bars, M. 105; rivet iron, M. 125; angles, M. 120; girders, M. 90 to 95; hoops, M. 108 to 115; billets in basic and Bessemer, M. 87; heavy plates for boilermaking purposes, M. 150; tank ditto, M. 130 to 135; steel plates, M. 125; tank ditto, M. 115 to 120; sheets, M. 140; Siegen thin sheets, M. 125 to 130; iron wire rods, common quality, M. 115 to 120; drawn wire in iron or steel, M. 103 to 120; wire nails, M. 125; rivets, M. 150; steel rails, M. 112 to 115; steel sleepers, M. 106; fish-plates, M. 115; complete sets of wheels and axles, M. 270 to 280; axles, M. 220; steel tires, M. 215 to 230; light section rails, M. 95.

NEW BRIDGE OVER THE WELLAND—AN ENGINEERING FEAT.—The new bridge which has been built for the Midland and Great Northern Railway Companies by Messrs. Handyside and Co., of the Britannia Ironworks, Derby, and London, was on Sunday, the 7th inst., placed in position over the river Welland at Spalding. The line being a single one, it was necessary to keep the old bridge in position for the working of the line up to the very last moment, and the new bridge had therefore been erected by the side of the old one. The last train passed over the old bridge at 9.30 a.m., and it was then lifted by hydraulic jacks and moved bodily away in seven minutes. It was shifted in the direction of Spalding Town by steam power, being run along a set of rails placed on either side of the river bank. The new structure, which is of three steel lattice bar girders, was then wheeled into its permanent position. The new bridge weighs over 200 tons, has a total span of about 111ft., is 34ft. wide, and was shifted into its present position in five minutes. The new bridge was tested by two fully loaded engines, each weighing about 80 tons, and about 4.30 a cattle train from Lynn passed over. The whole of the work was completed, and the roadway made good, within four hours. The bridge was designed by Mr. Richard Johnson, M.I.C.E., and its erection was carried out under the supervision of Mr. C. A. Kirby, M.I.C.E., of Boston.

## AMERICAN NOTES.

(*From our own Correspondent.*)

New York, October 11th.

The business situation is discouraging. Bank clearings are 22 per cent. below last year at this date, and 28 per cent below 1892 for same nine months. During the past three weeks there has been a fall in iron, steel, lumber, cotton, cloth, wool, coal, and coke. Numerous wages reductions have been made. The banks are overloaded with money, and speculation is at a standstill. Manufacturers are slow to contract for raw material. Consumers are covering present requirements. For iron there is increased activity at lower prices for girder rails, sheet and bar iron, but makers regard it only as a spurt. A steady improvement is not anticipated until after November 15th. New work of all kinds is freely projected for prosecution next year, and money is liberally subscribed under conditions. The improvement in trade and manufacturing will probably be slow during the winter, but an expansion of demand to unusual proportions is regarded as the inevitable result of prolonged restriction.

## LAUNCHES AND TRIAL TRIPS.

On Saturday Messrs. Caird and Co., of Greenock, launched a large new passenger steamer, built to the order of the Peninsular and Oriental Steam Navigation Company. The steamer, which is named the Simla, is intended for their India, China, and Australia mail services. She has a gross register tonnage of nearly 6000 tons, and, besides having accommodation for 145 saloon passengers, has a large cargo capacity.

On the 15th inst., Messrs. Ropner and Son launched a steel screw steamer of the following dimensions:—Length over all, 328ft.; breadth, 42ft. 10in.; depth moulded, 20ft. 11in. The vessel will be classed 100 A1 at Lloyd's, and carry over 4000 tons deadweight on Lloyd's freeboard. She has been built off the part awning-decked rule, with break poop and raised quarter-deck; cellular bottom for water ballast. Her triple-expansion engines are by Messrs. Thos. Richardson and Sons, Hartlepool, of 1100 indicated horse-power, with two large steel boilers working at 160 lb. She has been built for Bristol owners, and the name of Dovedale was given to her by Miss Ropner, of Preston Hall.

On Saturday last the steel screw steamer Kirkwall, recently launched by Messrs. the Blyth Shipbuilding Company, of Blyth, for the Kirkwall Steamship Company, of Cardiff, Messrs. Stephens, Mawson, and Goss being the managing owners, was taken to sea for her official trial trip. On the speed trials the machinery gave every satisfaction. The Kirkwall is designed to carry a large cargo on a light draught of water, and is fitted with the latest machinery for working both vessel and cargo. The Kirkwall will be commanded by Captain Hesketh, and has been under the supervision of Mr. Brewer, superintendent engineer to the company, during construction. The engines are of the triple-expansion type, and have been fitted by Messrs. the North-Eastern Marine Engineering Company, of Wallsend-on-Tyne. This is the fourth ship the Blyth Shipbuilding Company have built for Messrs. Stephens, Mawson, and Goss.

There was launched on Monday afternoon from the West Yard of Messrs. C. S. Swan and Hunter, of Wallsend-on-Tyne, a fine cargo steamer of special type and well-known design, being an improved description of partial awning deck steamer. The dimensions of the vessel are 324ft. by 41ft. by 23ft. 1½in. moulded, and she has been designed by builders to carry a deadweight cargo of 4350 tons on a moderate draught. She will also carry an exceptionally large measurement cargo, rendering the vessel very suitable for Indian trade. The steamer has been built to the order of Messrs. J. J. and C. M. Forster, of Newcastle-on-Tyne, and is the fourth vessel which has been built by Messrs. C. S. Swan and Hunter for the same owners. On leaving the ways the steamer was named the Newlyn by Miss Dorothy Forster, of Newcastle, and was then taken down to the works of the Wallsend Slipway and Engineering Company to receive her propelling machinery, which will be of the latest type, cylinders 23in., 38in., 51in., by 39in. stroke. During the construction the vessel has been surveyed by Captain Sarah on behalf of the owners, who, together with a large party, witnessed the launch.

On the 15th inst. Messrs. Irvine and Co., West Hartlepool, launched a steel screw steamer of about 4000 tons deadweight carrying capacity, built to the order of Messrs. Evan Thomas, Radcliffe, and Co., Cardiff. The vessel will take Lloyd's highest class, and has been built under special survey. Her dimensions are 315ft. by 42ft. 6in. by 20ft. 9in. The deck erections consist of poop, quarter-deck, and partial awning deck. The saloon and cabins for captain and officers are fitted up in the poop. The engineers are berthed in house at after end of bridge, and the crew at fore end. The hull is built on the web frame principle, and besides being fitted with ordinary water ballast tanks in cellular double bottom, she is fitted with a new arrangement of deck water-ballast tanks, which is a patent of Mr. M. Hill's, of Newcastle-on-Tyne. With this arrangement the difficulty of getting sufficient ballast into vessels of this class, without displacing cargo space, is got over. The construction of these deck tanks also forms an effective means of strengthening such vessels having a break in their decks, and the top of the tank forms a means of communication between the bridge and poop, thereby obviating the necessity of going into the well. Large hatchways are fitted, five steam winches, steam steering gear amidships, screw gear aft, one large multitubular boiler, and direct steam windlass. The boats are placed on beams overhead, and appliances will be specially fitted to comply with the Grain Carrying Act. Engines of the triple-expansion type are being supplied by Messrs. Blair and Co., Stockton-on-Tees. The hull and machinery have been built under the supervision of Mr. Maxwell Hill, Newcastle-on-Tyne. The vessel was named Ethel Radcliffe by Miss Clarice Radcliffe.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

*4th October*, 1894.

18,768. Parallel Ruler, W. H. L. Mariner.—(*W. Pigott, England*)
18,769. Roller Axle, J. Phelan, Mountrath.
18,770. Tires, H. Smith, Nottingham.
18,771. Twisting Fibrous Material, &c., C. Briggs, Bradford.
18,772. Railway Carriage Doors, T. Hobson, Manchester.
18,773. Mitre-cutting Machinery, W. G. Gass, Great Lever.
18,774. Hot-water Boilers and Pans, R. Crowther, Halifax.
18,775. Washing and Wringing Machines, J. Thornton, Halifax.
18,776. Water Regulator and Valve, H. Watson, Devizes.
18,777. Cycle Gear, T. Staines, J. Leadbeater, and A. Preston, Leeds.
18,778. Preventing Abstraction of Letters, H. Bessell, Bristol.
18,779. Improved Case for Pencils, J. Greaves, Oldham.
18,780. Stoppers for Bottles, E O. Loach, Birmingham.
18,781. Holder for Roller Window Blinds, H. P. Miller, London.
18,782. Door-closing Appliances, F. Dakin, London.
18,783. Indestructible Cone Castor, J. E. P. Proud, Dublin.
18,784. Trouser Guards for Cycles, G. D. Sampson, London.
18,785. Hat and Bonnet Protector, E. H. Höbling, London.
18,786. Hingeing the Picking Arms of Looms, J. Dodds Galashiels.
18,787. Non-twisting Ribbon Bodkin, E. Yates, Manchester.
18,788. Bag Fastenings, J. G. Beddoes and T. Allen, Birmingham.
18,789. Regulating Street Lights, M. Cummings, Glasgow.
18,790. Appliances for Clipping Hair, W. Bown, Birmingham.
18,791. Ammonia, W. McD. Mackey and J. F. Hutcheson, Glasgow.
18,792. Ammonia, W. McD. Mackey and J. F. Hutcheson, Glasgow.
18,793. Windows, H. Kerr, Glasgow.
18,794. Gas Fires, J. F. Brown, Glasgow.
18,795. Manufacture of Pneumatic Tires, P. Mercier, London.
18,796. Line Screens, G. G. Ward and M. Cohn, Belfast.
18,797. Fire-screen and Trivet Combined, S. S. Crisp and H. Grice, London.
18,798. Cork Separators, L. W. Sutcliffe, Manchester.
18,799. Attaching Pneumatic Tires to Rims, H. Kesterton, Manchester.
18,800. Valve Mechanism for Atmospheric Hammers, E. Skinner, Sheffield.
18,801. Construction of Trunks, &c., W. H. Eyre, Sheffield.
18,802. Letter Files, W. H. Morden, London.
18,803. Lock for Photographic Dark Slides, H. Ransom, London.
18,804. Beetle Trap, J. Pollock, London.
18,805. Lifts, &c., C. Musker and A. Musker, Liverpool.
18,806. Syphon for Water-closet Cisterns, C. H. Kitching, London.
18,807. Rotary Engine, L. Vojacek, London.
18,808. Cars for Roundabouts, F Collins and F. W. Savage, Birmingham.
18,809. Electric Storage Batteries, F. King, London.
18,810. Letter Cards, H. Jones, London.
18,811. Figures for Decorations, A. Tuck and W. H. Ellam, London.
18,812. Control of Lifts, J. S. Stevens and C. G. Major, London.
18,813. Rulers, A. Benda, London.
18,814. Electric Batteries, B. A. Balasny, London.
18,815. Steam Engine, J. D. Gray, W. B. Price, and A. Sharp, London.
18,816. Railway Car Wheels, J. Printz, C. F. Anderson, and V. H. Stromberg, London.
18,817. Lining for Hats, P. F. Allen, London.
18,818. Lamp Extinguisher, C. W. Cummings, Birmingham.
18,819. Typewriting Machines, C. Coote, London.
18,820. New Hoisting Apparatus, H. George, London.
18,821. Method of Stoppering Bottles, J. Spring, London.
18,822. Cutting Patterns, H. H. Lake.—(*C. E. Reed, United States*)
18,823. Ink-wells, H. H. Lake.—(*S. O. Johnson, United States.*)
18,824. Cartridges, J. G. Accles and J. Pinfold, London.
18 825. Rope Grips, J. Whitall, London.
18,826. Manufacture of Spoons, &c., A. Alexandre, London.
18,827. Tubes for Fishing Rods, &c., J. Thomas, London.
18,828. Apparatus for Condensing Fluids, E. Theisen, London.
18,829. Automatic Machine Gun, H. T. Ashton, London.
18,830. Fastening Spurs to Boots, H. Hardtke, London.
18,831. Manometers, W. P. Thompson.—(*The Maschinen and Armaturenfabrik vorm. C. L. Strube, Aktiengesellschaft, Germany.*)
18,832. Injector for Steam Engines, &c., L. Deprez, London.
18,833. Private Postcards, J. S. Morriss, London.
18,834. [No Application so numbered.]
18,835. Lining of Piece Goods, A. Kenealy, Watford.
18,836. Measurement of Piece Goods, A. Kenealy, Watford.
18,837. Water-tube Boilers, F. T. Marshall, London.
18,838. Water-tube Boilers, J. I. Thornycroft, London.
18,839. Lubricating Cups for Axles, C. W. Brown, London.
18,840. Fastening for Door Handles, G. McCarthy, London.
18,841. Game, W. May, London.
18,842. Preventing Destruction of Vessels by Torpedoes, D. Grant, London.
18,843. Seats for Cycles, G. Butwell and E. Roberts, Birmingham.
18,844. Treatment of Iron and Steel, &c., R. Stone, London.
18,845. Device for Securing Scarf Pins, A. Oldcorn, London.
18,846. Suspending Brushes in Bottles, G. Musgrave, London.
18,847. Sash Fastener, C. Patient, London.
18,848. Lamp Globe, W. T. Woolley, London.
18,849. Cooking Utensils, A. M. Pinks, London.
18,850. Fastening Boots and Shoes, W. E. Page, London.
18 851. Table Leg, &c., Castors, G. N. Witkowski, London.
18,852. Signalling Apparatus, L. B. Stevens, London.
18,853. Driving Gear for Cycles, G. White, London.
18,854. Ascertaining the Description of Leads, &c., C. W. G. Little, London.
18,855. Manufacture of Tickets, M. Vezzosi, London.
18,856. Locks, C. Shaw and F. J. J. Gibbons, London.
18,857. Construction of Hats, F. M. Rogers.—(*J. T. Todman, Ceylon*)
18,858. Umbrellas, Z. Wirt, London.

*5th October*, 1894.

18,859. Roundabouts, W. Parker, Bury.
18,860. Automatic Connection of Conductors, G. K. Chambers, London.
18,861. Construction of Padlock Cases, W. Wakelam, Willenhall.
18,862. Safety Appliance for Paraffin Lamps, F. A. Jackson, Leeds.

18,971. Centrifugal Machines, F. Hugershoff, Glasgow.
18,972. Nails and other Small Articles, G. B. Parkes, Birmingham.
18,973. Tapping Barrels, M. Morton and E. Morton, Birmingham.
18,974. Corrugated Plates for Floors, S. Strickland, Derby.
18,975. Weaving, C. Berisford, D. Birchenall, H. Berisford, W. Gorton, and C. Wood, Manchester.
18,976. Eyed Hooks, A. Morriss, Redditch.
18,977. Water Waste Preventer Cisterns, T. Atkins, Wolverhampton.
18,978. Candlesticks, J. and H. Smith and T. W. Hemingway, Sheffield.
18,979. Pneumatic Tires, J. Clinch, Manchester.
18,980. Detecting Imitation Diamonds, T. Thorpe, Whitefield.
18,981. Elevator Safety Appliances, S. G. Bennett, Smethwick.
18,982. Foot Brakes for Velocipedes, N. E. Craig, Plymouth.
18,983. Cannon or Guns, F. L. Tulip and J. H. Link, London.
18,984. Pneumatic Tire, E. J. Delday and H. C. Adams, Scarborough.
18,985. Covering for Football Fields, J. T. Seddon, Manchester.
18,986. Pencil-point Protector, M. Illfelder, Birmingham.
18,987. Hot-water Heating Apparatus, J. T. Softly, London.
18,988. Envelopes, E. S. and E. S. d'Odiardi and M. and E. Marx, London.
18,989. Scaffold-board Binder, J. M. Kimber, London.
18,990. Chandeliers for Burning Oil, D. Lambden, London.
18,991. Calendars, H. Grueber, London.
18,992. Softening Waters, H. L. Doulton and A. W. Manger, London.
18,993. Heating Calender Rollers, G. E. Payne, London.
18,994. Cycle Handles, M. B. Ryan, London.
18,995. Pen-wipers and Pincushions, W. H. Jackson, Liverpool.
18,996. Brush Mechanism for Dynamos, A. Ramsay, Liverpool.
18,997. Railway Carriage Windows, M. E. Elder and R. Bell, Liverpool.
18,998. Evaporating Soda Solutions, J. J. Crosfield and K. E. Markel, Liverpool.
18,999. Electric Fuses, W. P. Thompson.—(*La Société M. Gaupillat and Co., France.*)
19,000. Collapsible Boats, L. Höhnke, London.
19,001. Station Indicators, H. H. Leigh.—(*J. F. O'Brien, Canada*)
19,002. Hair Waving and Curling Pins, E. M. Gaskell, London.
19,003. Making Illuminating Gas, A. W. Pickering, London.
19,004. Burner Galleries of Lamps, O. Wollenberg, London.
19,005. Slate Frame, J. H. Rudolph, London.
19,006. Flue Cleaners, D. W. Dart, London.
19,007. Prevention of Lamp Explosions, J. Hall, London.
19,008. Railway Signalling, S. A. Varley and R. Burn, London.
19,009. Making Mosaic Floorcloth, W. Mather, London.
19,010. Making Mosaic Floorcloth, W. Mather, London.
19,011. Buffer Springs, A. G. and A. Spencer, London.
19,012. Mail-carts and other Vehicles, W. Legge, London.
19,013. Measuring Curved, &c., Lines, W. Ule, London.
19,014. Washing Fabrics, L. Crosset and J. Debatisse London.
19,015. Stovepipe Elbow Machine, R. W. Barker.—(*E. Blix and W. N. Gunderson, United States.*)
19,016. Window Fasteners and Latches, T. R. Wing, London.
19,017. Regulating Furnace Draughts, W. Magoolagham, London.
19,018. Rail Joints, J. W. Thomas, London.
19,019. Fastening for Boots and Shoes, C. H. Moulds, London.
19,020. Horse Collars and Saddles, D. S. Turner, London.
19,021. Velocipedes, J. Barratt, London.
19,022. Locks and Latches, W. Elder.—(*J. W. McKee, United States.*)
19,023. Toy, E. Savor, London.
19,024. Holder, &c., for Golf Clubs, T. Walters, London.
19,025. Material for Buildings, D. Young.—(*La Compagnie des Constructions Démontables et Hygiéniques, France.*)
19,026. Synchronising Attachment, J. W. Paige, London.
19,027. Album, J. Hutson.—(*E. W. Smith, United States.*)
19,028. Home Trainer for Cyclists, J. Hutson.—(*E. W. Smith, United States.*)

*8th October*, 1894.

19,029. Hydraulic Intermittent Motors, G. Threlfall, London.
19,030. Tubulous Steam Generators, E. White, Isle of Wight.
19,031. Horse Bridles, J. Emmett and H. Emmett, Dukinfield.
19,032. Ball and Socket Castor, &c., M. W. Dent, Blackburn.
19,033. Kettles for Lamps, J. E. Whiting, Bombay Presidency.
19,034. Braid or Binding, A. Nicholson and J. Hall, Leek.

19,035. Skirt Suspender, A. Nicholson and J. Hall, Leek.
19,036. Music Holder, S. Liddiard and T. E. Rickerby, Cheltenham.
19,037. Preventing Food Destruction, J. Pumphrey, Birmingham.
19,038. Traction Engine Wheels, F. J. Burrell, Thetford.
19,039. Self-basting Vessels, C. Livesey and E. W. Banner, Southport
19,040. Pantographic Carving Apparatus, W. Merl, Manchester.
19,041. Wagon Tarpaulin Cover, A. and W. Purvis, Glasgow.
19,042 Heat Non-conductors, J. C. S. McLay, London.
19,043. Inking Apparatus, A. Watkinson and F. W. Musgrave, London
19,044. Watch Keys G. Bottely, Birmingham.
19,045 Game, F. G. Paynter Newcastle-on-Tyne.
19,046. Regulating Water Supply, W. P. Theermann, Manchester.
19,047. Heating Soldering Irons, &c., G. Skinner, London.
19,048. Method of Braking Cycles, W. Saunders, Bristol.
19,049. Tops, J. Linkleter, Tynemouth.
19,050. Mounting Trays, J. C. Bailey and H. Podmore, Longport.
19,051. Frames for Sawing Machines, A. Smith, London.
19,052. Brakes for Wheeled Vehicles, W. E. Kay, Manchester.
19,053 Pneumatic Tire Inflators, H. Frankenburg, Manchester.
19,054. Chimney Water Heaters, &c., J. Syme, Monastereven.
19,055. Athletic Horizontal Bars, T. B. Sharp, Birmingham.
19,056. Curing Smoky Chimneys, W. J. and P. C. Wheeler, London.
19,057. Securing Fish-plates on Rails, J. T. Drew, London.
19 058. Pulley Blocks and other Lifts, W. T. Eades, London.
19,059. Button Fastener for Clothing, W. Halliday, London.
19,060. Window-blind Pulleys, A. F. Borradaile, London.
19,061. Cycle Handles, J. W. McEwen and T. B. Richards, London.
19,062. Uppers for Boots and Shoes, C. C. Eisenberg, London.
19,063. Blower for Fire-grates, R. Rose, London.
19,064. Milk Sterilisers, E. Leslie, London.
19,065. Producing Electricity, H. A. Tobias, W. H. Cadman, and R. J. Crowley, London.
19,066. Dough Mixing Machine, J. T. O'Callaghan, London.
19,037. Anchors, W. T. Honess, London.
19,068. Sel-acting Window Fastener, E. Seaman, London.
19,069 Hat Bands, F. W. and B. Franklin and P. E. Taylor, Birmingham.
19,070. Velocipedes, E. A. Jeffreys, London.
19,071. Tobacco Pipe, W. B Wallace, London.
19,072. Screw nuts, F. F. Ganly, Manchester.
19,073. Steering Lock, W. F. Taylor and G. Philpott, Croydon.
19,074. Method of Repairing Slating, R. J. Spreadbury, Bournemouth.
19,075. Jewel Fastenings, E. T. B. Woodley and H. E. Humphry, London.
19,076. Bicycles and Tricycles, A. L. Bricknell, London.
19,077. Knitting Machines, E. Buxtorf, London.
19,078. Stoppering of Bottles and the like, J. Jones, London.
19,079. Domestic Water Supply Apparatus, J. Bark, Liverpool.
19,080. Constructing Transparent Walls, G. Falconnier, London.
19,081. Writing Device for the Blind, D. Goldsmith, London.
19,082. Eating Buttered Bread, H. M. Conrad, London.
19 083. Small-arms. J. Courrier, London.
19,084. Bearings, H. Kirschbaum and A. Schnitzer, London.
19,085. Absorption of Gases by Liquids, A. Müller, London.
19,036. Implements for Cultivating Land, J. E. Ransome, London.
19,087. Apparatus for Purifying Sulphur, R. Tervet, jun., London.
19,088. Syphon Cistern, T. B. Jack, London.
19,089. Eye-shades, H. Reichardt, London.
19,090. Wedding Cake Boxes, &c., E. Guttentag, London.
19,091. Purification of Iron and Steel, S. Trivick, London.
19,092. Churns, T. Bradford, London.
19,093. Fastening Device, A. Wood, J. S. Walter, and W. M. Walter, London.
19,094. Fireplaces, J. Clemence, H. A. Leverett, and T. H. L. Bake, London.
19,095. Water-lift and Bucket, M. S. M. S. Bahadur, India.
19,096. Feeding Bottle, F. W. Edridge-Green, London.

*9th October*, 1894.

19,097. Garments, A. G. Brookes.—(*M. M. Dunn' United States*)
19,098. Fuses for Projectiles, A. G. Brookes.—(*W. J. Smith, United States*)
19,099. Water-level Indicator, R. H. N. Lindley and F. J. Mudford, London.
19,100. Cots, J. E. Hoskins, Birmingham.
19,101. Stopper or Plug for Bottles, A. D. Jackson, Portsmouth.
19 102. Artificial Lighting Apparatus, G. Houghton, London.
19 103. Rubber Hose, T. Sutcliffe, Lancashire.
19,104. Dish for Holding Meat, &c., F. G. Wallis, Kettering.
19 105. Shield for Protecting Garments, F. Hughes, London.
19 106. Making, &c.. Chains and Bridle Fronts, J. Richards, Birmingham.
19 107. Framings of Velocipedes, R. F. Hall and R. H. Anderson, Birmingham.
19,108. Simple Crank Motion, H. W. Nickson and A. E. A. Edwards, Birmingham.
19,109. Non-conductor of Heat, C. Clarke, Birmingham.
19,110. Wheels for Railway Vehicles, J. A. Craven and T. Foster, Sheffield.
19,111. Toy Saving Banks, R. B. Roll, South Shields.
19,112. Oil Motor Engines, D. Clerk and F. W. Lanchester, London.
19,113. Paper for Catching Flies, &c , J. W. Dougal, Glasgow.
19,114. Lifting Apparatus, R. Middleton, Leeds.
19,115. Broiler, C Coleman. Welford, near Rugby.
19,116. Woven Belting, W. M. Martin, Glasgow.
19,117. Fire-extinguishing Apparatus, H. B. Barlow.—(*C. R. Macomber, United States*)
19 118. Employe's Time Recorder, J. S. Morse, London.
19,119. Pulley Casing for Window Frames, J. H. Foote, London.
19,120. Clamps for Pipes, C. Hall, London.
19,121. Electric Arc Lamps, J. E. Woolverton, Glasgow.
19,122. Sewing Machines, A. Anderson.—(*The Singer Manufacturing Company, United States*)
19,123. Letter Files, W. O. Gottwals, Canada.
19,124. Letter Files, W. O. Gottwals, Canada.
19,125. Knitting Machines, G. W. Beach, London.
19,126. Construction of Golf, &c., Bats, B. J. Maloney, Edinburgh.
19,127. Production of Ozone, J. T. Donovan and H. L. Gardner, London.
19,128. Hydrometers, W. Hood, London.
19,129. Railway Signalling Apparatus, A. G. Evans, London.
19,130. More Perfect Combustion of Coal Gas, R. H. Courtenay, London.
19,131. Adjusting the Seats of Carriages, F. W. Milligan, London.
19,132. Brick Kilns, W. A. Wilford, Birmingham.
19,133. Novel Eyed Fly Holder, J. Richardson, London.
19,134. Sewing Machines, W. H. Harrop, London.
19,135. Tie, C. Cox, London.
19,136. Boots, C. Cox, London.
19,137. Toy Shooting Galleries, A. W. Carley, London.
19,138 Lift for Sashes of Greenhouses, A. C. Bright, London.
19,139. Manufacture of Socks, H. T. Hines, London.
19,140. Sprocket Wheels, P. D. Murphy and E. Kolb, London.
19,141. Apparatus for Cable Tramways, E. Neil, London.
19,142. Hat-stretching Machines, G. Atherton.—(*R. Eickemeyer, United States.*)
19,143. Machines for Dressing Type, W. W. Farmer, London.
19,144. Securing the Corners of Boxes, A. A. Wood, London.
19,145. Valves, H. H. Lake.—(*F. C. Weir, United States.*)
19,146. Mechanism for Looms, J. T. Bolton and G. Grime, London.
19,147. Advertisements, G. F. Zimmer and J. Hutson, London.
19,148. Exhibiting Figures, Pictures, &c., M. Vollmer, London.
19,149. Fastenings for Trousers, &c., R. L. Weiss, London.
19,150. Electro-deposition of Metals, W. H. Beck.—(*C. R. Fletcher, United States.*)
19,151. Fastenings of Brooches, Pins, &c , R. Synge, London.
19,152. Speed Apparatus for Swimmers' Use, L. Pedrazzolli, London.
19,153. Spinning Mechanism, J. Neale and W. O. Shadbolt, London.
19,154. Tobacco Pipes, W. E. Trott, London.
19,155. Arc Lamps, A. J. Boult.—(*P. Laminne, Belgium.*)
19,156. Pencil Sharpener, W. P. Thompson.—(*J. Deutschbein, Germany.*
19,157. Electric Battery Plates, H. Le R. Bridgman, London.
19,158. Railway Fences, &c., A. Stevenson, Liverpool.
19,159. Pneumatic Tires, G C. Nesbitt, London.
19,160. Harvesters, W. P. Thompson.—(*B. F. Stewart, United States*)
19,161. Calking Vessels, A. J. Brooks, London.
19,162. Cotton Gloves, &c., J. E. Cowell.—(*G. Neuhaus, Germany*)
19,163. Calendar Clocks, C. W. Feichtinger and S. Shearer, London.
19,164. Oil Stoves, E. Rippingille and W. Porter, London.
19,165. Apparatus for Cutting Coal, J. B. Alliott, London.
19,166. Treating Peat, A. McLean, London.
19,167. Hooks and Eyes, A. Clorius and C. Schwartz, London.
19,168. Tooth Brushes, H. Besson and G. H. Kent, London.
19,169. Preventing Incrustation in Boilers, G. L. F. Edeline, London.
19,170. Apparatus for Rousing Liquors, H. Prince, London.
19,171. Textile Fabrics for Pneumatic Tires, J. F. Palmer, London.
19,172. Retaining Corks in Bottles, J. W. and F. H. Butler, London.
19,173. Tree for Boots, The Honourable R. T. D. Brougham, London.
19,174. Treatment of Natural Phosphates, D. Levat, London.
19,175. Paper Coated with Celluloid, A. Gray, London.
19,176. Telephone Annunciators, L. M. Ericsson, London.
19,177. Apron Holders, L. Byron-Peters and W. McLaren, London.
19,178. Means for Cleaning Rice, &c , E. Kallsen, London.
19,179. Gas Chimney Protector, F. A. Seigel and F. A. Solbrig, London.
19,180. Fireproof Floors, C. A. Balph and E. P. S. Wright, London.
19,181. Submerged Roads, &c., M. A. de Palacio, London.
19,182. Pipes, &c., for Water-closets, H. I. Dakin, London.
19,183. Lathing, E. F. Stimson, London.
19,184. Electric Heaters, J. R. Davis, London.
19,185. Electric Switches, F. Stevens and R. R. Kesteven, London.
19,186. Electric Fire-alarms, L. G. Rowand, London.
19,187. Alkyl-ethers, J. Y. Johnson.—(*C. F. Boehringer and Soehne, Germany.*)
19,188. Lactyl-*p*-Phenetidine, J. Y. Johnson.—(*C. F. Boehringer and Soehne, Germany*)
19,189. Chlorate of Soda, T. T. Best and G. Brock, London.
19,190. Dust-trap, W. H. Steel and W. H. Steel, London.
19,191. Securing Battery Wires, F. A. and N. von Alimonda, London.
19,192. Fixing Fastenings for Boots, J. G. Paterson, London.
19,193. Floats for Fishing, &c., J. R. Richardson, London.
19,194. Brace Buttons, J. O'Rorke, London.
19,195. Securing Laces of Boots, &c., W. Thomas, London.
19,196. Suspending Hooks, R. D. Moody, London.
19,197. Railway Car Couplings, R. D. Moody, London.
19,198. New Match Holder, J. Richter, London.
19,199. Fermenting Apparatus, A. D. Currie, London.
19,200. Setting Printing Type, G. C. Downing.—(*J. Salomon, Germany.*)
19,201. Distributing Printing Type, G. C. Downing.—(*J. Salomon, Germany.*)
19,202. Syruping Aerated Liquids, E. S. Chavasse, Birmingham.

*10th October*, 1894.

19,203. Pneumatic Tires, T. R. Piner, London.
19,204. Cleansing and Polishing Soap, C. J. Goodland, Bridgwater.
19,205. Self-closing Bag Frame, P. B. Hollick, London.
19,206. Graining Machine for Oil Colours, H. J. Probyn and T. Wood, Gloucester.
19,207. Releasing the Backs of Watches, J. S. Wilday, Birmingham.
19,208. Pneumatic Tires, A. Maltby, London.
19,209. Cycle Gear, F. W. Briggs. London.
19,210. Splitting Cottar Pins, T. W. Lench, M. A. and T. Robson, Birmingham.
19,211. Profiling Machines, R. F. Hall and C. Taylor, Birmingham.
19,212. Commercial Blotting-pad, T. M. Markham, Manchester.
19,213. Chimney Ventilators, R. Morris, Gateshead-on-Tyne.
19,214. Cranes, B. B. Dadley, London.
19,215. Constructing Entree Dishes, R. Stevenson, Sheffield.
19,216. Lathes for Polishing, &c , A. Davidson, Sheffield.
19,217. Pneumatic Tires for Carriages, J. Hopper, London.
19,218. Flexible Hose Pipe, E. L. Pease, Stockton-on-Tees.
19,219. Fastening for Hats, W. Stevenson, Nottingham.
19,220. Electric Ship Logs, W. D. Whyte and D Muirhead, Glasgow.
19,221. Protecting Pneumatic Tires, J. Alverti, Cheshire.
19,222. The Safety Hair-curling Pin, R. Glossop, Redditch.
19,223. Photographic Plate Carriers, A. J. Mason, Birmingham.
19,224. Billiard Table Cushions, J. R. Jackson, Manchester.
19,225. Boots and Shoes, R. W. and L. H. Bateman, Halifax.
19,226. Machinery for Dyeing Yarn, W. H. Thorpe, Halifax.
19,227. Flushing Appliances, J. Shanks and A. Burnside, Glasgow.
19,228. Gas Engine, &c , Connecting-rods, J. Mills, Manchester.
19,229. Glove Fastener, K. Gengnagel, St. Leonards-on-Sea.
19,230. Vehicle Wheel Construction, H. H. Mulliner, Birmingham.
19,231. Supporting Gas, &c., Shades, W. Beal, Birmingham.
19,232. Air Valves for Pneumatic Tires, J. Cockburn, Glasgow.
19,233. Heating and Ventilating Radiators, J. Keith, Glasgow.
19,234 Hot Water Boilers, J. Keith, Glasgow.
19,235. Dyeing Mixed Woven Fabrics, T. Ingham, Manchester.
19,236. Water-tube Boilers, J. A. McKie, Glasgow.
19,237. Sealing Jars, R. Karges, Manchester.
19,238. Anti-slipping Tire-grappler, W. Clark, Newcastle-on-Tyne.
19,239. Movable Calendar or Date Case, H. Vereker, Glasgow.
19,240. Spring Mattresses, O. Ransford, Glasgow.
19,241. Collapsible or Folding Wardrobes, W. H. Vaughan, London.
19,242. Collapsible, &c., Furniture, W. H. Vaughan, London.
19,243. Preparation for Curling Hair, G. H. Hill, London.
19,244 Mudguards for Cycles, W. Cunningham, London.

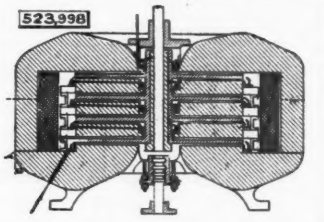
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**523,998.** Dynamo-electric Machine, *G. Rennerfelt, Lynn, Mass.—Filed March 6th*, 1894.

*Claim.*—(1) The combination of a magnet with a divided core, a series of rotating conductors interposed between the parts thereof, and means for electrically connecting said conductors in series, substantially as described. (2) The combination of a magnet with divided core, a series of rotating conductors interposed between the parts thereof, and means for electrically connecting said conductors in series, consisting of a series of suitably connected liquid collectors, substantially as described. (3) The combination of a magnet with a divided core, a rotating conductor interposed between the parts thereof, and annular vessels containing mercury suitably arranged for collecting the current generated on said conductor, substantially as described.

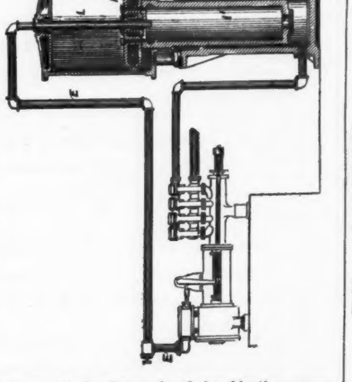
523,998



**524,013.** Pressure Accumulator, *C. C. Worthington, Irvington, N.Y.—Filed February 26th*, 1894.

*Claim.*—The combination with a steam engine, of a steam accumulator forming part of the steam connections between the steam supply and engine, and means for varying the supply of steam to the engine in accordance with the movement of the accumulator piston, substantially as described. (2) The combination with a pressure accumulator having a differential piston I, I′, the piston I′ being hollow, of perforated exhaust pipe L passing through the piston I into the hollow piston I′, closed pipe O in said hollow piston I′, and a non-heat-conducting packing about said pipe O, substantially as described. (3) The combination with a pressure accumulator connected with an elastic fluid supply, of pipe E connecting with the accumulator chamber by a series of openings arranged in the line of movement of and opened and closed by the accumulator piston, substantially as described. (4) The combination with a pressure accumulator connected with an elastic fluid supply, of pipe E, and exhaust pipe L connecting the accumulator chamber with the pipe E and having a series of openings opened and closed by the movement of the accumulator piston, substantially as described. (5) The combination with a pressure accumulator connected with an elastic fluid supply, of pipe E, and perforated exhaust pipe L in the accumulator chamber connecting with the pipe E and passing through the accumulator piston, whereby the perforations in the pipe are opened and closed by the piston, substantially as described.

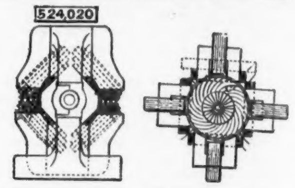
524,013



**524,020.** Dynamo-electric Machine, *R Eickemeyer, Yonkers, N.Y.—Filed October 7th*, 1891.

*Claim.*—(1) In a dynamo-electric machine, the combination with an armature, of separate electro-magnets arranged with their similarly polarised cheeks closely adjacent to each other, but separated by narrow spaces, parallel with the armature winding, and counterfield coils in circuit with the armature winding, but receiving electric current, in a direction opposite to that in the adjacent portion of said winding, and having portions of said coils located at said spaces parallel with said adjacent portions of the winding, the air spaces affording resistance in those magnetic circuits which are induced by said adjacent portions of the armature winding, and the counterfield coils inducing a magnetic flow, opposite to that which is induced by said portions of the armature winding. (2) In a dynamo-electric machine, the combination, substantially as hereinbefore described, of an armature, separate U-shaped electro-magnets, each having its own field coil or coils, and provided with appropriate cheek pieces, and having the several similarly magnetised cheeks located closely adjacent to each other, but separated by air spaces parallel with the armature winding, and a counterfield coil on each magnet, in circuit with the armature winding, and having portions thereof located in said spaces, and parallel with the armature winding.

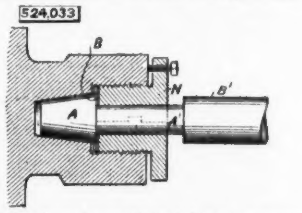
524,020



**524,033.** Device for Securing Piston-rods to Crossheads, *C. G. Turner, Wilmington, Del.—Filed May 3rd*, 1894.

*Claim.*—The combination of a crosshead having a socket therein, of a piston-rod having a head A and a reduced portion A¹ behind the head whereby shoulders B and B¹ are formed, a nut N divided into two or more segmental parts adapted to embrace the reduced portion of the rod and engage with threads on the crosshead so that by screwing or unscrewing the nut the head on the rod can be forced in or out of the socket in the crosshead.

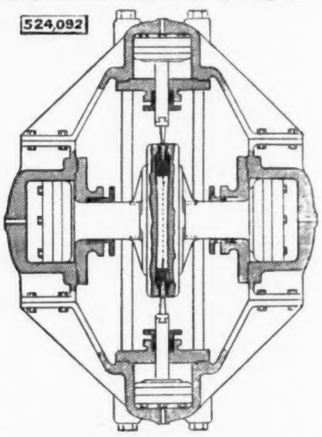
524,033



**524,092.** Machine for Making Axles, *C. Mercader, Braddock, Pa.—Filed July 6th*, 1893.

*Claim.*—In a machine for making axles, the combination with a pair of matrix dies for forming and clamping the axle blank, of two piercing dies at right angles to the matrix dies and arranged to enter the open ends thereof, and force the metal laterally to form the collars, and mechanism for operating said dies, substantially as described.

524,092



**524,129.** Skate Blade and Art of Manufacturing Same, *T. W. Bryant, Torrington, Conn—Filed March 24th*, 1894.

*Claim.*—(1) A skate blade having a cold rolled polished outer skin of metal, which is exceedingly thin, formed on its opposite sides, which serve as cutting edges for the intervening metal of the tread, substantially as set forth. (2) The method of manufacturing skate blades, which consists in cold rolling a metal plate, thereby forming thereon an exceedingly hard and smooth outer skin, then cutting or punching the blank from the plate, and finally finishing the tread by grinding, substantially as specified.

## PIVOTED ARCHED BRIDGES.

The general or abstract principles which govern and distinguish any particular type or design of engineering structure are theoretically immutable. Among the more universally applicable of these may be mentioned the laws of the lever, the relation between action and reaction, the resolution of forces, the pull in tension, and the thrust in compression. In practice, that is, in the designing and actual construction of girders, bridges, trusses, and roofs, these general principles are nearly always more or less liable to modification. In fact, there are not wanting instances in which the original principle has been subjected to so many alterations, and even violations, that it would puzzle the most experienced professional expert to determine to what especial type the example does belong. Omitting abnormal and exceptional cases of this nature, it may be nevertheless fairly inferred—and we shall adduce ample evidence of the truth of our remarks—that the principle or type of design which, while retaining its own peculiar characteristic, yet admits of the greatest amount of modification, will be more generally adopted than others. In a word, the principle which is susceptible of the greatest adaptability to different purposes, or to the same purpose, under different conditions, will, without any metaphor, rank as the survival of the fittest.

There are, without referring to simply solid girders or examples of a primitive and insignificant description, two types of design which will, we submit, sufficiently support the inference we have drawn. They are the tubular and the suspension bridge, the former being at present absolutely obsolete, and the latter in a fair way to become so. It is a little curious that the Britannia tubular bridge was, with the exception of two or three imitations on a smaller scale so far as length of span was concerned, the first and last of its kind. It was certainly not due to any defect or failure of the structure itself, for at the present day within its iron walls run the heaviest and fastest trains of the London and North-Western Railway. The cause of its disuse is due to the reasons we have already alleged. Its sphere of action was too limited. Its principle was not capable, consistently with collateral unavoidable conditions, of adapting itself to the more general requirements of bridge construction, and engineers consequently abandoned it. The suspension bridge, so far as mere length of span is regarded, stands on a more favourable footing; but, on the other hand, it is completely deficient in those very necessary qualities for which the tubular type is pre-eminently distinguished. Flexibility is the essence, the very life of the suspension principle, and all endeavours to obviate it, that is, to so modify the principle as to render it capable of being applied to purposes where the maximum amount of rigidity is indispensable, have proved abortive, as in Lambeth Bridge and other structures of a similar character. Apart from this incurable defect, suspension bridges are fast being superseded, even in their own country, by the modern cantilever or continuous girder bridges, more elegantly termed by French engineers *poutres équilibrées*, and we say these things while taking account of the fact that under exceptional circumstances, as at Niagara, the suspension principle has been used in railway bridges.

It does not necessarily ensue that an alteration or innovation in the design or construction of a bridge interferes in any degree with its governing principle. It may, on the contrary, conduce to a more accurate application of it, and enable a more exact determination of the nature, amount, and direction of the resulting stress to be arrived at. It is admitted in connection with the subject of our article, that the pivoting or hinging at one or more points of the ribs of arched bridges tends to bring about—theoretically—a more accurate adjustment of the resulting stresses; but whether in actual practice this desirable result is fully obtained, is not by any means a matter of absolute certainty. At any rate, we shall quote some very recent examples, in which both solid and open-web arched ribs are fixed at both springings, continuous over or through the crown, and as rigid throughout as a stone arch, making due allowance for the difference of the material employed. There is a difference between the theoretical linear arch, and the practical application of it in modern iron and steel structures of the same form. While fully able to sustain all the compressive stresses to which it is subjected, the linear arch is powerless to resist moments of flexure. On the other hand, the iron or steel arch not only withstands successfully both these descriptions of stresses, but under peculiar conditions, those of a tensile character as well.

A distinction must be drawn between a solid and an open web arched rib, with respect to the number of pivoting points permitted. We have not been able to find any example of a plain solid arched rib hinged or discontinuous at the crown, and at the same time hinged or pivoted at the springings also. On the other hand, there are numerous instances in which braced arches which are not under the same conditions as the solid arch, or arch proper, or generally arches with open webs, are hinged both at crown and at each of the springings. The practice among engineers of hinging the ends of solid arched ribs is comparatively very modern. We may look in vain from Pimlico railway bridge, old Vauxhall, Westminster, Blackfriars, down to Southwark, all of which are solid arched ribs, for any such evidence of discontinuity. Telford, also, in the Tewksbury bridge, built over the Severn, having a span of 170ft., constructed the cast iron arched ribs solid throughout. In France the largest cast iron arched bridge, the Pont Saint Louis, has a span of 210ft., or 30ft. less than the centre span of old Southwark. It carries a public road over the Seine, and is continuous at the crown and fixed at the springings. In the two railway bridges over the Trent, of 200ft. each in span, the ends of the cast iron ribs are rounded, and fit into shoes; but they do not turn at the joints, and the arches rise and fall with the varying temperature. It is no doubt due to the fact that the adoption of braced and open web arched ribs in the construction of bridges did not take place until long after the solid arch was extensively employed, that we find the newer type more generally hinged or pivoted than the older.

All open web arched ribs may be subjected to three particular modes of treatment. They may be hinged at both the springings and at the crown also, a condition to which we have already stated solid ribs have not yet been rendered amenable. Secondly, they may be pivoted or hinged at the ends or springings only and continuous at the crown; and thirdly, they may, as in the examples alluded to, be continuous at the crown and fixed at the abutments, that is, fixed throughout. Examples of open web arched ribs are not very numerous, and those of the braced form still less so, although there is no doubt considerable economy in the employment of that particular design. When an arched rib is pivoted at both abutments, and at the crown as well, it obviously can be fairly represented by a pair of curved rafters braced together so as to constitute an ordinary triangular roof truss, held together at the ends by the thrust against the abutments in the place of the usual tie. Thus, the arch exists really more in form than in principle. The stresses can then be ascertained without any great difficulty, so long as there are not more than two unknown forces acting at any apex. In the event of redundant members, whether at the abutments or elsewhere, one set of the diagonals must be discarded, or the calculation of the stresses becomes well nigh impracticable. When the bracing is correctly arranged, which is not always the case, the centre of pressure in an arch, hinged at crown and abutments, will, under any condition of loading, pass through the three given pivoted points, and will thus accurately determine the position of the polygon of equilibrium. The absolute stresses will depend, as in other examples of similar construction, upon the nature, whether symmetrical or unsymmetrical, live or dead, and the amount of the loading. If the load were completely uniform in character, little or no bracing would be required, as occurs in a bowstring girder under similar circumstances. The effect of contraction and expansion in this type of braced arch is simply to produce a rise and fall at the crown. There is an example of a wrought iron braced arch of this description about 70ft. in span in Philadelphia, in America.

Instances in which the second mode of treatment is adopted, or that in which the arch is hinged at the springings, and continuous at the crown, form the most numerous of the three, in both railway and road bridges. The accurate determination of the stresses in this case becomes exceedingly difficult, although approximate calculations can be arrived at, sufficient for all practical purposes. Examples of braced arches of this system are to be found in a railway bridge over the Theis, consisting of eight arches of 136ft. in span each, and in the Paris and Creil railway bridges. Again, the Douro Bridge, which is a lattice arch of 525ft. span is continuous at the crown and pivoted at springings, so also is the railway bridge over the Rhine at Coblentz. The Harlem River structure in America is also a fine example, with a pair of solid cast steel arched ribs of 510ft. each, provided with steel pins to pivot on over the piers. As a recent instance, which is barely three years old, the "Pont du Midi" may be quoted. It consists of three solid steel arches, of which the centre span is 225ft. At the centre the depth of the rib is 3ft. 6in., and at the springings 4ft 9in., where it rests upon steel pins nearly 8in. in diameter. When the ends of an arch are hinged at the springings, the points of support are supposed to be situated at the mass centre of the cross section of the rib, and the end sections must pass through these points, and if the arch be free to move at those points the bending moments vanish.

In the third category are to be included all those examples of arched ribs, whether of the open or solid web system, which are fixed both at the abutments and continuous at crown; in fact, as already stated, fixed throughout. While this case presents the greatest difficulty in the exact determination of the stresses, yet it affords all the advantages which can be derived from the strength or elasticity of that particular form of rib. Existing examples, some of very old and some of very recent date, point incontestably to the fact that solid, substantial, broad bearings have answered well and sufficiently for their work, and without denying the merits, chiefly with regard to an assumed economy of material, claimed for the pivoted system, it is doubtful whether these merits are equally conspicuous in the actually constructed design. As a convenient example we may select the lattice arched rib, 240ft. in span, carrying the roof of the terminal station of the Midland Railway at St. Pancras. It is true that this arch is self-contained, but if ever an open web arched rib was securely fixed at the ends, this one ought to be, for it is solidly riveted to heavy cross girders which pass underneath the platforms and permanent tracks, and constitute a subterranean tie to the whole of the roof ribs. The bridge over the Mississippi at St. Louis, and another over the Elbe, near Hamburgh, on the Paris and Hamburgh line, are without any articulations, as is also one built only two years ago over the Cerveyrette at Briançon in France. These arched ribs have a span of 169ft., are 2½ft. deep at the crown, and 6½ft. at the springings. As a concluding instance the two bridges erected last year over the Rhone, at Lyons, may be quoted, having a central span equal to 221ft. Each span is composed of eight arched ribs of steel of a box section, and each rib abuts on cast iron skewbacks by means of three pins, one of which is fixed in the line of the axis of the rib, and each of the others takes up the bearing at the upper and lower booms respectively. A sheet of lead ⅛in. in thickness was placed between the stonework and the cast iron skewback. It is stated, with respect to these two bridges, that 30 per cent. of the metal in them would have been saved if they had been hinged both at the abutments and crown, and 10 per cent. if at the former points only. This great sacrifice, which must have been a sore trial to the engineer, was incurred on account of fear of excessive vibration.

The stresses resulting from the effects of temperature upon arched ribs solidly fixed, as just described, are very considerably greater than in articulated ribs; and there is no doubt that it is in great measure with the object of reducing these that pivots have been introduced. Some engineers have estimated this proportion as high as six to one, and attended with a corresponding augmentation of the stresses in the web. On the other hand, although the fixed arch is subjected to a greater shearing stress near the abutments than the articulated example, it has to carry less at the centre, and requires a smaller sectional area in the booms or chords. It also possesses the great advantage claimed for the *poutre equilibrée*—that is, of transferring a large portion of the working load to or near to the abutments, and thus relieving the more central portion of the arch. We think, from the examples up to date we have adduced, it may be fairly concluded, as has been the object of our article, that while engineers possibly may agree respecting the abstract theoretical economy of the articulated rib, they are by no means prepared to adopt it to the total exclusion of the fixed type.

## A MODERN NAVAL BATTLE.

The following description of the great Japanese naval battle, given by a young Englishman, who was the supervising engineer on the Chinese cruiser Yang-Wai, and who went to the United States for treatment for injuries he received in the battle, appears in the United States *Army and Navy Journal*. Our readers must take the sensational statements for what they are worth. What is said about the surgeon's treatment of the wounded must be a mistake. The Yang-Wai is a cruiser of 1350 tons displacement, carrying two 25-ton Armstrong 10in. guns, and four 4·7in. quick-fire guns, besides smaller ordnance. She was launched in 1881. It was quite impossible that she would have attained a speed approaching 20 knots, as her maximum trial trip speed was but 16 knots:—

The Chinese Admiral received word from Pekin, July 12th, to watch the Japanese without making any aggressive move. The Yang-Wai was accordingly detailed to proceed to sea and keep an eye on the Japanese. She overtook the Japanese fleet eighty miles to the southward, passing through their lines in defiance of the Japanese Admiral's orders to stay away, and making a spurt, led the Admiral's flagship a swift race. When the rest of the fleet had been left out of sight in the distance, the Yang-Wai suddenly turned and planted a 10½in. shell out of a 38-ton forward gun in the port bow of the Metsuchima. It tore an enormous hole in her upper deck, and disabled three of her 8in. guns. Passing the Metsuchima on the return tack, her secondary battery was fired broadside into the Japanese vessel, and as she passed astern her 25-ton gun came to bear on the Japanese vessel's after barbette. Several of the Japanese guns were disabled before she was able to return the fire.

Some clever manœuvring followed, and both vessels proceeded to pour broadside after broadside into each other. The battle lasted from 11 30 o'clock in the morning until three in the afternoon. After the Yang-Wai had been disabled, with the exception of the big gun forward, she managed to cripple her opponent by a shot which struck the conning tower of the Japanese vessel, killing the Japanese admiral and several of his officers. This completely disabled the Japanese ship.

Shortly after the Metsuchima ceased firing, and while we were busy ascertaining the extent of our own injuries, we sighted the other Japanese vessels approaching, and the Yang-Wai's commander gave orders to make a run for it to Weipaiwei.

The scene aboard the Yang-Wai after she had withdrawn from the unequal conflict was simply hideous. There was but one gun left in fighting trim, and that being the big bow gun, it was useless in flight. The six Japanese warships pounded away at us as we ran, and we were devoutly thankful that our speed was great enough to soon get out of range. The Yang-Wai was simply a floating wreck. Above the water-line everything was ruin. The pilot-house, bridge, and conning tower had gone early in the fight; the boats were shot into splinters, and the superstructure was in a hopeless, shapeless tangle. The funnel had been shot away to within 4ft. of the deck, and as we were running under forced draught we rigged a jury stack of sheet iron and canvas supported by a derrick. A hose was kept playing constantly on this makeshift funnel to prevent it from taking fire or melting.

The captain directed his crippled craft from a jury bridge of empty liquor casks and soap boxes, using a boat's compass, as the binnacles had been shot away. The masts were gone and the rudder too, but steering with the twin screws was comparatively easy. The Yang-Wai had been in commission nine years, but we got twenty knots out of her, or two knots better than she did on her trial trip.

The junior officer was sent down to take charge of the stokeholds, where naked coolies were shovelling coal for dear life. He had several cases of gin, which he gave to the sweating stokers as often as they asked for it. In one hand he held a thick club made of a section of thick rubber belting, and whenever a man lagged he beat him with it until he picked up his shovel again. The draught that was produced was so fierce that a continuous sheet of flame poured from the jury funnel. Below, the cruiser was a huge butcher shop. Holes 14ft. square yawned in her side, marking the place where the Japanese shells had entered. These war engines in bursting had blown the upper deck into fragments. On the main deck was the worst of all. It was simply a lake of blood fully an inch deep in the shallowest part. Writhing in this and floating in the deeper parts were heads, arms, and legs, with here and there the fragment of a man still alive tangled among the fragments of timber and steel torn from the cruiser's sides and decks. There were only two white men aboard the cruiser, myself and the surgeon.

As soon as the vessel was out of danger from the shells of the Japanese gunboats, he and I, with a corps of the surgeon's assistants, set about clearing up the terrible mess on the main deck.

Wherever we found a man hopelessly wounded, the surgeon gave him instant relief from his agony. He carried an atomiser filled with prussic acid, and as soon as his hasty examination of a hopeless case was finished, he sprayed the poison into the man's mouth and nostrils. The dying men craned their necks forward eagerly in their desire to escape from the torture they suffered. There were very few of the wounded who were not put out of their misery by the surgeon's atomiser.

One of the most distressing features of an engagement like this is the terrific noise aboard a modern man-of-war fairly in action. The Yang-Wai fought all the time with one screw turning slowly, her fires raked clean, and the steam blowing off like the shrieking of a gale. The scream of the shells, the thud and the vibration as they struck the cruiser, the terrific roar as they burst, and the deafening noise and concussion of our own guns, made it utterly impossible for anything else to be heard aboard the vessel. To my dying day I shall remember that July 12th, and, most of all, the horrible noise and the scene on the bloody main deck. We broke the record, I think, on our run to Shanghai, where we arrived at four o'clock on July 13th.

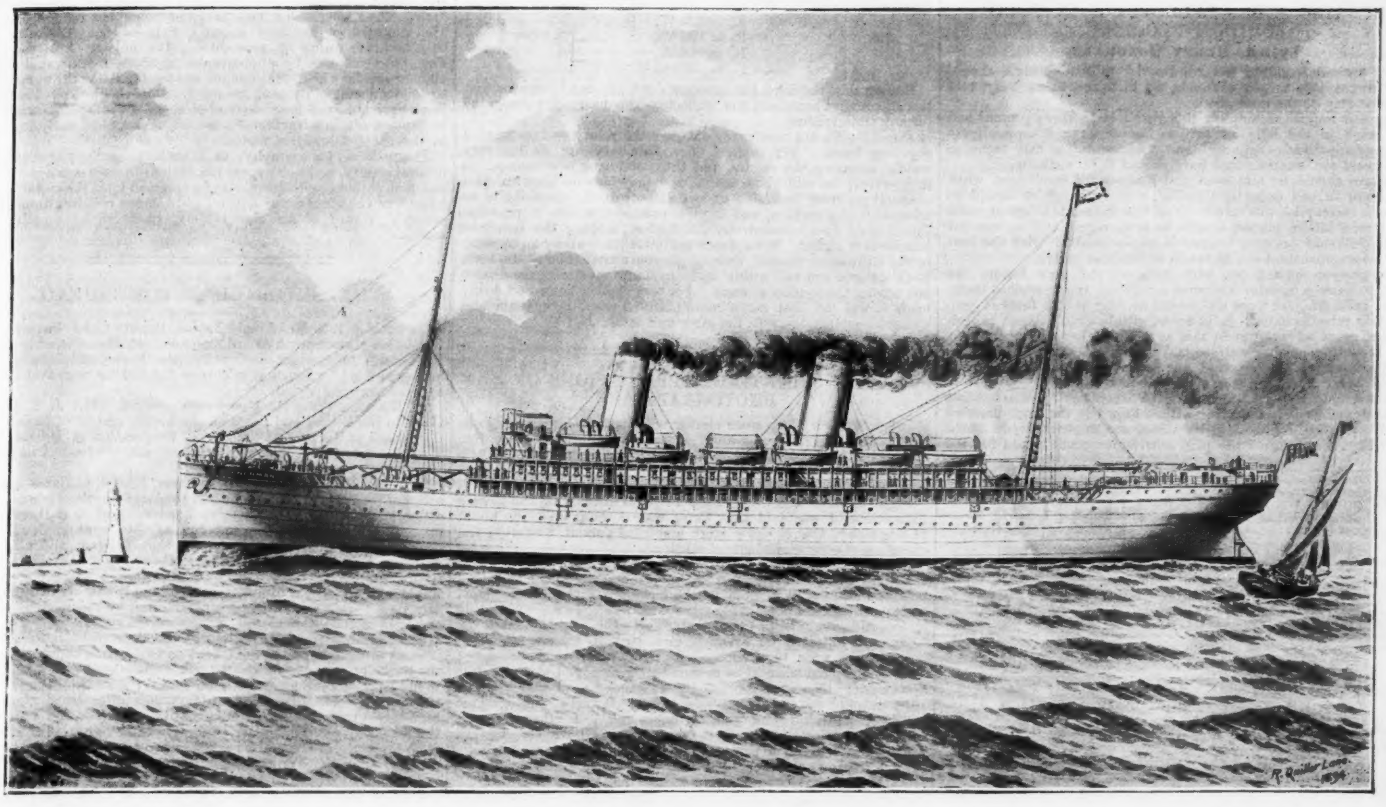
# THE UNION STEAMSHIP NORMAN

MESSRS. HARLAND AND WOLFF, BELFAST, BUILDERS AND ENGINEERS



## THE NEW SOUTH AFRICAN STEAMER NORMAN.

We illustrate above the latest addition to the Union Steamship Company's fleet. In our issue of July 27th we gave an illustration of this vessel as she appeared on the stocks, at the same time giving particulars. Consequently little remains to be said. We may, however, repeat that her length between perpendiculars is 490ft.; moulded breadth, 53ft.; depth, 37ft. 6in.; and gross tonnage 7392. The steamer leaves Southampton on her first voyage on the 10th November, and will leave Cape Town homewards on the 19th December. We anticipate that by early record breaking, she will prove herself worthy of her eminent builders, Messrs Harland and Wolff.

## THE BREWERS' EXHIBITION.

The sixteenth annual exhibition of machinery, appliances, and produce used by brewers, maltsters, distillers, &c., was opened at the Agricultural Hall on Monday, the 22nd inst., and will close to-morrow evening. As this Exhibition is always held in the same building, many exhibitors retain the same position year after year; and this is perhaps one reason for the creditable state of advancement on the opening day. With few exceptions all were ready, and the machinery at work; and, judging by the attendance on that day, the show is likely to be very successful. The principal feature this year is the number and variety of cooling apparatus; but other necessary appliances for breweries, from well-sinking to cask-making and cleaning, are all represented; and the manufacturers of aërated water machinery are increasing in number and in the size of their largest machines.

On entering the main building, the first stand observed is that of Messrs. Le Grand and Sutcliff, who exhibit the various appliances for sinking Norton's Abyssinian tube wells. They also show cores from diamond and steel drills, from depths up to 1100ft., and a set of boring tools up to 17½in. diameter. Another of their exhibits is a "spun" gun-metal pump-barrel for deep well pumps. This barrel is 12in. diameter; the spinning process is intended to ensure a homogeneous metal, free from flaws or air bubbles.

Well-sinking machinery is also shown by Messrs. C. Isler and Co., of Southwark, who have an interesting collection of cores from diamond drills, ranging from 1½in. to 9in. diameter. In a perforation of the smaller size through oolite, the rate of progress was only 1ft. per day, whilst a 9in. boring was put down through marble for 460ft. at Plymouth, at a daily average speed of 5ft. The exhibitors show photographs of a 13in. boring at Spalding, and of other water works constructed by them. Both these firms also exhibit turnstiles.

Artesian well plant is also exhibited by Messrs. A. Williams and Co., of Great Eastern-street, who show steel tube shear-legs and other fittings for artesian borings, as well as appliances for driving tube wells when it is expected to meet water at shallow depths. Steel socketed well casing, with the points set in so as to be flush on the outside, a Curtiss single and double-action pump, and gun-metal deep well pump valves, also form part of this exhibit. A drawing of a well bored by this firm at Messrs. Salter's Brewery, Caledonian-road, in which the pump is 215ft. below the surface, is interesting as showing the various strata through which the boring passed. Messrs. Williams also exhibit the Halliday windmill, which has not undergone any modification since it was described in The Engineer.

At the next stand to Messrs. Williams may be seen an ingenious little machine for corking in vacuo, which certainly seems to possess several advantages over the ordinary corking machines. It is the invention of Mr. Bathgate, and is exhibited by the Vacuum Corking Machine Company, of Edinburgh. By the ordinary method of corking, the air in the neck of the bottle is compressed by the insertion of the cork, necessarily causing great internal pressure. In this system, the air is extracted just before the cork is driven in; this renders corking easier, and greatly diminishes the risk of breakage. Besides this, the vacuum between the cork and the contents of the bottle serves to draw the air out of the latter, and thus to check any tendency to fermentation, and prevent the growth of mould on the surface. The bottle, as in other machines of this description, is placed on a stand, which can be raised by a foot lever, bringing the neck of the bottle against the india-rubber washer contained in a cap. A tube connects this cap with the middle of the barrel of a small vacuum pump, which is on the pedestal of the stand. A hand-lever turns an irregularly toothed wheel, gearing into two racks, of which one works the piston-rod and the other the corking rod. On pulling the lever the corking rod first descends and forces the cork into the upper end of the cork tube, thus rendering the joint air-tight. This rod then stops, and the outer one commences to raise the piston, and create a vacuum in the cylinder. When the piston has travelled more than half way the end of the tube connecting the vacuum cylinder with the cap, and consequently with the neck of the bottle, is uncovered. The air in the neck rushes through it into the cylinder, and whilst the piston is travelling the rest of its course the corking rod continues to descend and drives the cork home. A disc on the hand-lever serves to set the machine for any size of cork, so that, whatever its length may be, the top is always just above the neck of the bottle.

Messrs. Buxton and Thornley, of Burton-on-Trent, are exhibiting their automatic variable cut-off gear for a horizontal engine. The engine is a 15-horse power nominal, with single cylinder, 12½in. diameter and 24in. stroke. The expansion excentric-rod works a lever with a straight slot in it. The fulcrum on which this lever turns is connected with the governor, and this, by raising or lowering the fulcrum, can shorten or lengthen the stroke. This firm also exhibit a malt mill, fitted with a magnetic separator for removing iron, and with a rotary screen for dust, stones, &c., and a set of steam pumps from 4in. by 2in. up to 12in. by 8in.

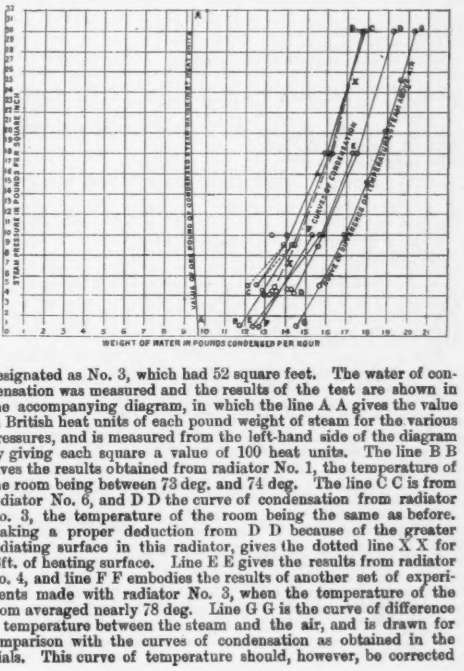
Brewers are said to be ultra-conservative, but in some respects they have taken kindly to new appliances, as this Exhibition and its predecessors show. One apparatus, which, though by no means new, has only come of late years into general use, is "Steel's mashing machine." A number of these are exhibited by different firms, all similar in general design. The one at Messrs. Buxton and Thornley's stand is entirely of copper, 18in. diameter, 60in. long. The malt, on leaving the grinding mill, is fed into a hopper at the top of the machine, whilst hot water enters by a pipe at the side. Gun-metal rakes are turned, either by hand or steam power, from a shaft which passes up the middle of the machine; and these serve both to mash the malt and to propel it forward. Brewers do not agree as to the speed at which these rakes should revolve. Some prefer a velocity of 300 to 400 revolutions per minute, whilst others think a rate of about 150 sufficient. The mash, on leaving the Steel's machine, goes straight to the mash tun, and the saving of time by this preliminary mixing is considerable. They also show a mash tun 14ft. diameter, 5ft. 9in. deep, with gun-metal false bottom and ten rows of cast iron revolving rakes. The right material for the teeth of mash tun rakes does not seem to be definitely decided. In this machine they are cast with the rake, in others they are of wrought iron. Many makers prefer gun-metal; in fact, some go so far as to make the whole mash tun of gun-metal and copper. Wood, which was formerly the usual material for these teeth, has apparently been quite abandoned, as it is not used on any which are shown at this Exhibition.

Another change of late years is in the method of making the perforations of the false bottoms. Formerly circular holes were drilled in these, but now long narrow slots, cut with saws, are generally used. Iron and gun-metal plates with these perforations are shown by several exhibitors, amongst others by Messrs. Llewellins and James, of Bristol. This firm also show another method of making perforated plates. Cast iron plates are drilled conically on each side at distances about 2in. apart, and into these apertures, copper discs, which have each been pierced with nine holes $\frac{1}{32}$ of an inch in diameter, are inserted and riveted over. By this means the advantage of a strong and rigid plate can be combined with that of having a large number of fine perforations. There are several other firms who have interesting exhibits of new machinery or appliances, but a description of them must be postponed till next week.

## CONDENSATION IN CAST IRON RADIATORS.

In the July "Proceedings" of the American Society of Civil Engineers there is an interesting paper on "Tests of Condensation of Cast Iron Radiators," by William J. Baldwin. In the course of his professional work Mr. Baldwin has occasion to test a number of good cast iron radiators to determine the amount of condensation occurring in them during ordinary conditions. These radiators were tested after the following manner:—Four radiators were placed in the same room and each enclosed in a frame covered with muslin but open at the top and bottom. The muslin was in all cases 6in. from the sides and ends of the radiators and was about 6in. from the floor, so as to permit an uninterrupted flow of air to the radiators, while preventing the radiators from transmitting heat to each other. Steam at 90 lb. pressure was employed and led through a reducing valve which was regulated to various pressures during the test. Precautions were taken to insure the steam being dry when it entered the radiators.

Each radiator had 48 square feet of surface except the one designated as No. 3, which had 52 square feet. The water of condensation was measured and the results of the test are shown in the accompanying diagram, in which the line A A gives the value in British heat units of each pound weight of steam for the various pressures, and is measured from the left-hand side of the diagram by giving each square a value of 100 heat units. The line B B gives the results obtained from radiator No. 1, the temperature of the room being between 73 deg. and 74 deg. The line C C is from radiator No. 6, and D D the curve of condensation from radiator No. 3, the temperature of the room being the same as before. Making a proper deduction from D D because of the greater radiating surface in this radiator, gives the dotted line X X for 48ft. of heating surface. Line E E gives the results from radiator No. 4, and line F F embodies the results of another set of experiments made with radiator No. 3, when the temperature of the room averaged nearly 78 deg. Line G G is the curve of difference of temperature between the steam and the air, and is drawn for comparison with the curves of condensation as obtained in the trials. This curve of temperature should, however, be corrected



according to curve A A before comparison is made. Several of the small circles on the diagram which do not coincide with any curve, indicate data that were obtained from the same radiators under different conditions of humidity and temperature.—*Railway Engineering and Mechanics.*

## STRAINS AND DEFLECTIONS IN SOLID BRIDGE FLOORS.*

By Mr. Henry Goldmark.

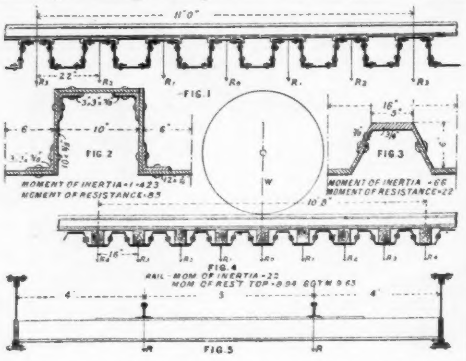
The present tendency towards heavier railroad bridges should be directed into proper channels, so that the extra weight of material may do the most good.

The best way to accomplish this result is to study present and past work in the field as well as the office; and especially to analyse such "bridge failures" and "accidents" as may occur, so as to avoid constructions that have proved to be weak.

Bridges should be safe even under untoward conditions, when trains are in bad order or derailed, and every effort should be made to accomplish this result. For this reason the use of plate and strong lattice girders should be encouraged, and an increase in the clearance between trusses is also advisable. But the best field for improvement can be found in the floor system.

Our present open floors, with stringers and floor beams, are likely to cause a disaster whenever a derailed truck reaches them. Guard rails, &c., are mere makeshifts as long as this form of construction remains in use. Solid floors, with or even without ballast, present great advantages in this as well as other respects. They give a continuous floor surface, take up little "depth," form an excellent lateral bracing, and are not unduly expensive. They should be far more generally employed than they are.

Of several forms in use in the United States two types are shown in the drawings presented herewith. Fig. 4 is the floor used by the Ill. Central Railroad in its street crossings in Hyde Park, while Figs. 1 and 2 give the plan now under construction for the Lake Shore and Rock Island companies on their elevated tracks. In both cases, the troughs act as cross-beams, and the rails as longitudinal beams in distributing weight.



If we know what proportion of the wheel load is carried by each trough, we can calculate the strains and deflections by the usual methods for beams. Hence this distribution must first be found. Though involving the elastic theory, the method of calculation used is logically correct, and should give true results.

*Method of calculation.*—If W = a wheel load over a trough—Fig. 4—then W will be distributed by a certain number of troughs, so that

$$W = R_o + 2 R_1 + 2 R_2 + 2 R_3 + 2 R_4.$$

By the principle of least work, the distribution of the loading will be such that the work of bending the troughs and the rails will be a minimum.

By a general formula dating back to Euler's time, the work of

$$\text{bending any beam} = \frac{1}{2 E I}\int M^2 d x \ldots \ldots \ldots \ldots \ldots \ldots \quad (A).$$

Where E = modulus of elasticity.
Where I = moment of inertia.
And M = moment of external forces at any point.

Applying this formula to our case—Fig. 4.

Work of bending one trough under two loads R

$$= \frac{1}{E I}\int_0^{48} R^2 x^2 dx + \frac{1}{2 E I}\int_{48}^{108} 48^2 R^2 dx$$

Which by integration and reduction

$$= 1606 \frac{R^2}{E}$$

Hence if $U_T$ = work of bending all the troughs

$$U_T = \frac{1606}{E} (R_0^2 + 2 R_1^2 + 2 R_2^2 + 2 R_3^2 + 2 R_4^2)$$

Or, by substitution,

$$U_T = \frac{1}{E} (1606 W^2 + 9636 R_1^2 + 9636 R_2^2 + 9636 R_3^2 + 9636 R_4^2 + 12{,}848 R_1 R_2 + 12{,}848 R_1 R_3 + 12{,}848 R_1 R_4 + 12{,}848 R_2 R_3 + 12{,}848 R_2 R_4 + 12{,}818 R_3 R_4 - 6124 W R_1 - 6424 W R_2 - 6424 W R_3 - 6424 W R_4).$$

Again from formula (A):—

If $U_R$ = work of bending the two rails,

$$U_R = \frac{2}{E I} \left(\int_o^l M_1{}^2 d x + \int_o^l M_2{}^2 d x + \int_o^l M_3{}^2 d x + \int_o^l M_4{}^2 d x.\right)$$

Where $M_1$, $M_2$, $M_3$, and $M_4$ are bending moments in the different panels of the rail.

By reduction this gives:—

$$U_R = \frac{1}{E} (3972 R_4^2 + 1676 R_3^2 + 497 R_2^2 + 62 R_1^2 + 1738 R_2 R_3 + 497 R_1 R_3 + 310 R_1 R_2 + 5027 R_3 R_4 + 2483 R_2 R_4 + 683 R_1 R_4).$$

Hence if $U = U_T + U_R$ = total work done,

We can write:—

$$U = \frac{1}{E} (1606 W^2 + 13{,}608 R_4^2 + 11{,}312 R_3^2 + 10{,}133 R_2^2 + 9698 R_1^2 + 13{,}158 R_1 R_2 + 13{,}345 R_1 R_3 + 13{,}530 R_1 R_4 + 14{,}586 R_2 R_3 + 15{,}331 R_2 R_4 + 17{,}875 R_3 R_4 - 6424 W R_1 - 6424 W R_2 - 6424 W R_3 - 6424 W R_4).$$

This is a function of $R_4$ $R_3$ $R_2$ and $R_1$, and will be a minimum when all the partial derivatives are equal to zero.

Differentiating we have:

$$\frac{d U}{d R_4} = \frac{1}{E}\left(27{,}216 R_4 + 17{,}875 R_3 + 15{,}331 R_2 + 13{,}531 R_1 - 6424 W\right)$$

$$\frac{d U}{d R_3} = \frac{1}{E}\left(17{,}875 R_4 + 22{,}624 R_3 + 14{,}586 R_2 + 13{,}345 R_1 - 6424 W\right)$$

$$\frac{d U}{d R_2} = \frac{1}{E}\left(15{,}331 R_4 + 14{,}586 R_3 + 20{,}265 R_2 + 13{,}158 R_1 - 6424 W\right)$$

$$\frac{d U}{d R_1} = \frac{1}{E}\left(13{,}531 R_4 + 13{,}345 R_3 + 13{,}158 R_2 + 19{,}396 R_1 - 6424 W\right)$$

Equating these to zero and reducing we have:

$$424 R_4 + 279 R_3 + 239 R_2 + 210 R_1 = 100 W.$$
$$279 R_4 + 352 R_3 + 227 R_2 + 208 R_1 = 100 W.$$
$$239 R_4 + 227 R_3 + 316 R_2 + 205 R_1 = 100 W.$$
$$210 R_4 + 208 R_3 + 205 R_2 + 302 R_1 = 100 W.$$

These equations may be readily solved and give

$$R_0 = \cdot 192 W.$$
$$R_1 = \cdot 173 W.$$
$$R_2 = \cdot 120 W.$$
$$R_3 = \cdot 080 W.$$
$$R_4 = \cdot 031 W.$$

Solving our problem by the same method we get for the second type (Figs. 1 and 2):—

$$R_0 = \cdot 39 W.$$
$$R_1 = \cdot 26 W.$$
$$R_2 = \cdot 09 W.$$
$$R_3 = - \cdot 045 W.$$

Having thus obtained the greatest load any one trough carries, the maximum fibre strain and deflection can be readily computed for any train loading.

*Results.*—We can now easily compare the relative advantages of our two floors. The shallow floor distributes its loading very widely, reducing the strains, and thus conducing to economy. It is, however, less stiff under trains, and may become loose in rivet connections from excessive deflections. Still, its elasticity is an advantage as a cushion, and it gives excellent results in practice. The deeper floor concentrates its loading, making the structure heavier but stiffer. Both floors are strengthened by an increase in the stiffness of the rail, causing greater distribution of the load. Both designs are well within ordinary limits of strain, the deeper one having the smaller stresses. For very shallow floors and heavy loads it will not cost much more than the usual floor beam and stringer construction with the same unit strains.

## THE SCIENTIFIC APPLICATIONS OF PHOTOGRAPHY.*

It is not so very long since photography occupied a very subordinate position in the world alike of science and of art. Scientific men looked on photography as a mere art, artists regarded it as a mere science. About twenty years ago, when I suggested that some improvement in a photographic process—I forget now which—ought to be brought before the Physical Section of the British Association, I was told that there was nothing scientific about photography, that it was a mere empirical pursuit, unworthy the attention of serious students of science.

And to a large extent the reproach was well deserved. Though the list of the earliest workers in photography contains many illustrious names, yet it is true that a large proportion of the most important contributions to photographic knowledge were not made by scientific workers, or by men who worked in scientific methods. They were obtained by practical men, seeking for results, often indeed seeking for them successfully by methods which could not have commended themselves to men better equipped with scientific knowledge. Of course this was the consequence of the fact that photographic science was early associated with photographic practice, and the same remark holds good of other sciences, electricity for instance, in which theory and application to practical use advance with equal steps; but I think it applies more to photography than to any other.

At the present time we have indeed reached a very different condition of things. All the most striking of the recent advances in the science are the result of elaborate scientific research. The most recent improvements in lenses were the fruit of long and laborious investigation into the optical properties and the chemical nature of certain sorts of glass. The increased speed of modern plates, and their improved power of rendering colour values more truly, have only been obtained by minute knowledge of the condition of the problem to be solved, and by careful application of the most recent results of chemical and physical research. If the old photographic crux—the reproduction of colour—has been solved; or, at all events, if a possible method has been indicated for its solution, it was not by haphazard experiment, but by careful adjustment of means to secure an anticipated result. Now-a-days we can only hope for improvement by utilising the advance of scientific knowledge.

But if the present position of photography is due to progress in the kindred sciences, how amply has she repaid the debt. There is not a single branch of science in which photography is not largely used. There are many whose progress is now absolutely dependent on the power of the camera to observe more accurately, more independently, more minutely, more rapidly, more permanently than the human eye. If, as appears to be the case, we have reached the limits of human vision, aided by the most delicate instruments that can be constructed, it is difficult to imagine what limits need be set to photographic vision, can we but construct instruments of accuracy sufficient to allow its full powers to be utilised.

The advantages of the "retina which never forgets," and, it might be added, which never tires, which accumulates weak impressions and stores them up till they become one strong one, were long since recognised by De la Rue, and I suppose it will not be very long before, for astronomical purposes, eye observations are entirely superseded by photographic. The photographic camera is now an indispensable adjunct to every large telescope, if indeed it would not be equally correct to say that the telescope is an adjunct to the camera, since the astronomical telescope tends more and more to assimilate to the form adopted long since by Mr. Rutherford, in which the visual rays are of but slight importance, and the chief attention is given to the accurate utilisation of the more chemically active rays at the violet end of the spectrum.

When we are told that a photographic plate has recorded 10,000 stars in an area not containing a single visible star, one may be excused an expression of wonder as to how the human mind is ever to grapple with problems of such infinite complexity, to turn to useful account observations dealing with such enormous multitudes. As an automatic recorder of scientific observation, photography seems to have been utilised in the Royal Observatory about 1847, under the superintendence of the venerable ex-president of the Society, Mr. Glaisher, who has been kind enough to furnish me with particulars of the methods originally devised by Mr. Charles Brooke, and successfully worked for many years by Mr. Glaisher and his staff.

The method was first applied to record magnetic variations, and the movements of the barometer and thermometer. In the case of the former, a ray of light reflected from a mirror carried by the magnet was focussed on the surface of a cylinder covered with sensitised paper. The cylinder was rotated by clockwork, the result being of course—in the way now commonly employed for such automatic records—to give, when the image was developed, a record of the movements of the magnet. A base line was given by an invariable spot of light, and by intermissions of this light a time record was provided. Similar results were obtained in the case of the barometer, by using a float with a small perforation through which the light passed, and with the thermometer by simply allowing the mercury itself to screen the light from the sensitive surface.

Later on, in 1865, similar means were used by Mr. Glaisher for the automatic record of earth currents, and they have, consequently, been continuously observed since that date at Greenwich.

To the best of my knowledge, but little alteration has been made in the original system, the only improvement being in the sensitive surface employed. When gelatino-bromide paper was introduced, it was tried and adopted at Greenwich, and by its means superior results were obtained.

Numerous instances will occur to many of you in which photography has been or might be applied. I will only refer to one, because it appears to me so excellent an instance of the delicacy of the method. At the last, the Oxford, meeting of the British Association, Mr. Burch showed to the newly-formed Physiological Section photographic records taken with the aid of the capillary electrometer of electric currents produced by speaking into the telephone. The letter z produced a complicated curve in which oscillations of current lasting only $\frac{1}{3000}$ sec. were visible with a lens.

The meteorologist has been enabled by its aid to study the form and nature of clouds, the shape and character of the lightning flash. The zoologist has been taught much about animal motion. The microscopist has long learnt to rely on the camera as the only accurate means of reproducing the objects of his studies. The physicist has by photographic methods investigated many phenomena in which the changes are too rapid for the human eye to follow them. By such means Lord Rayleigh and Professor Boys have obtained long series of pictures of occurrences which all took place within a fraction of a second, thus almost analysing time as the chemist analyses matter.

The uses of photography, in ethnology, geology, geography, natural history, archæology, are too obvious to need mention. They, and many other applications, may be summed up in the remark, that whenever the observer of natural phenomena requires to make an accurate record of his observations, photography supplies the means.

## THE SEWERAGE OF PORTISHEAD.

On October 19th Mr. Arnold Taylor, Deputy Chief Inspector to the Local Government Board, attended at the Assembly Hall, Portishead, to conduct an inquiry, the Portishead Local Board having applied for sanction to borrow £14,000 for works of sewerage and sewage disposal.

All the members of the Board were present. Mr. J. C. Clyde, Clerk to the Board, said there was no proper system of drainage at Portishead at the present time. The Corporation of Bristol were the largest owners of land at Portishead, and they raised no objection to the proposed scheme.

Mr. Moss Flower, of Carlton-chambers, Bristol, engineer for the scheme, read a report which he had prepared on the present condition of sewers at Portishead, and pointed out that there were many ill-constructed sewers and drains. He went in detail into the sewerage arrangements such as they existed, and said the drainage was as bad as it could be. He thought that if typhoid fever, diphtheria, or any other infectious disease broke out, there would be a very great difficulty in stamping it out. The report of Mr. Moss Flower was subsequently endorsed by the medical officer of health of the district.

The engineer having gone through the defective features of the present sewerage system, next went on to describe the character of the works proposed to be carried out. He stated that in all there would be about eight miles of pipe sewers; that the sewage from the low level would be lifted at two points automatically into the high-level gravitating sewer, and that the whole of the sewers on the low level would be made perfectly water-tight. The sewage from the high level would be taken out to sea, and would be discharged at all times on the top of ordinary high water.

The outfall would be constructed of 15in. cast iron pipes, supported on lines of elm piles, and taken out to a point below lowest neap tides. It was calculated that this outfall would suffice for a very large increase in population, as all rain and storm water would—as far as possible—be taken to water courses, or into the existing system of drains, which were to be repaired, cleansed, and extended where necessary. There would be manholes at every change in line and gradient, flush tanks at the top of all sewers, and disc valves on the outlets of nearly all the manholes. Some of the manhole covers would be blank, and the remainder would be of such form as could be quickly opened and closed at will. A large number of ornamental columns and ventilating shafts up the sides of the houses would be erected throughout the system. He said the gradients from one end to the other were excellent; the smallest gradient was a very short length of the main sewer, and here it was 1 in 250. Some of the ratepayers thought some of the existing sewers were good, that the sewage might cause a nuisance from the outfall, that the scheme was too expensive, and that some more modified scheme might be adopted; that they were afraid the work could not be done for the money, and that the payment of the rate would prove a hardship to small ratepayers, &c.

The Inspector remarked that if a bit here might be good, and a bit there good, it was improbable that the good part would work into the other system, and they were going to adopt a general system of sewerage, and no doubt it was an expensive scheme, but could they have an efficient scheme for less money? That he had not to pay salaries or increase them or reduce them, but as they had to raise the sewage from the low level it would necessitate expense in working; he further said it would concern cottages and castles, but they did not want an *ad captandum* appeal to the poor, the small renters would have their rates compounded for. The Inspector also remarked that they might take it from him there would be a large sum required for private house drainage in addition to the £14,000.

The Inspector, after closing the inquiry, had a private interview with the members of the Board, and pointed out the desirability of the Board enforcing the proper reconstruction of the defective house drains under close supervision, as he—the Inspector—said it was useless to put in a new system of sewers and leave the house drains as they were, or for them to be altered imperfectly. The Board at once saw the necessity of giving effect to the Inspector's suggestions. Subsequently the Inspector, in company with Mr. Moss Fowler, inspected the district, and he—the Inspector—expressed his opinion that the district, without a doubt, badly required draining, and it appeared to him that the scheme proposed well met the requirements of the case.

**Glasgow and West of Scotland Technical College Scientific Society.**—The opening meeting of the third session of the above Society was held in the Technical College Buildings, on the evening of Saturday, the 6th inst. The new President, Mr. H. Osbourne Bennie, Wh. Sc., delivered his inaugural address, the chair being occupied by Professor McLay. The title of Mr. Bennie's paper was, "Progress in Mechanical Engineering." He treated the subject in a most interesting and entertaining way, calling attention to the rapid advance made during the last twenty years, and emphasising the fact that this progress was not due to the application of recent scientific principles, but to great improvements in the methods of working, and a more exact scientific knowledge on the part of the workers. Having briefly traced the lines of progress in the departments of marine engineering and boilermaking, locomotive building, land engines, hydraulic machinery, and gas and petroleum engines, the lecturer proceeded to state that although progress was due in great measure to competition, it was also due in greater measure to the acquisition of a thorough scientific knowledge on the part of the younger members of the profession, and the careful application of the same to everyday problems. Having touched on the subject of design, dwelling particularly on the great departures which had been made when necessary from stock designs, and commonly-accepted ideas, the lecturer proceeded to deal with the decrease of cost which had characterised engineering practice of recent years, which he attributed to the greatly extended use of machine tools, and the greater cutting power and higher speed of the same. Having compared the arrangement of a modern workshop with one of thirty years ago, Mr. Bennie concluded a most useful paper by insisting on modifying and regulating the design of a machine, in order to obtain the maximum of efficiency with the minimum of cost. An interesting discussion followed, which was taken part in by Professor McLay, Professor Watkinson, and several members of the Society.

---

* Read before the Western Society of Engineers, Chicago, September 19th, 1894.

* Extracted from the address of the President—Sir Henry Trueman Wood—to the Royal Photographic Society, 9th October, 1894.

## RAILWAY MATTERS.

For want of funds the works on the construction of a section of the East Coast Railway, in India, are at a standstill, and, for the time being, the staff have been sent away to other railways and departments.

It may interest some of our readers to learn that the Glasgow and South-Western Railway Company require the services of a superintendent of the line. Proposed salary £500 per annum. Applications, marked "Superintendent," to be sent to the Secretary, St. Enoch, Glasgow, not later than Monday, the 5th proximo.

The Quebec Central Railway Company notifies the completion of the first twenty miles of the Tring and Megantic branch, which, when finished, will be sixty miles long, and will form, with the Canadian Pacific Railway—Halifax line—a shorter route by 160 miles from Quebec to St. John, New Brunswick, and Halifax, Nova Scotia.

Details of the new railway from Bristol to London, *viâ* Bath and Andover, were submitted to a private meeting of influential citizens of Bristol the other day. A committee was formed to further the project, and substantial financial support was promised. The scheme provides for a central station at Bristol, with access to the docks.

A new line from Birmingham to Coventry and on to Rugby and Northampton, joining the existing Midland Railway in the latter town, or making a direct cut to Luton, is being considered. The Midland journey from Birmingham to town would thus be shortened by at least thirty miles, and the further advantage of opening several branch lines which are now blocked would be obtained.

The Kuhlmann counter-weight cable system of operating electric railways on steep grades is to be adopted for an extension of the electric railway system of Providence, R.I., over College Hill. The *Engineering News* says the extension will have a maximum grade of 17½ per cent. and an average grade of 14 per cent. The system was illustrated and described in the above journal for June 29th, 1893.

During the twenty-seven working days of August, 301,521 double wagons of coal and coke were sent away by railway from the Ruhr district, against 285,824 wagons in the corresponding month of last year, showing an increase of 5·5 per cent.; while from the Saar district 43,543 double wagons were sent away last month, against 39.498 in August, 1893, and from Upper Silesia 118,981 against 116,333 wagons respectively.

The Agricultural Department of New South Wales has received applications for supplies of Australian hardwood sleepers for trial, namely, from the London, Brighton, and South Coast Railway for 1000 ironbark sleepers, and the Great Eastern Railway Company 2000 cut red gum. Mr. Foxlee, the engineer for existing lines—N.S.W.—states that Australian hardwood sleepers should last eighteen years, which is three times the life of the pine sleepers now in use on the English railways. The cost is, of course, higher, but beside the longer life there is a saving on the labour of re-fixing chairs and changing the sleepers.

Recent advices announce that the Brazilian Government have granted an advantageous concession for the construction of two new lines of railways. One of these starts from Faiy de Serra and terminates at Forto dos Coixas, and the other commences at the town of Itaipava in the province of Petropolis, and connects it with the flourishing district of which the chief town is Therezopolis. The construction of these lines will be of great advantage to Brazil, a country which is by no means too well provided with facilities for internal communication, considering that it stretches from 5 deg. north to 35 deg. south latitude, and occupies on a map of South America very much the same prominent position that Russia does on a map of Europe.

The liquid fuel burners of the engine Petrolia on the Great Eastern Railway burn during a month's average of over 3000 miles as follows:—Coal for lighting up, standing, &c, 11·8 lb. per mile; liquid fuel, running, 10 5 lb. per mile; total 22 3 lb. per mile. This is compared by the *Railway News* with a consumption of 34 lb. per mile of coal on similar engines on same service. On June 15th last, as we mentioned when we illustrated the fuel-burning apparatus in The Engineer, the engine Petrolia ran through from London—St. Pancras—to Scarborough and back, with a special train of saloons, dining car, &c., weighing 200 tons. The total distance is 534 miles, and consumption of fuel 11·5 lb. of coal per mile and 11·25 lb. of liquid fuel per mile, total 22 8 lb. per mile. The fire was not cleaned, and the only stoppages made were those required for water and oiling the engine.

The engineering operations in connection with the New-street London and North-Western Railway extensions in Birmingham are proceeding satisfactorily. The object is to so widen the tunnel as to allow a separate means of entrance for all Midland trains. Messrs. Holme and King, the Liverpool railway contractors, who have the work in hand, are really engaged in building a tunnel quite distinct from the one at present in use. There are at present about 120 men engaged, but as time proceeds more will probably be taken on, and operations will be continued in several places at once. The approach to the tunnel will necessitate the process of boring beneath the Great Western Railway, but this portion of the work has not yet been entered upon. With regard to the changes some distance outside the north tunnel, Mr. J. T. Firbank, the contractor, has successfully bored through the Landor-street embankment into Garrison-street. With the completion of the new arrangements, the Midland Derby line will be transferred to the Garrison-street side of the railway until just before reaching Gloucester Junction, when it will go beneath the London line and ultimately join the old route at Saltley Junction. The London and North-Western main line will at the same time be pushed over towards Landor-street until it rejoins the old line beyond Gloucester Junction, and ultimately its new course will be continued from Landor-street, and forward to the mouth of the tunnel.

In concluding a Board of Trade Report on the fatal collision which took place on the 2nd August at Newtonmore station on the Highland Railway, Major Marindin says: "In this case the 11.50 a.m. down passenger train from Perth, consisting of two engines and tenders, and sixteen—equal to seventeen—vehicles overran the down home-signal at about 3.10 p.m. and, running on to the up loop line, came into collision with the 10.40 a.m. up goods train. I must here remark, that I do not see how it can be expected that the signalling work at stations with so long loops as that at Newtonmore, where the two cabins are nearly 500 yards apart, will be carried out properly, unless there be a separate man to attend to each cabin, especially when the one man at present employed has all the duties of a porter to attend to, and I trust that the company will see the necessity of increasing their staff at this and other stations of the kind. The hours both of the station master, and of the pointsman, or porter-signalman, under the present arrangements are too long, and the employment of an additional man would enable the work to be adjusted so as to give them some relief. No time should be lost in either clearing the view from the south cabin of the down distant-signal at Newtonmore by lopping the trees which now obscure it, or providing an electrical repeater for this signal. In conclusion, I must draw attention to the long hours of duty of driver Bowie on the day before the accident, viz., from 11 a.m. to 11.45 p.m., with an interval of rest of only 1½ hours at Grantown." This labour leader sort of recommendation is very like that proposed by a recent jury, which recommended that two more men should be employed at a South London station because a child ran into the station after a ball and was killed on the line.

## NOTES AND MEMORANDA.

The rainfall during September over the Thames Valley has been deficient to the extent of nearly 1in. The actual amount falling at Oxford was 1·74in., the average for twenty-five years being 2·66in.

The following method, which may be taken for what it is worth, has been suggested for the preparation of a substitute for white lead:—Sulphate of lead is used instead of the carbonate, and is ground in oil to which from one-half to one per cent. of borax or other borate has been added.

The number of pounds of zinc consumed in the best battery, per horse-power hour, is about equal to the weight of coal required to give the same amount of energy in a steam engine; and, says *Power*, since zinc costs about fifty times as much per pound as coal, it is obvious that the primary battery is far more costly than steam in the generation of power.

The Registrar-General's returns show that Leicester has not yet been affected by the short supply of water. The deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 17 per 1000 of their aggregate population. The highest rates were those of Burnley 24·3, and Liverpool and Sunderland 22 9 and 22 6, the rates for Leicester and Plymouth being 11·9.

The following formulæ for acid-resisting cements are given in the *Bulletin Technologique*:—(1) Silicate of potash—30 deg. Baume; powdered pumice. (2) Powdered asbestos, 2; sulphate of baryta, 1; silicate of soda—50 deg. Baume—2. This resists strong sulphuric and nitric acids; for dilute acids the silicate should be 130 deg. Baume. (3) Silicate of soda, 2; sand, 1; asbestos, 1. This is the best to resist hot nitric acid.

Out of 3341 ships which passed through the Suez Canal in 1893, 92 per cent. used the electric light, thereby saving nearly eleven hours in the transit, the time occupied in passing through being with the electric light 19 hours 52 minutes, and without the light 31 hours 24 minutes. The number of British vessels included in the above total was 2405, besides thirty-nine men-of-war, and only nine casualties were registered at the British Vice-Consulate at Suez of vessels having grounded or collided.

An alloy having the appearance of silver, receiving and retaining a high polish, and which can be rolled into sheets or drawn into wire, can be chiefly obtained by the following composition:—Mixture number one is first prepared by melting 78 lb. of copper and adding first 20 lb. of nickel and afterwards 12 lb. of spelter, 1 lb. of antimony, and 1 lb. tin. Sixty-four pounds of the mixture is then melted, and 32 lb. of spelter, 2 lb. of tin, and 8 lb. of lead are added, thus forming the alloy.

In their report on the water supplied from the river Thames to London during September, Professors Crookes and Dewar say:—In spite of unfavourable conditions, usually prevailing during the winter months, the composition of the Metropolitan waters has been very satisfactory. The oxygen required to oxidise the remnant of organic matter left is slightly less than that required in August, and the organic carbon is a shade higher, but only by an amount equal to one part in seven millions.

In London 2516 births and 1326 deaths were registered last week. Allowing for increase of population, the births were 181, and the deaths 275, below the average numbers in the corresponding weeks of the last ten years. The annual death-rate per 1000 from all causes, which had been 15·3, 15·4, and 15·5 in the preceding three weeks, further rose last week to 15 9. During the four weeks ended on Saturday last the death-rate averaged 15 5 per 1000, being 2 2 per 1000 below the mean rate in the corresponding periods of the ten years 1884-93. In greater London 3372 births and 1670 deaths were registered, corresponding to annual rates of 29·6 and 14·6 per 1000 of the estimated population.

At a recent meeting of the Paris Academy of Sciences, a paper was read on the "Influence of Low Temperatures on the Laws of Crystallisation," by M. Raoul Pictet. The author shows the essential difference in the manner in which the crystallising body loses heat at the moment of solidification in the two cases where the substance is (1) adiathermanous and (2) diathermanous. All substances become diathermanous below −70 deg., and hence the true temperature of crystallisation is only obtained when the surrounding medium is maintained at a temperature very slightly below the solidifying point. Hence an explanation of the anomalies occurring in determinations of the crystallisation point of such substances as chloroform.

In a recent number of the *Comptes Rendus* is a paper on the automatic transmitter of steering directions, by Lieut. H. Bersier. The alternating current from a Ruhmkorff's coil passes from the pivot of a compass through the aluminium pointer, and leaps from the extremity of this needle to one of six vertical plates placed at intervals round the inside of the compass box. This alternating current has no effect on the magnet, but serves to work six corresponding relays, and hence to cause the illumination of corresponding signal lamps placed in various parts of a vessel, and to set in motion the steering apparatus. The least deviation from the set course is automatically and immediately corrected in this way. The course is altered by simply rotating the drum carrying the plates.

Professor Carpenter, of the Sibley College, U.S., has found that in testing for the moisture in steam by the calorimeter method, erroneous results will be obtained if the calorimeter supply is drawn from a horizontal pipe. Experiments made at Cornell showed that when flowing in a horizontal pipe, the steam at the bottom of the pipe contains much more water than that at the top. He states in a letter to the *Engineering Record* that when the moisture exceeds 1 per cent. it collects in the form of drops on the sides of the pipe, and when more than 2 per cent. is present it flows along the bottom of the pipe in a separate stream, the steam being clear and transparent, but if more than that amount of moisture is present the steam became hazy and foggy. The best place from which to draw off steam for a calorimeter determination is from a vertical pipe.

The tides of Hoihow are, according to Mr. Consul Parker, of Kiungchow, as hopeless a puzzle as ever. Though the customs authorities have now four years' records, there is absolutely no rule to be deduced therefrom. The tides outside the spit are regular enough, but those inside elude the wit of man to account for, and the level of the water outside is positively said to be often several feet above that inside. There is a tidal creek near the Consul's house, over which he can rarely walk during the day in summer, but he had walked over it every day but two at 6 p.m. during the past two months—close of last year and beginning of this—a fact which of itself renders the inner tide question inexplicable. Perhaps, says the *Indian Engineer*, the best explanation given is that of a Chinese naval commander, who says that, owing to the conformation of the spit, it is impossible for the water to flow into the mouth of the creek when the north-east wind blows and the tide is rising. That would appear to explain why, during the day, the winter tides are almost invariably low inside the spit, whilst during the night, when the wind usually drops, they have an average height. Perhaps also the blowing of the wind from the south-west direction explains why, during the typhoons of the end of September and beginning of October, Hoihow was completely under water, and the tides were 4ft. above the highest ordinary mark; but the Consul is not able to say from what direction the wind was actually blowing when the floods took place—it appeared to blow from all quarters.

## MISCELLANEA.

A complete report on the Gohna Lake is to be prepared at once by order of the Government of India.

The first meeting of the Cleveland Institution of Engineers for the session 1894-5 is to be held on the 12th prox.

The first meeting of the Institution of Civil Engineers takes place on Tuesday, the 13th prox., in the theatre of the Institution as hitherto.

The London Electric Supply Corporation, Limited, announce that the offices of the Corporation have been removed to 25a, Cockspur-street, S.W.

The Franklin Institute of Philadelphia has awarded the John Scott Legacy and medal to Mr. Ralph Hart Tweddell, M. Inst. C.E., in recognition of his inventions in connection with the system of hydraulic machine tools with which his name is is associated.

The lectures at the Morley Memorial College, Waterloo Bridge-road, which are being given at a nominal charge, began on the 5th inst., including a course of ten familiar lectures, by Professor Pritchard, on "The Care of Horses." The remaining lectures will be given on Friday evenings.

A new American rifle will soon be distributed to the United States troops and militia. It carries a small bullet, covered with a nickel-plated steel jacket, and designed either to kill instantly, or to wound without causing great suffering from blood-poisoning and other complications. The theory is decidedly humane.

At the Worcester electric light installation the day supply of current is maintained by water power, a feature which makes the station unique. Great economy will be doubtless insured thereby, as steam need only be kept up during the dark hours. A fall of 12ft. is obtained from the waters of the Teme, the turbines being 300-horse power, so arranged that part or the whole of the plant can be utilised at pleasure.

It is proposed to engage three survey parties during the coming season in determining the difference of longitude by telegraph between Karachi and Greenwich. The work will consist in the telegraphic measurement of certain arcs of longitude taken *viâ* Teheran, Odessa, and Lowestoft. The operations will probably extend over at least a year, and the subsequent calculations are not expected to be completed until the end of March, 1896.

The American Committee of Naval Construction has recommended for adoption a submarine boat according to the designs of Mr. J. P. Holland. This boat is of the usual cigar shape, 90ft. long and 10ft. 10in. greatest diameter. She is capable of descending to a depth of 70ft., and when submerged her storage batteries will drive her motor at a rate giving eight knots for a period of sixteen hours, her surface speed being 16 knots. Submersion is secured by the admission of water.

The efforts often made to induce the United States Government to devote the Naval Observatory at Washington exclusively to scientific work has at last resulted in an order from Secretary Herbert to Professor William Harkness placing him as astronomical director in charge and responsible for the publication of all work purely astronomical performed at the Naval Observatory. Professor Harkness will have power to call into counsel all the talent and experience possessed by his subordinates.

Electricity has been applied to the spinning of rope and cordage by Mr. John Good, of Brooklyn, well known as having revolutionised the manufacture of rope in the United States. Until Mr. Good took out his first patent in 1869 rope was made in the ropewalks, much after a fashion that had prevailed for centuries before. Since that time he has taken out about fifty patents for rope-making machines. Mr. Good was born in Ireland in 1844, and was brought to the United States by his widowed mother in 1851. He was early thrown upon his own resources; began to invent and rented, but did not sell, his machines.

Changes in the internal arrangements of H.M. first-class battleship Royal Sovereign are under consideration at Portsmouth. It has been suggested that the bulkheads on the belt deck should be carried up water-tight to the main deck, and that light water-tight doors should be fitted to the doorways in the armoured screens. It has also been recommended that the uptake near the small-arm magazine should be made to enter the steering compartment and form an uptake and escape from it. In addition to these proposed alterations, it is urged that something should be done to improve the ventilation of the store-room passage and the electric workshop.

Mr. J. Bowen, A.M.I.C.E., Borough Surveyor of High Wycombe, Bucks, has been recommended by a committee of the Reading Town Council for the appointment of Borough Engineer. The other candidates selected and interviewed by the Council—out of a total number of 111 applicants—were Mr. Thomas Reader Smith, A.M.I.C.E., of Kettering; Mr. Campbell, A.M.I.C.E., of Stratford-on-Avon; Mr. Witts, of Leeds; Mr. F. W. Howard, of Reading; and Mr. W. Jane, of Reading. Mr. Jane acted as Borough Engineer during the period of about three months, since the appointment of the late Borough Engineer, Mr. Collins, A.M.I.C.E., to the City Engineership of Norwich.

For the accommodation of the transatlantic cattle trade of the Mersey, the views of the steamship owners in favour of the extension of the existing lairages at Woodside, Cheshire, have been finally adopted as the most feasible way out of the difficulty. Tidal difficulties have caused the rejection of the Hornby Dock scheme, which, if carried out, would have involved the partial removal of the cattle trade from the Cheshire to the Liverpool side of the Mersey. Even the proposed extension scheme at Woodside, Cheshire, will interfere with the working of the Morpeth Dock, Birkenhead, where are located two or three lines of steamers, which have permanent berths there.

Eight of the Torquay Corporation workmen went into the main sewer, late on Friday night, at Meadfoot, to execute some repairs. At about two o'clock on Saturday morning a thunderstorm came on, and within a few minutes the water in the sewer rose about 4ft. The men were overtaken by the sudden flood, and one John Callicott, aged sixty, was carried away and drowned. The other men held on to the chains at the side of the sewer, and remained thus breast high in water until ten o'clock on Saturday, when they were drawn up in a critical condition by a rescue party organised by Mr. H. A. Garrett, the borough surveyor. It is reported that the leader of the rescue party, William Raymond, acted most courageously, going down the sewer to a depth of 220ft. and making fast the helpless men to a rope, by which they were hauled up.

The reservoirs for the water supply of Leicester present an extraordinary appearance, the water having receded a hundred yards from the bottom of the overflow weir. The post with the feet and inches painted on it to measure the depth of water is also left high and dry, and the water is now 22ft. under the overflow weir. The frost has, however, killed the small vegetable growth which prevented the water being filtered, and thus has enabled the water to be run lower than calculated. Great efforts are still being made in securing further auxiliary supplies, and the water committee hope ultimately to have auxiliary supplies of nearly two million gallons of water per day. Melton Mowbray and Ashby-de-la-Zouch are now only supplied with water eleven hours per day. Very little rain has fallen, and day by day the water in the reservoirs falls lower and lower.

## ROLLED WELDLESS CHAINS, KLATTE'S PROCESS.

The problem how to produce weldless chains is one which has taxed the ingenuity of inventors for years. The credit of having set about the solution of this problem in a practical manner belongs to Monsieur Oury, of the Cherbourg Arsenal, whose first patent dates from the year 1881. The process devised by Oury consists in the conversion of cruciform bars into weldless chains by means of boring, punching, and forging in dies, both in a cold or heated state, according to circumstances. Later, in place of punching, pressing and forging were chiefly resorted to.

In the Paris International Exhibition of 1889, samples of Oury's chains, manufactured at the French iron works of La Massardière—Department Loire—were exhibited. The first published description of these appeared in the *Eisenzeitung* of December 4th, 1890; further articles on the subject appeared in *Engineering*, of May 1st, 1891; *Stahl und Eisen*, 1891, No. 8, and 1893, No. 7; *Strasburger Anzeiger für Berg-, Hütten-, und Maschinenindustrie*, of December 1893; and some other journals.

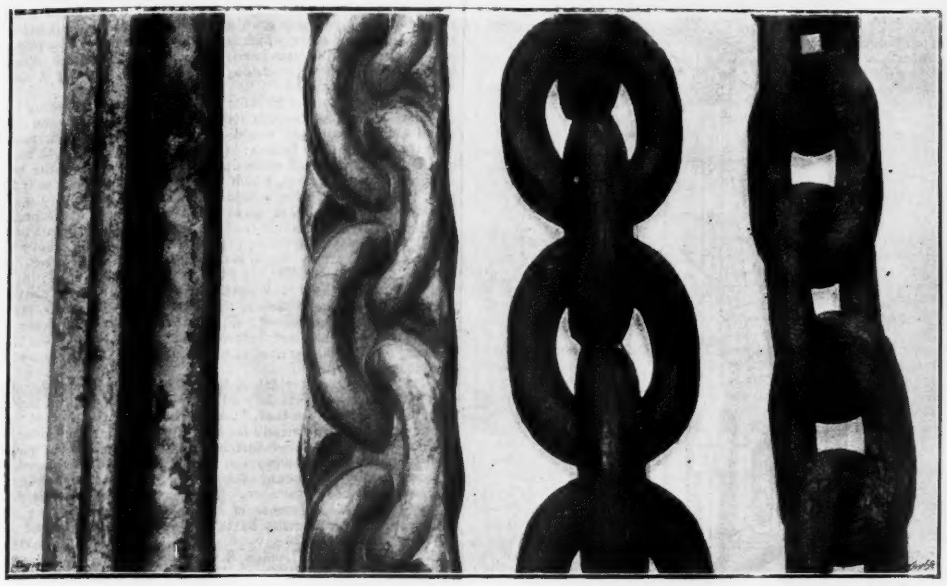

Fig. 1—THE DEVELOPMENT OF THE CHAIN FROM THE BAR

A process similar to that of Oury was patented in 1889 by Hippolyte Rougier, of Birmingham, for the production of stud link chains, which Oury had omitted to include in his patents. The manufacture of Rougier's chains was taken up by the Patent Weldless Chain and Cable Company, of Birmingham. Both Oury's and Rougier's processes involve a long series of operations, during which the metal is several times reheated with intermediate manipulations while cold. Mr. O. Klatte, the manager of the Walzwerk Germania, at Neuweid-on-the-Rhine, has recently successfully worked out a system of manufacturing weldless chains in which all the tedious operations of repeated heating, forging, and punching are avoided. This is effected by simply rolling the chains. As in Oury's and Rougier's processes, the original form is a cross bar. This is passed between four rolls, of which the working circumferences are bevelled, so that the lines of contact when brought close together are at right angles to each other. By means of these rolls the material is squeezed, where not required, inside and between the future links, into a thin web, and what, for convenience, may be called the chain bar is formed, having the shape illustrated at *b*, Fig. 1, in which *a* shows the original cross bar.

The arrangement of the rolls will be best understood by reference to Fig. 2, in which a bar is shown during its passage through the rolls with the top roll removed. The conversion of the cross bar into the chain bar is carried out in one heat. After leaving the rolls the chain bar is passed through a punching machine, with automatic feed, by means of which the webs are removed. This is done while the material is still slightly warm. In Fig. 12 the forms of the punches employed are shown. As rolled, the width of the chain links is somewhat greater, and the length consequently somewhat less, than is required in their finished state. In order, therefore, to give them their final shape, the chain bar, of which the links are still connected by a slight web where inaccessible to the punches, is reheated to a red heat and passed under a press, by which the links are reduced to the specified width. The same end can also be attained by the use of finishing rolls, which stretch the links to the necessary extent. In either case the links are finally separated during the operation. The velocity with which the chain bars are rolled depends of course upon the dimensions, and ranges from 10ft. to 20ft. per second.

Having given the general outlines of Mr. Klatte's process, we now come to the details, upon which, as in every similar case, the success of the invention depends. The detailed construction of one of the rolls is shown in Figs. 3 to 7. It consists of a central disc—secured as shown in Figs. 3 and 4 between two bevel wheels—to the circumference of which are dovetailed and keyed a number of sectors constituting the working portion of the roll in which the dies or matrices are formed.

By removing the key-piece *c* an opening is uncovered, through which one sector after another can be inserted and pushed into its proper position on the circumference. When all the sectors are in place, the piece *c* is again inserted, and the two keys *d* driven in; the latter secure the sectors against displacement. The sectors are in the first place rolled as bars, with the necessary cavities—or matrices—impressed in them. These bars are afterwards cut to the required lengths and fitted, while the finishing of the matrices is effected by cutters, on a machine specially designed for the purpose, of a type similar to those employed in the manufacture of small arms. It has been found that steel with a tensile strength of from 32 to 38 tons per square inch is a suitable material for the sectors. Instead of sectors a complete ring may be used, but for faciliting the renewal of worn or damaged parts sectors are very convenient. Experience has proved that the rolls do not appreciably suffer by use, as with all the trials which have been carried out with one set of rolls, no measurable wear has been observed. This is due to the large diameter of the rolls—from 3ft. 3in. to nearly 5ft.—and also to their high velocity.

If any supplementary shaping of the matrices is necessary, the rolls are supported on pedestals and the circumference heated to a red heat and annealed. Hitherto, no distortion has been found to result from this treatment. Damaged or defective sectors can easily be replaced. Instead of being fitted together in the manner already described, the sectors may be dovetailed together; there is no difficulty about this. In order to facilitate the adjustment of the four rolls relatively to each other, the device illustrated in Figs. 8 and 9 is adopted. This consists of an excentric fitting the central disc of each roll, and having its bearings in the wheel plates or webs between which the roll is secured. The excentric is turned by a spanner, and when adjusted is kept in place by means of a lever and set-screw, as clearly shown in the illustrations Figs. 2, 8, and 9. In the construction of the matrices many points have to be considered, not only with regard to the durability and strength of the projecting portions—or teeth, as they may be termed—but also as to the important part which is played by these teeth in displacing the material of the crossbar. The form of the teeth also depends on the shape of the links, whether long or short. As the corresponding matrices for each link on the four rolls come together, the process of rolling is in reality interrupted, and room must therefore be provided for the lateral displacement of the material. This is effected by means of a suitable distribution of space in the cavities of the rolls, and the inventor has, for instance, in the case of one set of rolls, provided for the "spreading" of the material during the process of rolling by giving the links a larger section at the points of contact, where they are subject to the greatest strain and wear.

As regards the general method adopted, the bloom is rolled in the usual manner into a bar of suitable section for the production of cross steel, having a length of about 50ft. This bar is reheated in a furnace of corresponding length, and then passed automatically through a series of quadruple rolls, arranged in line one behind the other, and calibrated as shown in Fig. 13, *b* and *c*. On leaving these rolls, the length of the bar will have increased to between 98ft. and 130ft., and it is transferred directly in the same heat to the chain-rolls, in which it is finally stretched to from 164ft. to 197ft. When longer chains are required, special wire chain links are provided for connecting several rolled lengths. The construction of such a wire link is illustrated in Fig. 14. Each of these links has a strength very much in excess of that of the normal rolled links, and is protected by a mantle or sheath of sheet steel.

Fig. 15 is a working drawing of the general arrangement of the rolls, while a perspective view of the latter is shown in Fig. 16. The cost of production by Mr. Klatte's process compares favourably with that of the old method of chain-making, and advantages over the latter in other respects are claimed. The accompanying table gives the results of official tests, carried out at the Royal Experimental Institute at Berlin, with "Klatte" chains of different kinds of steel, and also with an ordinary welded chain. The machinery as described is being introduced into this country by Mr. G. R. Bodmer, of 30, Walbrook, London.

## NATIONAL FREE LABOUR CONGRESS, LONDON, 1894.

The following agenda of business to be considered at the forthcoming second annual Congress of the National Free Labour Association, to be held at the Forester's Hall, Clerkenwell-road, London, E.C., the week commencing Monday, October 29th, 1894, has just been issued:—(1) Reception of provincial delegates; (2) examination of credentials; (3) election of a chairman of Congress; (4) call on general secretary for yearly report of Executive Council, and correspondence by the secretary; (5) chairman's opening address.

The following resolutions will be submitted to the Congress:—

*First resolution.*—That in the opinion of this Congress the senseless and abortive strikes which have occurred in many branches of industry throughout the country have had a most disastrous effect upon the living standard of the wage-earning classes, and are mainly the cause of the present stagnation of trade and consequent want of employment.

*Second resolution.*—That the Congress declares the time has arrived when the law relating to picketing should be so amended that some clauses may be included which shall abolish picketing, and that in lieu thereof, it may be lawful, when a dispute arises, for both sides to put outside the works affected a printed notice giving their different versions of the points in dispute. *Amendment:* That while recognising the legal right of workmen to picket during strikes for the *bonâ fide* purposes of giving and receiving information, picketing in such numbers as must inevitably terrorise those who may be willing to work shall be prohibited.

*Third resolution.*—That this meeting, representing the vast majority of the working classes in the United Kingdom, enters a most emphatic protest against the re-introduction of an Employers' Liability Bill containing a clause forbidding "contracting out," and calls upon all workmen by their individual influence to support the House of Lords in throwing out a measure which deprives working men of their undoubted right to make better terms as to insurance against accident than the law now permits them to do, and one also which forces a workman to the expense of a doubtful and expensive lawsuit in order to obtain a smaller sum than would be awarded to him free of expense by his mutual insurance society.

*Fourth resolution.*—That this Congress of the National Free Labour Association rejoices to learn that the free labour principles are making steady and certain progress amongst the industrial classes of the country, who recognise the necessity for the permanent maintenance of a free labour party so as to resist the ever-encroaching tyranny and dictation of the Socialistic trade unions.

*Fifth resolution.*—That this Congress, taking into consideration the aggressive tactics of the various unions connected with the printing and allied trades, recommend the executive to at once open a registration bureau in the City for the registration of non-union printers' workmen.

*Sixth resolution.*—That in the opinion of this Congress the time has arrived when it is absolutely necessary that some restriction should be placed upon the immigration of pauper aliens to this country, and is pleased to note that the Trade Union Congress has at last accepted the views that this Association has so long advocated in the matter. And further, that this Congress earnestly hopes the Bill restricting pauper immigration, recently introduced in the House of Lords, shall be allowed to become law, and that a copy of this resolution be forwarded to the leaders of both political parties.

The chair will be taken at 6 p.m. each evening, and the Congress will sit until 10.30 p.m. Any representative attending the Congress, and being desirous of submitting any special resolution bearing upon the labour question to the consideration of the Congress, is requested to send a copy to the secretary, Mr. William Collison, National Free Labour Association, 79, Fenchurch-street, London, E.C., on or before the morning of the meeting.

**Sell's Directory.**—We have received the third and last supplement of Sell's "Directory of Telegraphic Addresses for 1894," which brings the volume up to date. Mr. Sell draws attention to the unauthorised attempts of some directory publishers by the aid of Sell's Directory to incorporate in present directories matter which has been compiled at great trouble and expense in the past by him. We trust that their attempts will only meet with the failure they deserve.

# LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### THE THEORY OF THE STEAM ENGINE.

Sir,—In my last letter I gave Mr. Cross three "nuts to crack." Your readers who take an interest in the matter will note his failure to reply justifying his statements as regards any one of these distinct and clearly defined points, and should hence know at what value to assess the value of such other parts of his communications as—to avoid entering on a wider field than was necessary to my purpose—I have elected not to deal with.

I presume I need say nothing further in substantiation of my statements of fact. Henry Cherry.

21, Festing-road, Putney, S.W.,
October 19th.

Sir,—I am glad to notice Professor Peter Alexander's letter in your pages protesting against the mistaken teaching in nearly all modern text-books on heat-mechanics, and against the unfairness of fathering these mistaken notions upon Carnot.

It cannot be too distinctly stated that Carnot's closed isothermal-adiabatic indicator diagram was invented solely for the purpose of giving a mathematical demonstration of an all-important law in thermodynamics. But to put it forward as the diagram of an engine having any special claim, either theoretical or practical, to the title "perfect," or as the diagram towards which engineers should strive to make their engine diagrams approximate, is a pure absurdity. Also to imagine that an engine giving this diagram would be in any special degree "reversible" beyond other engines is a simple delusion.

The common definition of the "absolute efficiency" of a thermodynamic engine is "the ratio of the work done to the heat supplied," the heat being supplied by conduction or radiation or electric current. This is meant to be generally and universally applicable to all heat engines; but, being general, it can hardly be correct, because under certain conditions no such supply of heat is required in order to obtain mechanical power by the heat action of the working substance. I do not allude to the evident fact that adiabatic expansion under pressure results by itself in work being done. I allude to the further fact that under tension, in order to increase the work done beyond that obtainable by adiabatic contraction, it is necessary, not to supply, but to abstract heat from the working substance. No doubt, if the "cycle" be closed, both conductive supply and abstraction of heat are necessary; but then the cycles of real working subtances never are and never can be closed. In the case of pieces in tension, it is the abstraction, not the supply, of heat that is really effective in producing extra mechanical power. Robert H. Smith.

Mason College, Birmingham,
October 20th.

Sir,—I have read Professor Alexander's letter in your last impression with very great pleasure. It is an ample endorsement of the soundness of my views. But may I not ask how it comes to pass that admissions of this kind have had to be wrenched, so to speak, from writers on thermodynamics by humble engineers like myself? Even now there is no universal admission of the truth. Take, for example, Dr. Lodge's papers on "Carnot and Modern Heat." There is nothing in these papers to show that Carnot's views and propositions have anything whatever to do with the steam engine.

The philosophers, with a great blowing of trumpets and beating of drums, told the engineers that they—the philosophers—would draw the line for them beyond which it was impossible to go in developing the heat engine. Why should it be left to me and such as I to prove that the philosophers' line had nothing to do with steam engines or heat engines of any kind recognisable as such by engineers? Does it not strike Professor Alexander that he is just a little late in the field? However, he has a chance still of doing good service. Let him demolish another text-book fetish. We are continually told that the efficiency of a heat engine is independent of the nature of the working fluid or substance. This is possibly quite true of a mathematical formula. Anything can be proved to be true by mathematics, if only certain postulates are granted; but it is not in any sense or way true of a real heat engine. No one, for example, can say that steam is as good a working fluid as Dowson gas; no one can prove that air is not from the purely economical view a better working fluid than steam—the difficulties in the way of its use being purely mechanical. If Professor Alexander will boldly use his influence, and instead of saying that all fluids and substances are equally efficient, will explain why and how it is that some fluids and substances are better than others, he will do excellent work. Errors die hard, but it must, I think, be admitted that it has not been the engineers but the physicists who have been in error. It has been once said in your pages, Sir, that Carnot did absolutely nothing in the development of heat engines, that his investigations have been entirely barren, that the deductions drawn from his utterances have been misleading. It has remained for Professor Alexander to prove the truth of these propositions by showing the reason why. Maurice Cross.

October 22nd.

### GOVERNING ELECTRIC LIGHT ENGINES.

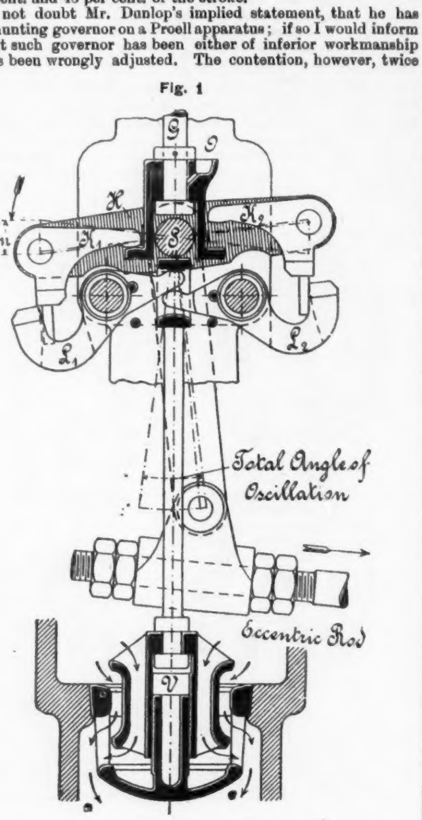
Sir,—I have refrained from entering into the correspondence about governing electric light engines, as I had no wish to appear desirous of advertising the Proell inventions, which I represent, in your correspondence columns. The unwarrantable attack which Mr. James Dunlop, in your issue of 19th inst., levels against the Proell apparatus leaves me, however, no option but to ask you to insert the following explanation and contradiction.

Mr. Dunlop would have done much better to put his signature under the first four words of his letter. He parades a fact before your readers, makes a high-sounding analysis of the same, draws sweeping and condemnatory conclusions, coupling them with some sinister insinuations about the function of the governor, and all this in delightful ignorance that the fact on which he bases his charge has been for a very long time simply non-existent. He does not know that the two valve lifters are perfectly independent of one another, as the two illustrations herewith prove. In Fig. 1 the mechanism is shown immediately before the release of the valve, the idle lifter $L_2$ has remained during the whole stroke of the active lifter $L_1$ at rest in the position shown, viz., the identical position in which it is still left in Fig. 2, where the valve is tripped off and has come to its seat. I trust Mr. Dunlop will either show how it is possible that under such circumstances the idle lifter can in any position of the governor-rod G he chooses "arrest the falling valve," or else he will apologise to your readers for having made such misleading statements.

Mr. Dunlop possibly only knows an obsolete and discarded construction of the Proell apparatus, and I think he has committed a great indiscretion by rushing into print with allegations of a serious nature against an invention about which he knows so little; if the reputation and success of the same were not happily above misrepresentations of this kind, great harm might have been done to it. Mr. Dunlop's erroneous contentions, as they stand, strike at the present construction of the Proell apparatus as well as at the earlier one. That they are totally wrong as regards the former, I have shown; as regards the latter, it is rather late in the day to point out alleged faults of the same, as no apparatus have been made to that design with my approval for years. Still, as a matter of mere historical interest, I would point out that Mr. Dunlop's calculations and conclusions are equally misleading as regards the obsolete construction. To explain this graphically would take up more space than you would grant me for such a matterof limitted interest. I think, however, that the enclosed original indicator diagrams, taken from an engine under the control of the first Proell apparatus set to work in this country ten years ago, will prove that even that comparatively primitive execution of the leading idea secured for an engine what was claimed for it, viz., automatic variable cut-off at any point of the stroke, and not as Mr. Dunlop's mistakes pretend to make out, "no control between 16 per cent. and 43 per cent. of the stroke."

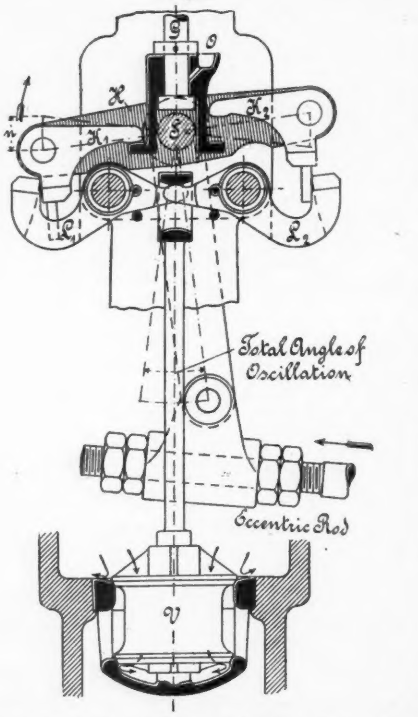
I will not doubt Mr. Dunlop's implied statement, that he has seen a hunting governor on a Proell apparatus; if so I would inform him that such governor has been either of inferior workmanship or it has been wrongly adjusted. The contention, however, twice repeated in Mr. Dunlop's letter, that such hunting is intentional, and the Proell system relies on a hunting governor to cross the interval between 16 per cent. and 43 per cent., I can only characterise as a piece of gross ignorance or culpable negligence in drawing conclusions. It is nothing short of an insult to the intelligence of thousands of users of the Proell apparatus to insinuate that the advantage they have actually derived from the same during the last ten years has been a delusion, and that they have been deceived by a worthless device; and that from a critic whose knowledge of the subject is evidently superficial.

Fig. 1



Mr. Dunlop says he does not know whether there are any Proell apparatus engines driving electric light. I can refer him to more perfectly successful installations of this kind than he would care to inspect. Factories where such engines drive sawmills with circular saws, big rifling lathes for ordnance and other heavy machinery simultaneously with the dynamos for lighting, and without the use of accumulators. And that is what Mr. Dunlop calls "regulation of any sort."

Fig. 2



Into the controversy of regulating engines driving this or that kind of dynamo I have no desire to enter. I shall, however, be glad to place Proell apparatus for a free trial at the disposal of any *bonâ fide* applicants who may be interested in the question; so far I have never yet failed in attaining the degree of regularity required by the electricians in any engine I have undertaken to convert. Hermann Kuhne.

October 24th.

### THE CONDITION OF THE THAMES BELOW KEW BRIDGE.

Sir,—In your article on the above subject in your paper of October 5th your concluding remark strikes the real keynote of the matter. You say that "it may be questioned whether shortness of memory does not account for most of the supposed changes." That is the real fact. The ebb tides have been becoming steadily lower year by year for many years past. Records are before me which show, for instance, that the ebb tides at Hammersmith were lower in 1894 than in 1893, but those in 1893 were much lower still than those of 1892. The Stoney Weir at Richmond was not brought into use until May 19th, 1894, and it has certainly had no material influence on the ebb tides.

Boating men are apt to compare the visit of one season to a particular spot, with the visit of another season, without taking notice that one was made at, say, half tide, and the other happened to be at the ebb of a spring tide. Like times of like tides have manifested a difference, but not much recently—not enough to be observable without the aid of instruments. The tidal records clearly demonstrate this.

The fact is, that from the time when the Richmond weir was first proposed, the attention of those interested in the river has been more directed to the subject than before, and it is human nature to regard—with some unconscious jealousy—the remedy which has been found for one part, as if it were the cause of mischief to another part. The trouble lower down is not a thing of yesterday, it has been growing these fifty years, and it has now attained a seriousness which calls for a remedy. Happily the remedy is ready to our hand, and as it is one which does no mischief either above or below, there is no reason why it should not be promptly applied.

It is always a work of time for the details of any new thing to be familiarised, and as there is much misconception as to the Richmond weir, perhaps you would allow me to remind your readers that its working is as follows:—(1) On all flood tides, both by day and by night, the great sluices are lifted entirely out of the water at the time of half flood, which then goes as freely up as it ever did; (2) on all ebb tides, except about ten in the month, they are put down at half ebb, so as to retain some water at Richmond; (3) the quantity so retained is about one twenty-eighth part of the whole water passing the site; (4) the sluices are never wholly shut down, the land water—which is the bulk of the whole—passes down as freely as it ever did; (5) there is no stagnant pond; (6) the weir has not caused any settlement of mud either above or below, but, on the contrary, the river at Richmond is rapidly becoming very clean indeed; (7) the traffic on the river has a new facility which it had not before, although the bulk of the traffic—being really tidal—arrives at a time when the 66ft. arches of the bridge are freely open.

Of course, the water taken by the water companies from the river is an element materially affecting it at low tide, but the weir cannot be blamed for that. On the contrary, the weir at Richmond is already the remedy for it at Richmond, and a similar weir would give similar relief further down. Now, as to the question of how much further down the next weir should be placed, this is governed by the amount of difference of level permissible in an engineering sense at the spot. If we go too far at once, we should have to make the difference of level too much to suit the many requirements which must be taken into account on sound engineering principles. Richard C. Rapier.

### DETECTION OF ARSENIC IN COPPER.

Sir,—The detection of minute quantities of arsenic in copper, a process of great importance when the metal is to be used for electrical purposes, usually necessitates the expenditure of considerable time and labour on the part of the chemist. In the current issue of the "American Journal of Science" F. A. Gooch and H. P. Moseley describe a method by means of which a proportion of arsenic as small as five ten-thousandths of 1 per cent. may be not only detected but approximately estimated. The method employed is an adaptation of Sanger's successful process of estimating traces of arsenic in wall-papers, &c., in which the liquid suspected to contain arsenic is introduced into a hydrogen generator, and the gaseous arsenuretted hydrogen thus produced passed through a heated tube, when a mirror of elemental arsenic is deposited on the walls of the tube, as in the well-known marsh test. By comparing the mirror thus obtained with standard mirrors produced under like conditions with known quantities of arsenic, it is possible to approximately estimate the amount of arsenic in any given liquid. In order to determine the arsenic in copper, the authors dissolve about one gramme of the metal in nitric acid, remove the latter by means of sulphuric acid, and separate the arsenic from the copper by distilling the solution with hydrochloric acid and potassium bromide. The liquid distillate containing the arsenic is introduced into a hydrogen generator, and a mirror obtained as explained above. The method is most properly applied to electrolytic copper, in which the quantity of arsenic may vary ·01 per cent. to ·0005 per cent. G. E. B.

Putney, October 22nd.

### TRAINS AND LOCOMOTIVES.

Sir,—Mr. Percy Caldecott's letter in your issue of 12th October certainly hits the right nail on the head when it inveighs against the Midland Railway for fitting its coaches with archaic door handles, which are not only non-automatic, but give infinite trouble to the public and railway officials by requiring a great muscular effort applied in two directions at once to manipulate them. As for their thin 26in. by 24in. metal plates which do duty for footboards on many of their coaches, it is certain that some day someone will be killed by them, and that they could not be defended before a judge and jury.

While I am writing on the few Midland shortcomings, may I mention one huge mistake they have made lately—I refer to the new dining-cars, which they own jointly with the G.S.W.R., and which for some inexplicable reason are not vestibuled to the rest of the train, so that only those who can get seats in them right through from the start can use them, unless, indeed, by the very great inconvenience of changing out and in at stations, at the risk of one's belongings left behind. In 1894 such a blunder is inexcusable.

Mr. F. Bowles, in your issue of 19th October, is quite right in thinking that East Coast rolling stock is heavy to haul; for this is notorious, and is caused by the fact that they persist, in the face of common sense and universal practice, in building six-wheeled stock, which of course by its rigidity causes much friction on the rails and at the axle-boxes. Times without number this route suffers from hot boxes; the new dining-car trains at first averaged one a day for months. One has only to travel in a bogie carriage and then in a six-wheeler, and to feel the silence and gliding motion of the former and the jerking and grinding of the other, to realise the wear and tear of a rigid coach on the rails and itself, which all spells money in wheels, axle-boxes, haulage, and rails. In a bogie carriage one can talk with comfort, as the wheels are not fastened to the frame, which conveys the noise upwards. The ideal express train is the American and Australian of coaches on six-wheeled bogies, about 70ft. to 80ft. long, and vestibuled throughout. It is cheapest and safest in the long run.

Mr. Bowles is wrong when he says the new N.E.R. 94-ton locomotives are compound; only one is—1619—and she was not in the Northallerton smash. Norman D. Macdonald.

15, Abercromby-place, Edinburgh.
October 20th.

Sir,—Your correspondent, F. Bowles, is justified in calling attention to the comparative inefficiency of certain modern locomotives, a subject which deserves from railway shareholders more attention than it receives. He is wrong, however, in supposing that one of the North-Eastern compounds was in the Northallerton collision. The train on that occasion was drawn from Newcastle by No. 1622, one of the new engines, with cylinders 19in. by 26in. At Darlington it was found that a pilot was required, and No. 905

an engine built by the late Mr. Fletcher, was attached. Judging from the performances of the Fletcher engines for nearly a quarter of a century, there can be no doubt that No. 905 could have worked the train unaided.

The day after attending the Midland Railway meeting at Derby last August, I travelled from York to Newcastle by a portion of the ten a.m. express from King's Cross. With a moderate load, in beautiful weather, the North-Eastern Company sent on that train one of their largest compound singles, and one of their very large new engines of the 1622 class, weighing together without their tenders just under 100 tons. Remembering the offhand way in which one of the Fletcher engines, in the good old days, would have dealt with such a train, one cannot help wondering what the "progress" of recent years has really cost. It is a curious thing that the most successful engines which have ever run on the North-Eastern road were built at a time when the company was without a locomotive superintendent at all.

Had Mr. Bowles been at Carlisle this evening—October 20th—he might have seen a North-Western corridor train, composed of one six-wheeler, six eight-wheelers, and two dining cars, leave for the south, drawn by Mr. Webb's Greater Britain, and a rebuilt 6ft. coupled engine, of about as simple and cheap a type as could be constructed. In this case also the pilot by itself could have worked the train without difficulty, so that it is hard to see wherein the advantage of these enormously heavy and expensive engines lies.

W. B. Thompson.

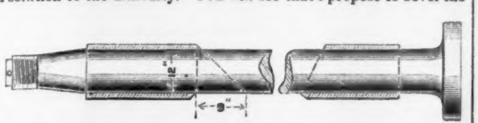
October 20th.

Sir,—I should be much interested if your correspondent in last issue, Mr. F. Bowles, would state on what railway "Mr. Macdonnel's" locomotives referred to may be found.

Cannon-street, London, E.C., Scrutator.
October 22nd.

### CORROSION OF PROPELLER SHAFTS.

Sir,—Referring to your issue of September 28th, and your remarks and illustrations on the above subject, and also the remedies proposed for the preservation of the shaft at the point where the liner ends on the shaft, I suggest that the enclosed sketch offers a solution to the difficulty. You will see that I propose to bevel the liner, in order that the circular current of water carried round by the liner may be broken up, and I venture to think that in removing one of the evident sources of corrosion, the evil will be readily and inexpensively overcome.



London, October 22nd. Consulting Engineer.

### BICYCLE MECHANICAL ENGINEERING.

Sir,—I am pleased to see your article under the above heading, pointing out the mechanical absurdity of the Boudard gear; but whilst I agree with you on this point, I think an explanation is needed of the fact that the gear in question does actually appear to drive a machine with greater ease to the rider than the ordinary direct chain gear. I believe this is due to the chain wheels of the ordinary gear being made too small to transmit the work of the rider, without excessive friction in the chain itself and in the axle bearings. With the ordinary proportions of crank and chain wheel, the rider's thrust upon the pedals is multiplied two and a-half times on the chain, and when the rider is doing his utmost, the pull thus brought on the chain and bearings is very great. In the Boudard gear a higher speed for the chain is obtained by the use of the intermediate wheel and pinion, allowing a larger driven chain wheel to be used on the hind wheel, and it would look as if the reduced friction of the chain gear under these improved conditions not only compensated for the friction of the extra wheel and pinion, which can hardly be less than 5 per cent., but left something to the good. If this should prove to be the case, we can secure the whole gain without the attendant loss by retaining the direct drive, but making the chain wheels larger, say double the present sizes, and this need not materially increase the weight, as lighter wheels and chain would suffice for the reduced strains. I am pleased to see a statement in a cycling paper, that larger chain wheels are to be the feature of next year's machines, as I have long held this to be a greatly needed change.

Whilst on the subject of bicycles, I should like to say a word as to the size of the wheels. It always seems wrong to me to have a 30in. front wheel to carry one-fifth of the rider's weight, and a 28in. wheel to carry the remaining four-fifths. I think that a larger hind wheel would justify its extra weight, particularly on heavy roads.

The diagrams illustrating your article, which I, of course, understand are only sketches, hardly serve to bring out the point I wish to make. As they stand the ordinary gear has a ratio of about 2 to 1, and the Boudard 4 to 1. Equalise the ratios by doubling the diameter of the driven wheel in the latter case, and you will see the advantage I point out.

J. G. H.

Bolton, October 22nd.

### LABOUR AND LUXURIES.

Sir,—Your correspondents "Hirn" and "W. A. S. B.," in replying to my letter, leave the facts untouched. Calmly considered their arguments simply amount to a statement that ethics and morals ought not to be ignored in political economy. On this point I have expressed no opinion whatever. Of course Mill, and indeed almost every writer on the subject, call attention to the operation of such things as natural affection, religious feeling, &c., but they do not assert that these affect the laws of the science in any way. They may affect the operation of those laws, just as mercy may free a criminal whose life is by law forfeited, but this is quite another matter. The utterances of standard authors on this point have nothing whatever to do with the facts to which I directed attention, and which none of your readers attempt to gainsay.

I may put the question in a yet stronger light than I have done yet. A is a working man who has just been paid his week's wages, two pounds. B is also a working man out of a job. B murders and robs A. He lives in A's district, and he spends the two pounds which he has stolen on food and drink at the shops at which A habitually dealt. Now, morally, B's action was the worst possible. But so far as the shopkeepers are concerned, the result is just the same as though A had spent the money; there is a change of distributor—that is all. The whole matter can be put in a nutshell by using the well-known small trader's phrase, "One man's money is as good as another's." In political economy it matters nothing how the gold has been got, or how it is expended, so long as it is expended. In the old days an Italian noble wrung gold by oppression from tortured vassals, and he expended this gold in hiring a bravo to assassinate an enemy. Ethically, nothing can be more reprehensible. Political economy takes no cognisance of a crime. The bravo's gold was just as good to those on whom he spent it as any other gold won in the most honest possible way.

Very many cases arise in which I think money is badly distributed. Thus, for example, a man may give a sovereign for a bouquet, which would be better expended on a starving widow. But that is so only because a time element is introduced. In the long run, so far as the whole community is concerned, the result would be the same whether the sovereign went to the gardener or the widow; and, if the widow died, the community would be on the whole better off, because there would be one less mouth to feed. If any of your readers can controvert the truth of my propositions let them do so; but to argue about them on sentimental, or charitable, or merciful grounds, is quite beside the case. So long as a sovereign is spent—that is to say, put in circulation—it matters not one straw on what it is spent, moral or immoral. The result to the community as a whole is the same.

If we leave political economy on one side for the moment, and consider expenditure in its ethical aspect, we may ask what is meant by the word "luxury." It is certain that what was luxury at the beginning of this century is regarded as necessary at the end of it. The facilities for production of necessaries are now so great that much more food, for example, of all kinds is available than seems to be needed. Wheat may be cited as an example. It will indeed be generally admitted that to employ more hands in this direction than are now employed would be a vain thing; but employment is still to be found in producing the superfluities of life, which are now enjoyed more or less by all but the very poorest.

If your correspondents will try to put sentiment on one side they will see that what I have stated is strictly true. Men are simply distributors of gold. They work to obtain their turn in the use of it, and then pass it on to someone else, who has it in his turn. It is open to anyone to say that A distributes money badly and that B distributes it well, but in the long run the result is the same whether the gold is in the hands for a time of such men as Mr. Peabody or the Emperor Caligula.

Well-meaning people, however, insist on mixing ethics with political economy. They spoil their political economy by the admixture of ethics, and then ruin their ethics by mixing them with political economy. This is one reason why promiscuous charity does so much harm. It is *the* reason why the administration of charity to advantage is the most difficult task conceivable.

It is perhaps a satisfaction that no one is responsible for the laws of political economy any more than we are for the laws of gravitation.

Y. X.

October 22nd.

### AN OLD TIME PUMPING ENGINE.

Sir,—The other evening, accompanied by a friend, I went over to the —— Colliery, near Bristol, to see a fine old specimen of the Newcomen atmospheric pumping engine at work. As the pit is fairly dry the engine is only worked during the night for about two nights a week. On arrival at the colliery we hunted up the engineer, who provided us with a couple of lamps and conducted us to the ancient driver. This individual, who looked fully as old as his engine, but who, in response to sympathetic inquiries, assured us that he was not so "owld as 'a looked," led the way to the engine-house door. This having been persuaded by gingerly treatment to open without falling in, we descended a flight of steps covered about 6in. deep with dust, and reached the basement. The cylinder of the engine is 6ft. internal diameter and about 10ft. stroke, the valves being worked partly by hand and partly by means of a heavy plug rod hung from the beam.

Naturally the construction is extremely primitive, and the ironwork never having experienced the luxury of a coat of paint is in a very advanced state of decomposition. Some of the smaller flanges past which the steam has been leaking for perhaps a hundred years are fully three-quarters rust. Amidst clouds of steam we stumbled up the dusty steps to the top of the cylinder and were shown a place where the cylinder side had been rusted completely through, but which had been successfully stopped up with cement! Water packing is used for the piston, a 2in. pipe delivering a constant stream of water on to the top side, which being helped by the atmosphere on the indoor stroke, leaks through as fast as it is delivered. This method of water packing is to be preferred to the other elegant method adopted in the old days, which consisted in shooting a load or two of dung on to the top of the piston. The beam is a wonderful structure, with a "horse's head" at each end, the inner end being connected to the three piston-rods by means of stout chains. Our guide related how the soundness of the cylinder bottom had been tested more than once by the snapping of these chains, the piston and rods coming down with a crash. The steam is taken from a large receiver, which is in connection with the main boilers of the colliery, the pressure, of course, being greatly reduced.

The engine, according to the driver, was put down upwards of 100 years ago. The old man had driven it himself since the days when he was a boy so small that he had to stand on a block to reach the valve handles, and his father and grandfather had driven it before him. At present there appears to be nobody but the old driver about the colliery who is sufficiently acquainted with the idiosyncrasies of the engine to be able to work it, and as there is a possibility that that patriarch will at some future date depart from this earthly life, it is supposed that from that date the engine will be allowed to rest in honourable retirement. It is even possible that it will one day grace the interior of the noble building at South Kensington which has become the last refuge of many engineering antiquities of a more recent date.

October 22nd. H. Verney.

### ROPE DRIVING.

Sir,—I do not know whether I may interest your readers by giving the following:—Messrs. Ashton Bros. and Co., of Hyde, have just started a pair of triple-expansion horizontal engines, by Goodfellow, of Hyde, 500-horse power, for driving their weaving department. The main driver is 97ft. centres, 24 1¼in. ropes. This is, so far as I know, the longest horizontal main drive in the world. The whole of the alterations and designs are and have been superintended by

J. Gillaird.

Edna-street, Hyde, October 24th.

## WATER SUPPLY.

By Professor Henry Robinson, M. Inst. C.E., F.G.S., F.S.I.*

It is proposed in this paper to refer to a few points bearing on the question of water supply that are the outcome of recent observations of chemists and bacteriologists, to whom engineers are indebted for clearing up difficulties which they have experienced in advising on this subject.

It has been contended by some that no stream should be utilised as a source of water supply if it had been subject to the slightest sewage contamination above the point of intake, and that unless the stream was absolutely free from even the suspicion of sewage pollution, it should be condemned as unfit to furnish a supply of water for dietetic purposes. It was formerly the custom to classify waters as "turbid," "slightly turbid," and "clear," and analyses of waters were made with a view to determining their purity entirely from a chemical standpoint. At the present time, however, a biological investigation is an essential part of the scrutiny that a water has to undergo. The "self-purifying" action of a stream is an important factor in effecting the destruction of pathogenic germs. If it were not for the natural purification which a river undergoes, the continuous discharge of even slight quantities of sewage or polluting matter into it would produce cumulative evils that would in time render every such stream an abomination. In writing on the subject of sewage disposal ten years ago the author stated:—"It has often been contended that organisms injurious to health derived from sewage decomposition continue to live after their discharge into a river, and are practically incapable of being destroyed. Alarmists have relied on this in support of the contention that no river water is fit for dietetic purposes. I think this view has been overstrained. Is it not a reasonable assumption that these organisms may be quite incapable of existing when favouring conditions cease? This must be the case when, after they are cast into a river with the filth they thrive on, the whole becomes largely diluted, its temperature altered, and a state of things produced very different from that which previously existed." The recent inquiry about London water led to the expression of opinion that "When pathogenic bacteria pass into the outer air or water they are in an unnatural medium in which they can only maintain their existence and power of multiplication for a limited period, during which they undergo more or less rapid attenuation or loss of virulence, and become generally weakened."

The author is the last to under-estimate the importance of preserving water supplies in the purest possible condition, but he wishes to combat the merely sentimental part of the case, which at times may lead to the imposition of grave burdens on communities in regard to water supply. In the application of the Rivers Pollution Prevention Act no efforts should be relaxed to prevent the streams from being employed as vehicles for carrying off sewage or manufacturing refuse. The standard of purity should be maintained high, and legislation should be made more compulsory to preserve the purity of the streams, both from a sanitary and æsthetic point of view.

Much information is now available in regard to the conditions under which the micro-organisms exist that are found in water, and the relation between the harmless and the harmful—or pathogenic—germs. Bacteriologists indicate that typhoid bacilli cease to have vitality in fœcal matter in fourteen days. However that may be, all agree that their capabilities of mischief and of multiplication are greatly lessened in a very few days.

Some of the chief causes of the destruction of these germs may be indicated briefly and generally. Low temperature is a factor adverse to their prolonged life, as they flourish in a higher temperature than that of river waters. Innumerable harmless bacteria which exist in rivers are found to be mortal enemies of the harmful bacteria. Light has an influence unfavourable to their existence, although the agency of light in destroying germs does not appear to be effectual at all depths. In shallow streams it is a more powerful factor in assisting their self-purifying action, than in deep sluggish rivers. Recorded experiments on cholera bacilli show that their virulence is greatly diminished by exposure to sunshine. Daylight without sun has also been proved to destroy them. The subsidence of suspended matter carries down germs which perish. Minute plants liberate oxygen under the influence of light, and assist this purifying action.

Bacteria appear to multiply more rapidly in pure water than in impure. In unboiled water they are found to multiply slightly, but in boiled water they multiply greatly. Miquel established this, and explained it as the action of a zymotic disease, by which the water that originally contained bacteria was inoculated against them, whereas a pure water was not. The same result was arrived at by the experiments of the State Board of Health of Massachusetts, and by Dr. Percy Frankland. He found that pure moorland waters—which are regarded as unobjectionable sources—were very favourable to the cultivation of these organisms.

The storage of river water in impounding reservoirs is not attended with the certainty—as some considered—of the pathogenic germs flourishing and increasing, thus constituting a menace to the community supplied by it. The doubt of the safety of such waters is after all a matter of degree, as it is improbable that any source of supply is theoretically free from the possibility of pollution. Take the Thames water which in past years has been supplied to London under far less favourable circumstances than now obtain as regards pollution. No outbreaks of disease have been traced to it.

Where there is a probability of contamination, and in order to reduce to a vanishing point the possibility of any pathogenic germs passing to the consumers, it is necessary to resort to filtration, and in judging whether filtration is requisite the engineer will be guided by the previous history of the water. A great amount of information on the effect of sand filtration is now available, notably the data published in the Massachusetts report, and also by Dr. Percy Frankland. It has been proved that efficient sand filtration will remove all but 2 or 3 per cent. of the micro-organisms, and this relates to the reduced number that have reached the filter after the destroying influences that have been referred to.

By constructing the filter so as to cultivate a nitrifying action there can be no question of the possibility of practically removing all germs. The best construction of a filter has to be considered in view of what it has to accomplish. If it has to remove finely-divided suspended matter which is not suspected of organic pollution, very fine sand under most circumstances would serve the purpose. In one case which the author is acquainted with, namely, the River Plate, this did not suffice, as the water contained a quantity of finely comminuted clay—giving the water a yellowish tint—which passed through the finest filter paper. A filter constructed of alternate layers of finely pulverised cinders and coarse sand was successful in arresting this matter. The efficiency of the filter was found to depend entirely on the fine cinders, even the absence of the dust caused a reduction of the efficiency. The experiments at Massachusetts established the fact that the chief bacteriological action takes place in the upper layer of filters. In the bottom inch there were but 3 per cent. of the number of bacteria that were present in the upper inch, and this has been found to be the case elsewhere. The conclusions drawn were, that with a 5ft. filter of coarse sand, ·06in. in diameter, about 30 per cent. of the bacteria could pass through. With sand of ·006in. diameter 14 per cent. passed. Very fine sand, 5 per cent. Garden soil, none. Experiments on the filters of the London companies indicate that the number of micro-organisms appear to be independent of the age of the filter-bed. If the cultivation of the germs has been once established it will continue, provided the supply of organic matter and of air is continued and the rate of filtration is regulated. If too fast, the purification is imperfect, as the nitrification of the organic matter would be arrested for want of oxygen. The cleansing of a sand filter interferes with its action, as the surface film has the most useful effect, and forms an essential part of the filter by arresting and cultivating the micro-organisms which pursue their functions of nitrifying the organic matters retained in the filter. Many filters have been constructed for dealing with the purification of sewage by utilising the action of micro-organisms, and they all point to a new departure in regard to the construction and the manipulation of filters in order to remove organic impurities. The subject is of so much interest and importance that it deserves the attention of all who are engaged in advising about water supply or sewage disposal.

## CATALOGUES.

S. A. Daniell, Birmingham. Illustrated Price List of Screwing Machines.

E. and E. Taylor, Limited, Finsbury Pavement, E.C. A neatly bound and well illustrated catalogue of hydraulic, steam, and hand power lifts, hydraulic pumping plants, wrought and cast iron ornamental work, iron buildings, &c.

Lancaster and Tonge. Handbook of their steam traps, and many other specialities.

O. Berend and Co., Fore-street, E.C. Price lists of Switches, Cut-outs, Resistances, and other accessories for Electric Light Installations, and their "A" list of "Daylight" Incandescent Lamps.

We have received from Mr. L. Casella a copy of a new catalogue of the very interesting and useful series of recording instruments for various purposes which have been devised by Messrs. Richard Frères, for whom Mr. L. P. Casella has been appointed agent in Great Britain, America, and the Colonies. These automatic recording instruments include various kinds for engineering, electrical, meteorological, and other purposes, speed recorders, speed indicators, recording pressure gauges, traction dynamometers, water level indicators, hydrographs, and others described in the carefully-compiled descriptive catalogue just issued.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

W. D. and S. (Cannon-street).—*W. Dickinson and Sons, Phœnix Ironworks, Blackburn; Hacking and Co., Bury, near Manchester; Thorpe and Priestley, Holmfield Mills, Bradford; J. Haigh and Sons, Priest Royd Ironworks, Huddersfield.*

W. F.—*The weight lost will be equal to that of the volume of water displaced. A cubic foot of iron might be disposed in various forms so as to displace different volumes of water, as, for example, in a solid block or in a very thin hollow cylinder.*

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*
*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)* .. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. .. .. £0 18s. 0d.
*Yearly* .. .. .. .. .. .. .. .. .. .. £1 16s. 0d.
Thick Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. .. .. £1 0s. 3d.
*Yearly* .. .. .. .. .. .. .. .. .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

### MEETINGS NEXT WEEK.

Geologists' Association.—Friday, November 2nd, in the Botanical Theatre, University College, Gower-street, W.C., at 8 p m. Lantern slides of geological interest will be exhibited by Mr. G. F. Harris, F.G.S.

### DEATH.

On the 22nd inst., at his residence, Cromwell House, Great Marlow, Edwin Clark, J.P., M.I.C.E., in his eighty-first year.

# THE ENGINEER.

*OCTOBER* 26, 1894.

## LOCOMOTIVES AND TRAINS.

Several correspondents have addressed letters to us in which they criticise the action of the North-Eastern Railway Company in using pilot engines with the fast trains from the North. Another correspondent says that he saw the Greater Britain used as a pilot or second engine with a train of moderate weight running from Carlisle to the South. All these gentlemen assert that either one engine is competent to do the work, or ought to be competent, or else that the use of two locomotives instead of one is rendered necessary by the faulty construction of the coaches, which are carried on six wheels instead of two bogies. So far as we know none of the correspondents with whom we are dealing possesses any special acquaintance with the conduct of railway traffic. They do not speak therefore as those with authority; yet the questions raised must not be dismissed lightly because of the position of those whose letters will be found on another page. Indeed, we are repeatedly asked why two locomotives are used when ostensibly one would do. The subject has only been re-opened by the Northallerton accident. The train from the North was, it will be remembered, drawn by two very powerful engines.

Now, if we consider the relations existing between locomotives, trains, and speeds, bringing to the consideration a competent knowledge of all the circumstances, it will quickly become apparent, we think, that there is some method in the madness of the railway companies, and that neither the locomotives, nor the locomotive superintendents, nor the coaching stock are to blame. The general public who write letters to the newspapers do not seem to understand that in nearly all cases, when very high speeds have to be maintained over long runs, a locomotive is as a rule taxed to its utmost capacity. We use the words in a special sense, which will be understood at once by railway men; nevertheless it may not be easy—or indeed possible—to make our meaning clear to those who have had no experience on the footplate of a locomotive. It is nothing to the point to urge that an engine has great cylinder capacity, a big boiler, and so on. The moment speeds approaching sixty miles an hour are required, we find that certain peculiar conditions are essential to success; and if these are not present, the required speed cannot be maintained. After a certain point has been reached it does not appear that in the matter of speed alone much is gained by augmenting the dimensions of an engine, provided the road is good and level, and the loads just those suited to the engine. Thus, for example, during the famous "race to the North" of a few years ago, Mr. Webb used old engines of the Lady of the Lake class to haul his trains of four 20-ton coaches to Crewe, about a distance of 156 miles, and they did the work admirably. But the addition of a fifth coach would have been fatal, and they could not possibly have satisfied the conditions on the line between Crewe and Carlisle; much more powerful engines were required for that work. It has been proved over and over again in this and many other countries, notably the United States, that for high-speed express work, the train ought not to weigh more than one and a-half times the weight of the engine and tender on comparatively level roads. On lines abounding in steep inclines, the weight of the train ought not greatly to exceed that of the engine and tender. To make a long run over a hilly road at high speed it is essential that the engine should get up the hills rapidly. Let us suppose that on a certain stretch of line it is known that an average speed of sixty miles an hour must be maintained. Let that length be ten miles, with inclines rising both ways and meeting in the middle. The total time allowed is ten minutes. If the climbing is done at, say, forty miles an hour, it will occupy 7·5 minutes, leaving only 2·5 minutes for the descent. The train would consequently have to climb five miles at forty miles an hour, and run down five miles at 120 miles an hour, which is an impossible thing. Mr. Ivatt, of the Great Southern and Western Railway of Ireland, prepared some years ago a table showing the effects on average speed of temporary reductions below the normal. The influence of such reductions is not fully or even partially appreciated save by those who have given train speeds much attention. In the case we have assumed, it may be taken for granted that the maximum allowable speed down grade would require four minutes for the five-mile run, or seventy-five miles an hour. This would leave six minutes for the climb, or fifty miles an hour; but it is nearly as difficult to get seventy-five miles an hour out of a train on a down grade as it is to get fifty miles an hour on the corresponding up grade. Indeed, an incline five miles long, so steep that an average speed of seventy-five miles an hour could easily be reached going down, would also be so steep that very considerable trouble would be experienced in getting up it at fifty miles an hour.

If our readers have followed us so far they will have little difficulty in following us further. The road out of Edinburgh is very steep and hilly. The public demand that the expresses from and to the North shall keep excellent time and travel at a very high speed. Now given a fine day with little wind and dry rails, we have no doubt that the North-Eastern engine attached to the train could have hauled it at the required speed and kept time; but the weather was not particularly fine—there was mist hanging about. Up to Darlington only one engine was put on. There a pilot was taken. The train was already late, and to prevent further delay it was imperative that there should be no delay or hesitation at climbing banks. One locomotive would possibly have sufficed for the work, but there was a doubt, and so a second engine was attached to the train. The desire of the district locomotive superintendent was that assurance should be made doubly sure, so he used two engines instead of one. There is not a line in the kingdom on which really high-speed trains are run over hilly country, on which double banking the locomotives is not practised from time to time. It constantly happens that a driver arrives at a station, and, seeing threatening weather, asks for and gets a pilot engine. This is, so to speak, a sacrifice to the laudable desire of the public for speed and punctuality. The case of the London and North-Western train from Carlisle goes for nothing, because for miles out of Carlisle the line climbs through a desperately difficult country until Shap Summit has been reached, and, in fact, the whole road from Carlisle to Oxenholme Junction is very trying to a locomotive. The Midland trains running over the Settle and Carlisle route are in a still worse plight. It is useless to urge that the inclines to be surmounted represent but a small portion of the road. The second engines demanded by the difficulties of four miles out of a hundred will have to run the whole hundred. The Board of Trade regulations are opposed to "banking" a passenger train, and it would have in any case to stop at the foot of the incline to take a pushing engine on. It will generally be found that pilot engines are only used under strictly exceptional circumstances when the roads are level. It is the presence of inclines that renders their use necessary. The fact that the road between Darlington and York is one of extremely easy gradients throws doubt on the assumption that the pilot engine was taken on because it was wanted. It seems far more probable that it was a light engine returning to York, and that it was run as a pilot, as is very often done, to avoid having a second "train on line."

It may be urged that an engine with 19in. cylinders, 26in. stroke, and 7ft. wheels, ought to be competent to run up very steep inclines with heavy trains. So it is, and at a good speed too, provided the weather is favourable. But good as the speed may be, it may not be quite fast enough, and two engines are used. We remember a running-shed foreman being once asked why he had sent out two locomotives with a certain train, and he replied: "I put on two because I had not one and a-half." We have not the least doubt but that there is a great superfluity of power on many trains criticised by our correspondents, but the locomotive superintendents no doubt hold, and properly hold, that it is much better that such a train as the East Coast express should have a great deal too much than a very little too little power. Our correspondents' contention that the East Coast coaching stock runs heavily requires direct confirmation by experiment. On the London and North-Western Company's lines a great deal of six-wheeled stock is in use, provided with traversing arrangements, by which easy running round curves is ensured. Long bogie stock runs very easily on good roads as far as the passengers are concerned, but we have yet to meet with a driver who holds that it is exceptionally easy to haul. Finally it may be admitted that it seems strange that two very powerful locomotives should be employed to haul not very heavy trains. Yet there is no cause for wonder when we consider the conditions. The worst that can be proved is, we think, that the district superintendent or traffic manager, or both, are over cautious. The principal reason for using two engines lies in the hilly nature of the road traversed, and the necessity of running up hill at high speed in order that down hill the speed should be kept within safe limits.

## SIR FREDERICK BRAMWELL AND TECHNICAL EDUCATION.

The distribution of prizes and certificates to the successful students at the Westminster Technical Institute during the sessions of 1893 and 1894 took place in the Westminster Town Hall on Monday evening. Sir Frederick Bramwell was on the platform, and he made a very excellent little speech. Sir Frederick, indeed, seldom makes a speech that is not worth hearing. Years ago he took a somewhat prominent part in the development of scientific education among the masses. There is reason to believe that matters have progressed faster and gone much further than he intended or even contemplated as possible. His own training and the nature of his pursuits has easily differentiated him from the modern school of professors, and he has evidently little sympathy with much that he sees and is probably expected to praise. It was, of course, essential that he should say what he could in favour of the work done by the Westminster Technical Institute, but that seems to have been little enough. He said that the students before him "had sufficiently proved their knowledge of the value of the institution to which they belonged by the fact that in four or five years their numbers had increased from 20 to 1000." Of course, the facts in no way justify the deduction. The most that they could prove is that a number of young men and their parents and guardians *believed* in the value of the Institution. Belief is certainly not knowledge; and no attempt was made by the students—or anyone else—to show what advantage had been gained by those who attended the classes. Sir Frederick went on to say that when he was a boy his master taught him all he could teach, and that embodied a good deal of practical work, without much theory. The fact was that theory was not taught by his master, because he had no theory to teach. What they had secured in the institutions of the present day was not only a substitute for what was imparted in bygone days, but included a great deal of information which could not formerly be obtained. They now saw why they did certain things, and why certain results followed. "Formerly they only did what they were taught, because their forefathers had done the same things for generations." We wonder whether any of his hearers drew the deduction from Sir Frederick's certainly not unsuccessful career that there is a good deal to be urged for the old-fashioned method. Sir Frederick went too far when he said that engineers did formerly, or at any time, certain things because their fathers had done them. Sir Frederick has lived long enough to have been personally acquainted with the men who turned the world upside down; and generations yet further back which included such men as James Watt, George Stephenson, Rennie, Telford and Maudslay, certainly cannot be accused of plodding blindly in the rut worn by their forefathers. Where in modern times can be found, as the product of the technical college or the Universities, men to compare with the giants of the past.

But although for a moment, and as much out of courtesy as perhaps for any other reason, Sir Frederick Bramwell exalted the modern method of education, his own good sense and keen appreciation of truth quickly brought him back to facts. He refused to admit that the men of a past generation who lived in the pre-technical education days, were the ignoramuses some persons would have us believe. "He was one of those," he said, "who believed that if, from generation to generation, good iron was made from the iron ore of a particular district by a certain process, it was better to follow that process than to depart from it at the bidding of a scientific man. Indeed, if a philosopher told him that that which had answered for generations was entirely wrong, he should begin to doubt whether the philosopher had not lost sight of a bit of his philosophy." Pregnant words these, which ought not to be readily forgotten by those who heard them. After this warning, Sir Frederick went on to praise the labours of the physicist. Once more we find evidence that he spoke against the grain. He was unable to name, or even suggest, any great benefit which had been recently conferred on humanity by the followers of pure science. The utmost that he could say reminds us of a story told of Dr. Johnson, who was asked by Boswell what was the use of a balloon. "Sir," replied Johnson, "You might as well ask what is the use of a baby. It may become a man." Sir Frederick warned his hearers not to despise the beginnings of science, however small, because they might give rise to great things. They should remember that it was not so very long ago when "a man in an Italian city found that, by a certain arrangement of metal plates, he could cause a frog's legs to kick. People then said, 'It might be wonderful; but what was the good of it?' Well, the good of it had since been amply demonstrated, and one of the illustrations of what might be got from a new scientific fact was to be found in the lighting up of that large hall by the incandescent electric light." This kind of claptrap is not worthy of Sir Frederick. "It is a far cry to Loch Awe." The distance between the electric light and Spalanzini's experiments with frogs is so great that the ordinary human mind cannot grasp it, and Sir Frederick did not stop to point out that the incandescent lighting of the hall owed its existence not at all to men of pure science, but to hard-working practical individuals, who did things first and left it to the professors to explain subsequently how they were done. Sir Frederick concluded with a lengthy reference to Professor Dewar's experiments on gases and the phenomena displayed by liquid air, and it is worthy of notice that he refused to commit himself to an expression of belief in the existence of absolute zero.

Such speeches as those made by Sir Frederick Bramwell cannot fail, we think, to do good, and help to recall people to their senses. But we should much like to hear a speech made by Sir Frederick out of the fulness of his heart, untrammelled by the necessity for saying more or less pretty things of the modern craze for "scientific" education. Concerning this craze as it affects other professions and callings we care but little. The relation which it bears to engineering is, however, quite another matter. In season and out of season we have insisted that engineering, either civil or mechanical, is not to be learned from books or in colleges or technical schools. A laboratory and a big testing machine never made engineers yet. On the 1st of October Mr. Lockhart Stephens read a paper before Guy's Hospital Physical Society on "Medical Education in Relation to General Practice." There is probably no education given in any profession which is so thorough, both as regards theory and practice, as that to be had in the great London medical schools. We cannot resist the temptation to quote a passage or two from Mr. Stephens' paper, so pertinent are they to the matter in hand:—"It is most important that the fundamental truths of natural philosophy should be known to all, for without such knowledge it is impossible for any man to study and practice his profession intelligently. A student who has been grounded in elementary science, commences his more special work with a mind trained to a proper habit of thought and prepared to follow the inductive reasoning upon which scientific medicine is founded. He has learned how to study such subjects as anatomy, and he has a knowledge of the sciences which are indispensable in attempting to study physiology." We have here a very excellent definition of the use of education in physical science, and if we substitute in the preceding passage for "anatomy," say mechanics, or for "physiology" say railroad work, the application will perhaps be more fully appreciated by our readers. Again, dealing with practical work, can anything be more to the point than the following passage:—"Take notes of your dissections, for in that way you will become possessed of a knowledge of anatomy which in after years will take you back—not to a particular page of Ellis or Gray, but to a part where you will have a clear mental picture of the actual structures. In practice, gentlemen, it is 'dissecting-room' anatomy, not merely 'text-book' anatomy you want, and the only way in which to acquire it is by direct original observation, by solid hard work, and by taking notes of your work. Read the preface to your Ellis: 'Its purpose is to teach the anatomy of the human body by dissection.' I am told that men no longer dissect as they used to do." Paraphrased this may mean, "In practice, gentlemen, it is workshop engineering you want, not text-book engineering." We can readily fancy how fully Sir Frederick Bramwell would agree with all that Mr. Lockhart Stephens had to say about thoroughness and practice.

Those who watch the signs of the times can scarcely fail to see that a change, a happy change, has begun to manifest itself in more directions than one. The pure physicist is no longer regarded as the proper man to teach engineering. There is to be noted a leaning in favour of men who have really practised the profession and know something of what work is outside a laboratory and a class-room. At one period not long past, it was held that the engineering firms, civil and mechanical, in Great Britain would receive with open arms the highly-trained product of the college. They did nothing of the kind. They pursued the even tenor of their way as though the Superior Young Man did not exist; and now we find it tacitly admitted, and even sometimes plainly asserted, that the most a college or a technical school can do is to prepare a young man to learn engineering. With this we have reason to be satisfied. But it must not be forgotten that putting our own efforts to make the truth known on one side, the result has been largely due to the outspokenness of more than one man who, like Sir Frederick Bramwell, is not only always sure of an audience, but certain that his words are competent to influence his hearers.

### RAILWAYS EXTENSION IN ASIATIC TURKEY.

The British Consul-General at Smyrna in a recent report draws attention to the complicated and important question of railway extension in Asiatic Turkey. Railway communication between Smyrna and the interior is in the hands of two British companies, the "Aïdin" and the "Cassaba," which are free from competition; but these lines extend only 240 miles inland, and a German syndicate has recently obtained a railway concession from Ismid, practically from the Bosphorus to Kharahissar and Konia, and eventually on to Baghdad, thus cutting off the two British lines from any extension E. and S.E. The bulk of the produce of Konia and the far interior line on arrival at Kharahissar will be transmitted to Smyrna. This opportunity is taken for renewing a previous recommendation as to the advantages of amalgamating the two British lines, and of warning the companies as to the danger of allowing minor interests to prevent an alliance which alone can secure the future success of both. The Aïdin Railway was the natural line of communication, because the short extension necessary from its present inland terminus at Diner to Chaï on the German line would pass through a comparatively level country, but the company failed to obtain a concession for such extension. The Cassaba Railway would require to construct a longer branch from its inland terminus at Alashehir to Kharahissar on the German line, which would pass over a mountainous country, involving heavy gradients, and probably costing three times as much as the former route. A concession for this extension has been granted to a French syndicate, which has concluded a provisional agreement with the Cassaba Company to purchase their line at any time before the end of July, a date subsequently extended. If the two British companies could arrange for an amalgamation of their interests, the French syndicate would gladly join them, and means be found for adopting the cheaper, more convenient, and direct route to Chaï. This would get rid of the one drawback to the Aïdin line—the heavy gradients and narrow tunnel in its Ephesus section, which could be avoided by a short branch connecting the two railways. Though the German company will have no option as to the transport of a large proportion of its freight to Smyrna, it will be able to impose onerous terms on the new French company, burdened with the excessive cost of the mountain extension, by holding over it the threat of an extension of the Aïdin line to Chaï, and a transference of their traffic to the rival line. Another view of the question worth considering is—sooner or later, the Aïdin Company will obtain the concession for its natural extension to Chaï, but if the proposed Kharahissar extension of the Cassaba Railway be carried out, it is very doubtful how far two competing companies, supplemented to a certain extent by the competition of a third company running to Ismid, will find sufficient traffic to pay reasonable interest on three separate large capitals. The German company and the new French syndicate have obtained from the Porte guaranteed traffic of from £500 to £800 per mile, and in view of the competition that will ensue, the Ottoman Government will have to contribute annually large sums to each of these companies. The Aïdin Company, which will be the only British line connected with Smyrna, has no guarantee of this kind, and the Chaï extension will be too short to render one of any value. It therefore appears that the suggested amalgamation is more desirable than ever for the interests of all concerned. It is not too late for amalgamation, as difficulties are bound to arise in obtaining the large capital required, and the advantages of a coalition will duly become more obvious to the supporters of the French syndicate.

### COTTON MACHINERY FOR CHINA.

It is being asserted by commercial authorities supposed to be informed that one of the main effects of the present war in China, when the country gets rid of its invaders, will be a considerable change in the disposition of that Empire towards Western civilisation, and a determination to cast off the prejudice which has hitherto militated against her material prosperity. British machinists and engineering firms will greatly benefit, from a trade point of sense, if these expectations should be realised. Meantime it is instructive to notice the advance which, prior to the war, China was making as a purchaser of cotton machinery from the engineering workshops of this country. Four years ago the Chinese Government granted to one of the native firms a monopoly for ten years of the spinning and weaving industries. The monopoly is not without its points of discord. The original mill has recently been destroyed by fire, and the proprietors of the monopoly now insist that the close period should date from the time the reconstructed mill starts working. While the authorities have not yet come to a final decision, companies are being formed in various parts of North China to erect and work mills under royalty from the original possessors. Some difficulty is arising, however, in several instances from some hitch in getting the contracts for the machinery, entered into a few months back, executed. Payment was to extend over four years, and some of our engineers do not seem disposed to allow so long a credit. But the Chinese are hoping that the improvement lately observable in exchange will assist in getting the orders that are pending for machinery put through.

## LITERATURE.

*A Practical Handbook of Drawing for Modern Methods of Reproduction.* By Charles G. Harper. London: Chapman and Hall. 1894.

One of the most prominent developments of the last quarter of this century is the "illustrator." He need not be an artist, and generally he is not. Very often he is not even a trained draughtsman. But he must be "picturesque" in a curious popular sense, and "effective." It is not easy to account for his existence. Whether he is a result of the great increase in periodical literature, or of the simplification and extension of photographic processes, is not clear. Perhaps he owes something to both, and it is probably not too much to say that there would not now be so many illustrated papers and magazines if it were not for the existence of the "illustrator," and the ease and rapidity with which his work can be reproduced. Five-and-twenty years ago the relief printer was dependent upon the wood engraver for his pictures. For intaglio printing we had only engraving in its varieties, line and stipple produced by the burin, mezzotint by the scraper, and the bitten line of the etched plate. As an intermediate process there was lithography. In all we had the personal style and feeling of the engraver. Now nearly everything is superseded by photographic reproduction, by "process" as it is aptly called. On all sides men and women, young and old, are eager to become illustrators. As Mr. Harper says, "Never was illustration so marketable as now, and the correspondence editors of the Sunday papers have at length found a new outlet for the superfluous energies of their eager querists in advising them to 'go in' for black and white, as one might advise an applicant to adventure upon a commercial undertaking."

At first sight it is not quite easy to grasp the author's position, or why the book came to be written. Mr. Harper points out that drawing for reproduction should mean a good deal more than the staining of paper, and he is certainly not deficient in criticisms of contemporary draughtsmen, some of which, we think, is deserved; but with all this he explains in detail the mechanical side, and dwells on the mechanical resources and tricks open to the man who presumably is not an artist, the air brush and the manufacture of dots and "splatter work" with a tooth brush and a match stick. He seems to wish the illustrator to be an artist and to be trained as such, and yet by his book he has apparently sought to provide the impossible, a royal road to art. But it may be that he considers a knowledge of the various processes as useful to the artist as to the illustrator, and so it is.

The book contains a sufficiently detailed description of the gelatine, albumen and bitumen processes, and has useful notes on paper, pens and ink. We cannot congratulate the author upon all his illustrations; some are quite unworthy of the book. We are sorry to see that he supports the practice of *retroussage* in printing the etched plate. No doubt a good deal of bad etching can be disguised by skilful *retroussage*, but that is no reason for approval of the practice. The old masters did not rely on *retroussage* to adorn their drawings. Again, we think that he underrates the importance of line, and does not dwell enough upon form and value. No one can be said to be an artist who is not a master of the three. The illustrator of to-day indulges in his own conventions, because as a rule he is not able for more. We may accept them because, as a rule, we can discover what he means to express by them, but do not let him complain if we decline to accept them as of art.

*Electricity in the Service of Man.* By R. Wormell, D.Sc., M.A. Revised and enlarged by R. W. Walmsley, D.Sc. London: Cassell and Company. 1894.

This work is intended as a popular and practical treatise on the application of electricity in modern life. If the process of sifting is of advantage the present volume should only retain the valuable portion of earlier works. Its history is as follows:—A popular treatise was brought out some years ago in German by Dr. A. R. von Urbanitzky, and was considered so useful that a translation into English was made by Mr. Emil Beyer for the present publishers. This translation was placed in the hands of Dr. Wormell, who found that in order to adapt it to English readers somewhat extensive alterations were needed. All the autobiographical notices were excised, but the general plan of the work was retained, and the first edition was published in 1888. In 1890 further changes were rendered necessary owing to the improvements in the science, and Dr. Walmsley added appendices on dynamos and transformers. The present volume, which may be considered as the third edition, differs considerably from the earlier editions. Dr. Walmsley has excised 120 pages, and substituted about 200 pages of new matter, so that he is responsible for about 240 pages out of a total of 976 pages. The system upon which the book is written is first the historical treatment of the subject, and then the description of the applications of electricity to industrial life.

The volume has more than 950 illustrations, most of which are very good. In the original no formulæ or mathematical expressions of any kind were used, but the English editors have added simple expressions for many of their descriptions, and we think this increases the value of the work even from a popular point of view. Hydraulic analogies are skilfully used to explain the theory of resistance and potential, and it seems to us that when not pushed too far such analogies assist materially in the comprehension of electrical science. We expected in a book of this class to find descriptions of a good many antiquated apparatus and machines, but we have been agreeably surprised to find that Dr. Walmsley has been very careful to leave out a good deal of matter which appears time after time in most books intended to popularise the knowledge of electrical science. The matter relating to high tension currents, and the apparatus employed in producing such currents, is brought well up to date by clear descriptions of Tesla's experiments and Elihu Thomson's work. The dynamos described exhibit a very catholic taste on the part of the authors, German, French, and American machines being as well represented as British types. Three phase machines are illustrated and described, and the somewhat difficult problem of polyphase winding is described as simply as is possible.

The second part of the book consists of two divisions—(1) The Generation and Conduction of Electricity, and (2) Practical Applications of Electricity. The woodcuts of the commutators used upon the various types of machines are very well drawn, and the explanations are clear.

Diagrams of developed windings are also given, which are much more readily intelligible than the complicated wound diagrams found in some works. In his description of cells, the author alludes to the Fuller type, and states that about 20,000 of these are in use in the English telegraph department. We believe that primary cells are being done away with now as far as possible, and that their place is being taken by dynamos, as is usual in the United States.

Dealing with the question of photometry, the author describes Mr. Vernon Harcourt's "Pentane" standard, and expresses the wish that it may become a legal standard. We endorse this view as to a legal standard being eminently desirable, but the difficulty of comparing differently coloured lights will always be present. It is almost impossible to compare the light of the arc lamp with any of the ordinary standards at present in use. Descriptions are given of various electric railways, and also of the telpherage system. If Prof. Fleeming Jenkin had not died prematurely, this system would doubtless have received more applications than it has yet had. Considerable space is devoted to the description of telephones and microphones. The book closes with a chapter upon telegraphy. The work covers a very wide range, and is about the best popular account of the subject we have seen.

*Boiler Construction and Useful Information for Practical Men.* By W. D. Cruickshank, Chief Engineer Surveyor N. S. W. Government. 1894.

This book is produced by Messrs. Batson and Co., of Sydney. The type and paper are indifferent, and in our copy several corrections have been made with pen and ink; the plates are crude; and as the book contains only about 250 pages including the plates, and costs 6s. in Australia, it will be seen that in the matter of publishing there is room for considerable improvement in that colony. The work, however, is intended to meet generally the wants of those who cannot afford *editions de luxe*, the artisan, working mechanic, and foreman, and to put before him in language he will readily understand the leading principles and practice of boiler construction. We may say at once that these conditions are very ably fulfilled. Mr. Cruickshank has evidently been through the mill, and is therefore from experience in a position to give exactly the kind of information required by his intended readers. The book is divided into paragraphs to which an index gives reference, and not into chapters. It commences with a few leading notes on the nature and strength of iron and steel; the stresses in a plain cylindrical shell are then explained, and we must call the author's attention to the misleading use of the term "internal surface," when it is evident the "cross sectional area" is what is meant. The fault occurs several times, and renders passages otherwise clearly and correctly expressed almost unintelligible.

Into the matter of flues Mr. Cruickshank has gone very thoroughly; he discusses the relative strengths and suitability of all the modern flues, giving and explaining the formulæ, and making just and judicious remarks about the unfortunate difference of opinion between the Board of Trade and Lloyd's as to the diameter to be taken in these calculations. He says:—"There is no doubt that both Lloyd's and the Board of Trade are quite prepared, from their own point of view, to support and defend their action, but to practical minds of ordinary perception, it is questionable if the soundness of the logic used would be very apparent or of a convincing character."

In speaking of red-hot boiler flues the author expresses his opinion with characteristic colonial positiveness He considers an explosion from such a cause an impossibility, basing his arguments on the Lavington-Fletcher experiments. We would call his attention to Thurston's remarks and conclusions on the same matter, which will be found on pages 573-4 in his book on boiler construction. The staying of flat surfaces, and particularly furnace crowns, is then gone into by calculation and graphical construction in a satisfactory manner; and there follows a systematic, lucid, and exhaustive description of the various methods of riveting plates together. This section is conveniently epitomised in the end of the book by a number of plates illustrating the types of riveting, and each accompanied by its "personal equation."

The author's part of the work finishes with a short and not very able discussion on water-tube boilers. In this matter Mr. Cruickshank is not quite up to date—his forte evidently lies in marine boilers, Scotch type. Ordinary pattern land boilers are scarcely noticed, and locomotive boilers are passed by entirely. The letterpress concludes with a list of "the rules which govern the construction of machinery in this country," to which are added Lloyd's rules for reference. A table of areas and circumferences is also given. In conclusion, we can confidently recommend this book to the practical man; it is written on the whole clearly and well, and fills a place which no other work we know of exactly fits.

*The Electric Transformation of Power.* By Philip Atkinson, A.M., Ph.D. London: Crosby Lockwood and Son. 1894.

Mr. Atkinson's work is intended as a popular treatise on the electric transformation of power, and its application by the electric motor, including electric railway construction; and it is written in non-technical language. All historical matter has been excluded, as well as descriptions of experimental apparatus; only the latest and most approved methods are stated by the author to be referred to. The preface is dated from Chicago, and the work is published in New York as well as in London. All the matter appears to refer to American practice; the book is well printed, and the cuts are better than in most popular treatises.

The author describes a number of well-known types of American motors, giving, in some cases, details as to the winding; and then deals with the Tesla alternating current motor, and other recent types. He succeeds in giving a good general idea of the apparatus, and then passes on to the application of the stationary motor. These applications are very numerous in the United States, electric elevators, electric fans, and windlasses being much more commonly used than in Great Britain. The subject of electric railways and railway motors is then treated, and the working parts—such as poles, trolleys, insulators, and switches—well described. The motors themselves are well illustrated, and the author appears to consider that as the double reduction gear was given up in favour of single reduction, so the latter will be superseded by the gearless motors, of which he illustrates the Short type.

Central station work is described with special allusion to the power plants used in Chicago. The work has very few references to British work; in fact, two paragraphs, dealing respectively with the Liverpool overhead railway and the City and South London Railway, are the only cases we have noticed. To the ordinary non-technical reader in this country, this is a decided disadvantage; and the technical reader would desire fuller information on American practice than is here given.

*Applied Mechanics: An Elementary Manual on.* By Andrew Jamieson, M. Inst. C.E. London: Charles Griffin and Co. 8vo. 1894.

Although this manual has been written expressly for first-year students of applied mechanics under the Science and Art, the City and Guilds, and other bodies, it is one of those books that make us feel that there are many things which can be learned much more easily from some of the books of to-day than they could when we were at school. Mr. Jamieson has the faculty of selecting from amongst what may be called the old problems in such a way as to illustrate their solution and application by reference to familiar and useful modern practical examples, and he has made use of this faculty as he has previously done in his books on the steam engine which we had pleasure in noticing very favourably. The book is turned out in the satisfactory style usual with Messrs. Griffin.

## BOOKS RECEIVED.

*Geometrical Conics.* By Charles Smith, M.A. London: Macmillan and Company.

*The Construction of the Modern Locomotive.* By George Hughes. London: E. and F. N. Spon. 1894.

*The Slide Rule.* A practical manual. By Charles N. Packworth. Manchester and London: Emmott and Company.

*Elements of Metallurgy.* By W. Jerome Harrison, F.G.S., and William J. Harrison, jun. London: Blackie and Son. 1894.

*Specifications for the Use of Surveyors, Architects, Engineers, and Builders.* By J. Leaning, F.S.I. London: Sampson, Low, Marston, and Company. 1894.

*The British Fleet. The Growth, Achievements, and Duties of the Navy of the Empire.* By Commander Charles N. Robinson, R.N. London: George Bell and Sons. 1894.

*The Electric Current, how Produced and how Used.* By R. Mullineux Walmsley, D.Sc. (Lond.), F.R.S.E., &c. With 379 illustrations. London: Cassell and Company. 1894.

*The Durham College of Science, Newcastle-upon-Tyne, Calendar, Session* 1894-95. London and Newcastle-on-Tyne: Andrew Reid and Company. London: Whittaker and Co. 1894.

*The Decoration of Metals: Chasing, Repoussé, and Saw-piercing.* By John Harrison. With 180 illustrations of works by various artists and original designs. London: Chapman and Hall. 1894.

*The "Practical Engineer" Pocket-book and Diary*, 1895. Edited by W. H. Fowler, Wh. Sc., M. Inst. M.E., Assoc. M. Inst. C.E. Manchester: Technical Publishing Company; London: John Heywood.

*Annual Report of the Board of Regents of the Smithsonian Institution, showing the Operations, Expenditures, and Condition of the Institution to July*, 1892. Washington: Government Printing-office. 1893.

*The New Tariff of the United States, with the Necessary Consular Instructions and Regulations, Money Conversion, Tables, Names of United States Consular Offices, List of Ports, &c. &c.* London: *Shipping World* Office. 1894.

## EDWIN CLARK.

Mr. Edwin Clark, M.I.C.E., whose name is associated with the Britannia and Conway bridges, and will be ever associated with the rise and development of large girder bridge construction, died at Cromwell House, Marlow, on Monday night. He was born at Marlow in 1814, and after the usual school-days and apprenticeship, he became associated with several of the English engineers. He worked under Robert Stephenson, and as resident engineer had control of the construction of the Britannia Tubular Bridge, his brother, Mr. Latimer Clark, being appointed his assistant. After the completion of the Britannia and Conway bridges, he wrote the well-known book on these structures, to which the whole world looked as the greatest engineering feats to that date. He was assisted by his brother Latimer in this work, which was published in 1850. The Britannia bridge was begun in May, 1846, the first of the great tubes lifted on the 23rd June, 1849, and the first locomotive ran through in 1850. He was associated with Fairbairn, and carried out under him the celebrated experiments on the strength of materials, and of girders and girder tubes. He delivered a lecture on these bridges in Marlow in 1881. He was elected an Associate of the Institution in December, 1850, and was transferred to the class of member in April, 1855. He contributed papers to the "Proceedings," Institution of Civil Engineers, on "Hydraulic Lifting Graving Docks," in 1866, and on "Engineering Philosophy and the Durability of Materials," in vol. xxvi., in 1868, the latter containing some important references to telegraph work and insulating materials.

For many years he was chief engineer to the Electric Telegraph Company, and an interesting pamphlet exists describing his proposals for signalling by electricity on the London and North-Western Railway. He patented the hydraulic graving dock and the hydraulic canal lift, and was inventor of the block system of railway signalling. He constructed the famous harbour of Callao, in Peru, and carried out engineering works in various parts of the world, and in connection with the Anderton canal lift an important report by him exists on the causes of failure of some of the great lift cylinders in 1882. Retiring in 1876, he settled down at Marlow. Mr. Clark was a keen student of astronomy, and was a Fellow of the Royal Astronomical and Meteorological Societies.

## TEN-HORSE POWER COMPOUND TRACTION ENGINE.

Few of our readers are aware of the expense incurred by the proprietors of travelling merry-go-rounds in the purchase of their plants. The quantity of stuff to be frequently moved is very large. Thus, "Hancock's Great West of England Steam Switchback" requires five immense road wagons for its conveyance from place to place. The proprietors of these shows have found that it is very much cheaper to employ steam than horses to do the hauling, and they regard the traction engine as an important feature in their display. Messrs. Charles Burrell and Sons, of Thetford, have supplied several traction engines of this kind, the finish of which is as good as it possibly can be made. As these engines have to work through all kinds of hilly country they must be excellent. Thus, on one occasion a run was made from Poole to Weymouth, with a heavy load, and the thirty miles were covered in eight hours, or, excluding stoppage for dinners, seven hours and a-half. Starting from Poole at 8 a.m., the engine arrived at Weymouth Esplanade at 4 p.m.

Messrs. Hancock Brothers, of Bristol, purchased an 8-horse power engine at the Doncaster Show in 1891 from Messrs. Burrell, and that which we illustrate has recently been delivered to the same firm.

We have already fully illustrated and described in detail Messrs. Burrell's system of compounding, which consists in using one crosshead for the two piston-rods, and consequently we need not go over old ground. The new engine was specially built to order. The dimensions of the 10-H.P. engine are as follows:—Diameter of cylinders, 7in. and 11½in. by 12in. stroke; driving wheel, 6ft. 6in. diameter by 18in. wide; front wheels, 4ft. 1½in. diameter by 12in. wide; hind tank holds 178 gallons; front tank holds 125 gallons. The engine is exceedingly strong. The working pressure is 150 lb., and the finish is in all respects equal to that of a first-class railway locomotive.

## ELECTRICITY IN WIRE MILLS.

The President, Alderman Thomas Richardson, B.A., of the North-East Coast Institute of Engineers and Shipbuilders, delivered his address on the 16th inst. It was mainly devoted to the subject of "Electricity as a Power Transmitter." In the course of his address he said that an example of what may be termed ideal electrical driving is that of the Bedson Wire Company, of Middlesbrough, where the installation is the most perfect and complete that has as yet been attempted in this country. Every process connected with the manufacture of wire is carried out by means of electricity, the wire drawing, galvanising, spinning, and barb fencing machines, overhead and locomotive cranes, hydraulic pumps, induced draught fans, lathes, centrifugal pump, are all independently driven by electric motors. Owing to the entire absence of shafting and belting the construction of the building is very light, and the convenience of the whole plant is most noticeable. The current is generated by a 600-horse power dynamo, driven direct by a three-crank triple condensing engine with boiler of 160 lb pressure. A special tunnel, 350 yards in length, has been constructed for the conveyance of the conductors, and branches are taken from these to the 50 motors which vary from 5 to 40-horse power each. The lighting of the works is most complete, the greater part being carried out on the inverted arc principle, which is so perfect that there is an entire absence of shadows. The original plans for driving these works electrically were prepared by Mr. Selby Bigge, who appears to have given considerable attention to the question of electric driving. Before definitely deciding to put down such a novel plant several experiments were necessary, for which purpose special machines were designed by Mr. Bedson, the managing director of the Bedson Wire Company. These experiments were made at Liége by Mr. H. Pieper, and were so successful that after an exhaustive series of tests the directors of the company decided to adopt the electrical installation in its entirety.

A novel feature in connection with the boilers at Messrs. Benson's works is the application of Messrs. Ellis and Eaves' well-known system of induced draught. This is the second application of the system to land boilers, the first having been made at the Atlas Works, Sheffield, originally arranged with Lancashire boilers. These have gradually been replaced by ten single-ended boilers of the marine type, the advantages claimed being as follows:—(1) Considerable economy compared with the Lancashire boilers with Galloway tubes. (2) Considerable reduction in space occupied. (3) Absence of smoke. (4) Greater elasticity of power. In ordinary work, by maintaining a vacuum of 3in. at the fan, the combustion is at the rate of about 35 lb. per square foot of grate surface, and one single-ended boiler can readily evaporate as much steam as three Lancashire boilers 27ft. by 7ft., with ordinary chimney draught. Where the demand for steam varies in a works, the system is a great convenience, and this is especially the case for electric light installations. It is evident that with this system of draught, or with any other efficient system, the assumed consumption of 13 tons per day could be still further reduced.

The Iron Trade in Staffordshire.—In 1830 there were 123 blast furnaces in Staffordshire, producing 212,000 tons of pig iron; in 1872 there were 212 furnaces, producing 950,000 tons. In 1879 the furnaces had fallen in number to 181, and to 105 in 1893, of which only 39 were in operation, producing only a little over 500,000 tons. In the last fifteen years the puddling furnaces have gone down from 1577 to 900, and the production of certain forms of wrought iron from nearly 1,000,000 to 560,000 tons. But the furnaces at work are much larger than formerly, and the diminution of iron has more than made up by the growth of steel.

"Made in Germany."—A correspondent writes to the *Birmingham Daily Post* on the effect which the Merchandise Marks Act has had on the demand for goods "made in Germany." He maintains that the passage of the Act has simply had the effect of enabling British shippers to buy German goods and ship them direct to the Colonies instead of bringing them to the Thames and then re-shipping them—in other words, of transferring the carrying trade from England to Germany. "The idea of the sentimentalists who urged the passage of the Act," he says, "appears to have been that when goods were once marked 'German' or 'French' the English buyer would reject them. The English buyer is not such a fool. He may be surprised to find that articles he once accepted as English are of foreign make, but that he will pay any more for English than for foreign is simply a trade union fiction. It may serve for the platform. Unfortunately, it does; but there is no room for sentimentalism in business. The 'made in Germany' mark has proved a splendid advertisement for Deutschland. I first became aware that some kinds of lithography were done more cheaply in Germany than in England by seeing the mark upon the Christmas cards of a leading firm of stationers. The English printers have only had 'odd jobs' from me since. In the course of many years' trading I have often found myself beaten in price by my competitors. I had sought out, as I believed, the best markets, I had reduced everything to a minimum; but still I was beaten. A few months ago I was asked to quote for a certain article, of which I had for years lost the sale. A sample being sent me, I took it carefully to pieces for calculations. In doing so I found one of the parts—an important part—concealed in the finished article bore the ominous legend, 'Made in Germany.' The mystery was explained. I soon visited the Fatherland, and have now recovered my orders. Not only so, but I am procuring other similar articles from the Germans, much to my own benefit."

## INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND.

### INTRODUCTORY ADDRESS.*

By Mr. John Inglis, President.

At this year's session of the British Association, the learned President of Section G recorded the opinion that Presidential addresses were in the nature of them almost immoral, and fit only to be abolished. It is always delightful to find one's own crude and unshapen thoughts expressed with vigour and precision by a master, and, in all my recent reading, nothing has more nearly attained to the ideal of the word in season, meeting my eye, as it did, just as I had awakened to the near approach of the thirty-eighth series of the meetings of this Institution. But though fortified in no small degree by the opinion quoted above, I have scarcely courage sufficient to introduce, all at once, so startling a change into our programme as the entire suppression of the remarks which, in accordance with usage, are expected from the chair at the opening of the session; and I propose to effect a sort of compromise by being somewhat brief on the present occasion, and in this also I follow the custom of most of my predecessors in their second year of office.

The Institution, I am glad to say, continues still in a flourishing condition, the numbers on the roll steadily increase, and there is no falling off in the interest of the members in its proceedings. Our short honorary list has been recently adorned by the name of the Director of Naval Construction, Dr. W. H. White, who worthily represents the profession of naval architecture. On the other hand, the name of the illustrious Helmholz disappears from among those of our honorary members, his death having taken place last month; and in December, 1893, Professor John Tyndall's decease was hastened by misadventure. Our obituary also contains the name of a Past President and most distinguished engineer, Mr. James Reid, whose busy life was suddenly closed during a short and well-earned holiday. Mr. Reid's addresses, while he held office, are among the most important of the contributions to our transactions, and display an exhaustive knowledge of the history of that branch of engineering wherein he made his reputation. The deceased members and associates are Mr. David Henderson, equally well known and esteemed as shipowner and shipbuilder; Sir Archibald Orr Ewing, Mr. John Morgan, and Mr. William M'Ivor Morrison.

The Institution work of last session may fairly be considered of much interest and value. A timely paper by Professor Biles, on "The Strength of Large Ships," is apparently, from its tenor, the first instalment of a lengthy contribution on this subject; and, doubtless, we may confidently expect, although it is not yet announced, that the learned Professor will follow his very complete statement of the strains to which large ships may be liable, by an equally complete exposition of the manner in which these strains are to be met, showing the most advantageous disposition of material in the structure. The elaborate paper by Mr. Arnot evoked one of the liveliest discussions ever heard within these walls, and one which has, for some time at least, delivered us from the reproach, often levelled at similar societies, of being conducted on the principle of mutual admiration. To the authors of some of the shorter papers, and to those who may have material by them for other short papers, I desire to offer a word of encouragement. The importance of a new invention or mechanical arrangement is hardly to be estimated by the number of words required to describe it. An epoch-making invention is indeed a rarity, and the birth of Minerva is in no way typical of the appearance of those contrivances which have wrought such mighty changes in the industrial world. There is probably no machine of any consequence which is not the sum of many successive increments of invention or discovery, and the product of the ability and efforts of many workers. It is on evidence that the ingenious spinning machinery, now in common use, is a compound of about eight hundred different inventions. How minute some of them must have been, and yet how indispensable.

Precisely because the progress of invention is, as a rule, made by short steps, and in obedience to necessity, which is the mother of it, the most notable inventors have, as a rule, not been "scientific men;" that is to say, men exclusively engaged in scientific research, as distinguished from those mainly occupied with commerce or manufactures. (A brilliant exception to this rule will at once occur to all Glasgow men, but there is only one Lord Kelvin.) The continual desire to strengthen the weak parts of an industrial process directs the minds of many eager searchers to contrivance, until to one a fortunate solution presents itself, and invention is carried forward another pace. Therefore, the diffidence that would make us hesitate to bring forward improvements because they do not appear sufficiently imposing, or because we may not be able to clothe our thoughts in words at once elegant and exact, is out of place among the members of this Institution. It must not be forgotten that one of our objects is discussion, and the salient points of a communication are more readily seized when they are few.

I have, though not without an effort, resisted the temptation to provide myself with a subject for this evening out of some of the remarks on ocean steamers made when I had the honour of addressing you twelve months ago. Adverse criticism is always stimulating, and I am far from complaining of it; but it was surprising to find what I introduced as a mere reference, or illustration, taken as the main subject of discourse, and an attempt to do justice to the past treated as a discouragement of progress in the future. We cannot but admire the enterprise and sagacity shown by the moving spirits of the great shipowning companies at home and abroad, and we must admit that it is not by a timid and shrinking policy that great industrial revolutions are carried out. It is an axiom, that he who never makes a failure never makes anything; and, in like manner, the cautious seeker after safe investments is not, as a rule, the pioneer of civilisation, or the organiser of new outlets for industry. But while we look with pride at our mercantile marine, its prodigious capacity for transport, the excellence of its construction, and the skill with which its movements are directed, there is no irreverence in watching carefully for the appearance of any policy which may endanger its prosperity. The profitableness of navigation is therefore a legitimate subject of inquiry to the scientific shipbuilder, whose methods may very possibly yield results not easily obtained by the unaided commercial expert. It is but a few weeks ago that one of the most able of administrators of shipowning enterprise publicly admitted that ships, of the type of the most recent addition to his fleet, could not be made commercially successful without the aid of a Post-office subsidy for mail carrying. It would be presumptuous to claim Sir Thomas Sutherland as a convert, or even to suppose that his mind on the subject had only been recently made up. I merely quote his dictum as an emphatic termination to the existence of any difference of opinion on this question which may have hitherto survived. The question of the profitableness, or, as many would prefer to say, the unprofitableness, of shipping in general, is but part of the larger question, the condition of the world's trade; and for that depression which is at present all but world-wide, there are many who consider that no small part of the responsibility lies on the makers of all kinds of machines for the saving of labour. According to one of the most prominent of continental steamship directors, "the engineer has gotten the better of the man of business;" and if this be true, and of general application, it is surely a very serious reflection for us who hope to earn a living by continuing to furnish labour-saving appliances. All the pessimists are, however, not of one mind, and various are the causes assigned for the present slackness of demand for our wares, and the abasement of ocean freights. Monometallism, labour disturbances, the private ownership of land and minerals, as well as over-production, are favourite suggestions of those disposed to take sombre views of the future. The optimist, on the other hand, points to recurrences of periods of good and bad trade, and talks of cycles and the swing of the pendulum; but, while it is pleasant to believe in him, we cannot altogether disregard the exceptional position among the ages of the century now nearing its close. It has seen the application, on a great scale, of steam to what are still called manufactures, and to locomotion, the peopling by civilised races of America, Australasia, and much of Africa, the spread and consolidation of our empire in India, the opening to commerce of China and Japan, and the shortening of trade routes to the East by means of the Suez Canal. That is to say, it has been a time of extraordinary increase of activity in production, of simultaneous increase of demand for commodities, and of the means of transporting these to great distances at small cost. Another so momentous a change in the aspect of the world, as the last three generations have witnessed, is hardly within the bounds of probability. Therefore, without being either alarmist or pessimist, one may feel some anxiety as to the future of those who depend on the continued absorption of the products of modern industrial appliances, and may decline to be quieted by the assurance that history repeats itself, and that what has been will be.

As concerns the use of this or that metal in coinage, it is difficult to see how the fixing by law of the relative values in exchange of any two or more substances could bring about a general increase of wealth and prosperity; and, having seen periods of good and bad trade, without any coincident alterations in the standards, I am of those who have no faith whatever in bi-metallism as a cure for the ills from which commerce now suffers.

The disastrous effects of labour troubles are too obvious to require demonstration, and the guilt of those who, from ignorance, prejudice, or self-interest, foment disputes in the labour market, is none the less manifest and heinous because it is not recognised by the law. But, as the abolition of all suspensions of industry by labour wars would result in still greater production, those who strive to promote industrial peace must still reckon with those who maintain that there is too much activity in production already.

I hasten to allay the uneasiness you may possibly feel as to any intention of mine to discuss the systems of land tenure in this country, or their effects upon the home or foreign trade. I shall say no more than that I believe the usages connected with the occupation of land have yet to be completely adapted to the new environment, of which modern mechanical appliances are mainly the cause, and that this adaptation, like all radical changes, will probably continue to be attended by much suffering to individuals.

The complaint of over-production is by no means easy to dispose of. It formed the subject of one of Carlyle's eloquent chapters half a century ago, when the sum total of production was a mere fraction of what it is to-day; and, indeed, it is not difficult to be both eloquent and impressive about over-stocked warehouses, and the destitution which surrounds them—about "the frightful overplus of shirts" and "the millions of bare backs." It is all very well to take refuge in epigram, and say that over-production is only a synonym for bad distribution, and when the blocks in the channels of distribution are removed all will be well; but the satisfaction to be thus derived is by no means substantial or enduring. Not that there is any lack of proposals for the amelioration of the world, in regard to the distribution of its goods. Dynamite, as an agent for the regeneration of society, has its advocates, and scarcely more reasonable are the leather-lunged preachers of the pillage of the rich, with or without legislative sanction—these we may leave to the police; but when one of the loudest of the orators from Hyde Park platforms speaks of Labour as crucified between two thieves—Capital and Machinery—our attention is arrested by this assailing of our craft. We can imagine the applause with which this sounding figure of speech would be received by even the respectable portion of the listeners, who doubtless, in a vague way, felt themselves flattered by being compared with the central figure in the great tragedy; but it was probably far from the speaker's intention to convey to his audience that when labour suffers, capital and machinery suffer with it. Such as he have usually no compassion to spare, except for those with whom they are bound *ex officio* to sympathise. What he wished to enforce was that the condition of labour, that is of the bulk of the people, was made not better, but worse, by the presence of capital and machinery. And this is the argument, not only of hysterical members for labour, but also of sober and studious economists, who, if they were to push their theories to a logical conclusion, would deprive us of all implements and devices, by the aid of which we have, as a race, emerged from the savage state of our remote ancestors. "Arms and the man," says Carlyle, "is no longer the epic of this world," tools and the man has taken its place;" and can we believe that the perfecting of tools, which is the engineer's business, is pernicious to the general interest? The truth about the matter I believe to be that the condition of things, which we agree to call over-production or depression of trade, is not primarily due to machinery, but in a great measure to the reckless borrowing by impecunious States, communities, and associations, encouraged by the imprudence of financiers, and the credulity of the public as to the powers of Governments and other debtors to fulfil their obligations. The abnormal and unwarranted demand for goods from those put in easy possession of borrowed funds is rapidly met by the setting in motion of modern machinery—itself partly brought into existence by the necessity temporarily created. High prices become the rule, until the inevitable glut takes place, when there follows the revulsion to prices which are unremunerative. The fall in values is perhaps increased in rapidity by machinery, but the unwholesome stimulus is not immediately traceable to mechanical appliances.
